In the present four year course of medicine, the student should begin the study of dermatology in the third. He should first see cases. He should be present while patients are examined and discussed by others. His experience is very slight. His knowledge is poor and perhaps prejudiced. He can say nothing for himself. But he will learn much that will be of service in the didactic period. He will have in store a series of mental pictures which the words of the textbook will recall. He will not read blindly. This course of observation may well fill up one semester. If a tutor can be had or the professor is willing to give two hours a week for five or six weeks during the term, instruction may be given in the special anatomy of the skin, as a secretory and excretory organ. A study of the lesions may also follow, to acquaint the student with the language of dermatology.

The second semester is occupied with a systematic presentation of the diseases of the skin. Didactic work is best done along the lines of an authoritative textbook. Eschew quiz compends and students' handbooks. Follow a good treatise in which the subjects are discussed with some fullness. A student can read from forty to fifty pages in preparation for a weekly lesson. Recitations will bring out how much he has extracted from the book. Skillful questioning will emphasize the important points, and judicious comments correct false impressions. The printed page can never take the place of the voice and personality of the teacher. The silent hieroglyphs convey but a feeble impression to human minds. Most people need to be told. They want to be shown.

The resources at our disposal in a metropolitan

city, fail to furnish examples of some rare diseases. There are also many typical and atypical conditions which may be presented in illustration of the text. No representation in either pictorial or plastic art can represent exactly the living patient. Yet it must be acknowledged that the moulages of Baretta are very lifelike. Wax models, I believe, of equal merit are made in this country and in England. But they are not on sale, being preserved in most instances as private records of interesting cases.

Some excellent chromolithographs have been published. None surpass the atlas of Hebra, but that book was issued sixty years ago. It is scarce now and out of print. Crocker's atlas may still be had. Besides, the teacher will have oil paintings and water colors of his own cases.

Photographs show location and peculiarities of the horny layer, such as disquamation and hyperkeratosis. They fail to show color, and show contour but imperfectly. The lens plays tricks with the perspective. Stereoscopic views, when viewed through a proper binocular, are better. Photomicrographs are of great value, if the teacher can obtain such excellent ones as were shown by Professor Fordyce at the American Medical Association in Atlantic City last June.

If a stereopticon is available, and especially that form known as the "reflectoscope," time will be saved and lucidity promoted by throwing the illustrations upon the screen, both chromolithographs and photomicrographs. The microscope should be freely used.

By this time the student becomes sophomore and thinks he knows it all. He needs another term of clinical work to take the fall out of him. Here the lesions of the skin should be minutely described. The close observation necessary, the enumeration of the lesions, their character and distribution, will often suggest the name of the disease, the same as spelling the letters. Very little regard should be paid to the histories by patients. The student should be taught to "look and say." Attention should also be given to the lesions of the visible mucous membranes.

Will this course take up too much time? Not very much. For the teacher, one hour a week throughout the college year; for the student, one hour a week through the third and the first half of the fourth year. The first term is clinical, the seniors occupying the front seats and taking an active part, the juniors sitting behind them and looking on. In the second term, only juniors attend recitations and demonstrations.

This course is suggested for a college graduating not more than twenty-five or thirty students each year. Larger classes would need a corps of teachers and division into sections. The course requires forty-eight to fifty-four hours of the student's time, two thirds of which is clinical. The Association of American Colleges recommends forty hours as a minimum.

273 WEST SEVENTIETH STREET.

**Tuberculous Bone Disease.**—If possible, drain age should be avoided in operating for tuberculous disease of the bones, as the insertion of drains encourages the formation of sinuses. Scrupulous asepsis will generally render the use of drainage unnecessary. *See also, Journal of the American Medical Association, June 1, 1910.*

## Therapeutical Notes.

**Purulent Rhinitis.**—The usual treatment of this condition as it is observed in children is to syringe the nasal fossæ gently with a lukewarm one per cent. solution of sodium bicarbonate or a three per cent. solution of boric acid, the infant's head being inclined forward and downward in order to prevent the solution from passing into the throat and larynx. The application of a two per cent. solution of menthol in oil, touching the mucosa lightly with cotton moistened with the mentholated oil, is also recommended, but better results can be obtained than from the methods described by the insufflation of an antiseptic powder. *La Clinique*, for January 17th., credits the following prescriptions to H. Mendel's *Memento thérapeutique des maladies des organes respiratoires*:

### I.

R Aristol. .... 5i;  
Iodol. .... gr. xlv;  
Sugar of milk, ..... ʒss.

M.

### II.

R Iodoform, ..... gr. xv;  
Gum benzoin, ..... gr. xlv;  
Boric acid, ..... ʒiiss.

M.

### III.

R Zinc sozoiodolate, ..... gr. xv;  
Sugar of milk, ..... ʒv.

M.

If the rhinitis does not yield to some one of these applications, the nasal fossæ should be sprayed with a weak solution of silver nitrate, as follows:

R Silver nitrate, ..... gr. ii;  
Distilled water, ..... ʒi.

M.

**The External Use of Guaiacol in Pneumonia.**—Cain (*Therapeutic Gazette*, xxxii, 1) uses guaiacol externally in the treatment of pneumonia with good results. The remedy is rubbed into the skin, and any part of the body may be selected, but it is said to be absorbed most readily from the abdomen, this site being selected unless there is pain in the chest, when the seat of pain is chosen. The average quantity used for an inunction is twenty minims for adults and ten minims for a child one year of age. The drug is dropped slowly from a medicine dropper and rubbed in with the end of one finger. It is usually all absorbed in one or two minutes. The treatment is never repeated at less intervals than twelve hours, and the average number of treatments is four; no two applications being made in the same place.

**Iodine and Guaiacol Injection for Tuberculosis.** In the treatment of tuberculosis the hypodermatic injection of a solution of guaiacol and iodine in oil has been used effectively in France, such a solution of the following composition being known as Durant's injection:

R Iodine, ..... gr. xv;  
Expressed oil of almond, ..... ʒi;  
Guaiacol, ..... ʒi.

M.

Dissolve the iodine in the almond oil by agitation in the cold and add the guaiacol to the solution.

**The Treatment of Chilblains.**—The following method of treatment is credited to Jadassohn in the *Journal de médecine de Paris*, for January 12th. Bathe the hands and feet in water as hot as can be borne three or four times a day for ten or fifteen minutes at a time. Dry the parts thoroughly, and if the skin is broken and ulcerated wash with alcohol. At night an ointment composed of the ingredients named below is applied by rubbing to the unbroken skin, the ulcerated parts being covered with a layer of it applied on linen:

R	Ichthyol, .....	gr. xv-xxv;
	Resorcin, .....	gr. xv-xlv;
	Wool fat, .....	℥vii;
	Olive oil, .....	℥iiss;
	Distilled water, .....	℥xiiiss.

M.

If the ulceration is extensive the ointment may be applied night and morning.

**The Application of Tincture of Iodine in the Dark.**—In the *British Medical Journal* for November 16, 1907, J. Dunbar-Brunton describes a peculiar property of iodine. If the tincture of iodine is painted on the skin in the dark, or is exposed only to a red light, such as is used in photography, and is covered immediately without being exposed to a white light, it will be absorbed with much greater rapidity than under ordinary circumstances, and it is said not to discolor or blister the skin, even if used for long periods.

**Fluid Iodoform** has numerous uses in medicine. It is a solvent for guaiacol and is miscible with water, alcohol, ether, chloroform, eucalyptol and creosote. It is absorbed readily by the cutaneous surface. Fluid iodoform may be easily prepared according to the following formula, which is taken from *La Clinique*:

R	Potassium hydroxide, .....	35 parts;
	Water, .....	25 parts.
	Dissolve and add—	
	Oleic acid, .....	50 parts.
	Alcohol, .....	30 parts.

To the mixture thus formed then add with constant stirring:

Resublimed iodine, .....	30 parts.
--------------------------	-----------

When the reaction is completed a few drops of solution of potassa are poured in to complete the conversion of the iodine, and the whole is allowed to stand for a few days in the dark, when the fluid iodoform, which forms the supernatant liquid, is decanted.

**Application for Extensive Burns.**—The application by means of a camel's hair pencil to the burned surface of the following analgetic mixture will, the *Journal de médecine de Paris* says, produce a cool feeling and form a protective varnish:

R	Carbolic acid, .....	gtt. xxv;
	White dextrin, .....	℥i;
	Tincture of Sassafras leaves, .....	℥i;
	Spirit of camphor, .....	℥i;
	Lead acetate, .....	gr. xlv;
	Tannic acid, .....	gr. xv;
	Cherry laurel water, .....	℥i.

M.

The dextrin, which has been previously ground to an impalpable powder, is added in small portions at a time to the mixture of tincture of aloes and

spirit of camphor and thoroughly incorporated by rubbing them up in a mortar; the cherry laurel water, containing the lead acetate and tannic acid, being added lastly.

**To Remove Iron Stains from the Teeth.**—The careful application once only of a solution composed of equal parts of crude hydrochloric acid and distilled water, is said by Combe (*Journal de médecine*) to remove the stains on teeth caused by certain preparations of iron. The solution should be applied by rubbing the teeth lightly with cotton wound around a wooden toothpick which has been dipped in the solution.

**Method of Administering Arsenic in Chorea.**—J. Gordon Sharp, in *The Practitioner*, for February, 1908, advocates the administration of arsenic in fairly large doses to stop the movements of chorea in children. By large doses he does not mean a dose of solution of potassium arsenite in excess of 12½ minims, as he has found that when the dose is increased beyond this, the patient may repeatedly vomit both food and medicine. For patients of from eight to fifteen years of age he prescribes the following:

R	Solution of potassium arsenite, ..	℥ cxxl or ℥ ccc;
	Tincture of capsicum, .....	℥ xxv.
	Liquid extract of licorice (B. P.), .....	℥ cxxl;
	Chloroform water, .....	℥ vi;
	Water to, .....	℥ xlii.

M. Sig.: One tablespoonful three times a day immediately after meals.

As will be observed, 240 minims represent a dose of 10, and 300 minims a dose of 12½ minims. Since arsenical solution is of the strength of 1 per cent., each dose of 10 or 12½ minims will represent respectively about 1/10 grain (0.0065 gramme), and 1/8 grain (0.0081 gramme) of arsenic trioxide, and, practically speaking, in a week the patient takes 2.40 or 3 grains (0.156 or 0.194 gramme), according as the prescription has contained 240 or 300 minims.

When he sees a patient for the first time he prescribes 10 minim doses, but if at the end of a week no signs of improvement are seen, he increases the dose to 12½ minims. The latter procedure is not often necessary, for distinct improvement is more often than not observed at the end of the first week on a 10 minim dose. He says it may be laid down, as a good working rule to follow, that, if arsenic is going to do good in chorea, it will show its beneficial action within the first fortnight. When the remedy is doing good, he continues it till the patient can walk along a straight line, and stand on the leg of the affected side with steadiness. This, he says, usually represents a period of three or four weeks, or, at the outside, six weeks.

The patient is kept under observation for three or four days after all movement has ceased, and meanwhile takes the following prescription:

R	Sodium boroglycolate, .....	℥ i.
	Tincture of capsicum, .....	℥ xxv;
	Liquid extract of licorice (B. P.), .....	℥ ss;
	Chloroform water, .....	℥ vi;
	Water to, .....	℥ xlii.

M. Sig.: One tablespoonful three times a day immediately after meals.

## THE GENESIS OF AMERICAN MEDICINE.

In the February number of the *Bulletin of the Johns Hopkins Hospital* there is published an address entitled *Some of the Conditions Which Have Influenced the Development of American Medicine, Especially During the Last Century*, delivered last June by Dr. William H. Welch, of the Johns Hopkins University, at the centennial celebration of his alma mater, the College of Physicians and Surgeons of New York (the School of Medicine of Columbia University). The address is written in Dr. Welch's usual graceful style, which is so well known that it will be read widely, as the importance of its subject deserves. In these strenuous days we are apt to overlook the history of our profession, thus not only neglecting what is due to the memory of our great predecessors, but also omitting to learn lessons which might serve as most useful guides in our present endeavors.

Many of the pioneer physicians of early colonial times did creditable work, some of which has been recorded and must ever prove of service, but it was not until the eighteenth century, and particularly its latter half, that there was any systematic medical education in North America, and even then progressive men resorted to Europe for instruction. This has ever since been the case, but the need for such recourse has constantly been growing less. With the new conditions brought about by the success of the Revolution and the establishment of a solid republic, medical men as well as other citizens became

more self reliant, but they still sought for the educational facilities which Europe alone was capable of holding out. Edinburgh, London, Paris, Vienna, and the German universities became in turn the resort of American students. Each of them has contributed materially toward building up that state of medical knowledge which now seems an earnest that before long we shall be able to repay in great measure our debt to older countries.

The system of proprietary medical schools, for the most part destitute of any substantial connection with a university, came to us from London, but we carried it far beyond the conservative English limitations. These schools, though wholly irresponsible, had the power of granting the medical degree, and nobody questioned the right of a doctor of medicine, of whatever pedigree, to practise. Such schools are still too numerous with us, but in nearly every instance they have been shorn of the licensing power. The system was vicious, however necessary it may have been to begin with, but, as Dr. Welch says, speaking of the early days, "the results were better than the system." Strong men grew out of it, or they grew in spite of it, and Dr. Welch reminds us that such men as John Warren, Godman, Jacob Bigelow (whom he regards as the greatest thinker in American medicine), Dewees, Drake, Torrey, and the Becks "received their entire training in this country"; and we might add many more to that grand array of names. Common sense largely took the place of learning, and we hope that common sense will always lead in our pursuit of medical wisdom.

DERMATOLOGY AND GENERAL  
PRACTICE.

The recent sudden death of Sir Thomas McCall Anderson, M. D., regius professor of medicine in Glasgow University, entails the loss of a man who was at once a prominent dermatologist and a general clinician of renown. We do not recall another recent instance of the association of the two in one individual, save that of the late Dr. William H. Draper, of New York. In this country we knew of Dr. Anderson as a dermatologist before we knew him to have achieved distinction in general medicine; Dr. Draper, on the other hand, was a well known consulting physician before he went deep into the study of skin diseases. Of course, there have been many physicians who, having arrived at a commanding position in general practice, have gradually drifted into a specialty and given up other work. We think, however, that of late years there must have been very few men who have kept up both general and special work. The reason for this

"parting of the ways" is perhaps to some extent what might be termed a commercial consideration, for probably most men realize that their continuance in general practice makes their numerous rivals in that field indisposed to send them patients who require a specialist. It is the old story, and a very human one, of the retailer and the wholesaler. Hence we must look upon the exceptional man who does not bow to the supposed necessity as a man of unusual strength.

The study of cutaneous pathology seems peculiarly qualified to make a physician unusually proficient as a diagnostician. It is true that diseases of the skin are open to the fullest examination, hardly any artificial aids being needed for their adequate inspection and palpation, though, of course, questions concerning their diathetic connections may be as knotty as those that come up in other fields of practice, and their treatment quite as difficult. Nevertheless, skill in dermatology is not easily acquired, and there is always something new to learn. Indeed, there is a playful tradition in the New York Dermatological Society to the effect that a member deserves expulsion if he brings before a meeting a patient whose case can be diagnosed by any other member present; though this is merely a way of saying that only puzzling cases are brought forward, and dermatology has its puzzles in plenty. Great diagnostic skill is acquired, however, in course of time, and that, we presume, is why dermatologists are so often called upon to make a diagnosis when there is a suspicion of smallpox, for example, albeit we do not expect the skin specialist to undertake or suggest the treatment of the case. We all understand that the exanthematous fevers are not skin diseases, but perhaps because of the avidity with which we call the dermatologist into consultation when we suspect smallpox, not a few dermatologists have been tempted to include a consideration of the exanthemata in the textbooks with which they have provided us. While they have thus been tempted, they have undoubtedly taught us much in the field of general practice.

#### RABIES.

An excellent pamphlet has recently been issued by the Bureau of Animal Industry of the United States Department of Agriculture. It is entitled *Some Observations on Rabies*, and has been prepared by Dr. E. C. Schroeder. It is curious that the very existence of rabies—popularly known by the more high sounding name of hydrophobia—should still be questioned and even denied by some medical men. But such is the fact. The doubt and denial seem to rest upon no more substantial ground than the fact that those who proclaim them have never seen

a case, quite as there are those who maintain that chloroform is no more dangerous than ether, simply because they have never observed a death from chloroform. Fortunately rabies is rare and so are deaths from chloroform, and this no doubt accounts for the flimsy basis on which unbelievers entrench themselves. Rabies is indeed a terrible reality, and every means ought to be taken to prevent its spread.

The dog is not the only agent by which the disease may be disseminated, though he is the one that is most commonly active in communicating it, for the reason, as Dr. Schroeder points out, that his association with mankind is practically unrestricted, for he is generally allowed to run at large. As a simple measure of precaution, he should be muzzled. If all dogs were muzzled when they were allowed their liberty, no hardship would be inflicted on any of them, for the muzzled would meet only the muzzled in hostile encounters and injury of the defenseless by their own kind would be done away with. It is only at first, says Dr. Schroeder, that a dog finds the muzzle irksome; he becomes accustomed to it as a colt becomes accustomed to the bit. This sort of showing ought to silence the opposition to muzzling on the part of persons actuated merely by humane feeling for the dog, and certainly that of those who hesitate to humiliate an animal ordinarily so serviceable to man. But, in spite of such opposition, society has the right to protect itself against rabies by all known means.

Dr. Schroeder does not touch upon the Pasteur prophylactic treatment of persons who have been bitten by animals supposed to be rabid, perhaps because he thinks, as we do, that the wisdom of it is commonly held to be *res adjudicata*. Surely enough experience was long ago accumulated to establish the almost invariable efficacy of the treatment when administered under proper conditions. As regards curative treatment, none has yet been discovered; an inoculated person is sure to die a horrible death. We must therefore be insistent in the matter of prevention. "The dog owner who knows what rabies is from experience," says Dr. Schroeder, "if he has the proper consideration for his own welfare and that of his dogs, will be among the first to demand a movement for its suppression, even if this should place restrictions on the freedom of his dogs."

#### THE PATHOLOGY OF CIRCUS AND MUSEUM FREAKS.

The announcement from Ansonia, Connecticut, of the recent death of "the only living skeleton," directs attention to the entire class of freaks, or human prodigies, as they themselves prefer to be called. They have for the medical man a more than ordi-

nary and passing interest. Most of these humble and unfortunate individuals, whose sole means of livelihood is the exhibition of their physical infirmities to a gaping and unsympathetic crowd, are pathological rarities worthy of more serious study than they usually receive. Their mortality rate is high, and many of those recently most famous are already dead or have been retired from public view by chronic invalidism. A few days ago there died in Chicago Maggie Minott, one of the most extraordinary of the nanosomes, or true dwarfs. She was twenty-seven inches high and weighed but twenty-five pounds. Most of these pygmies are types of infantilism and are practically nonsexual. An exception was the comparatively robust and virile "Tom Thumb," who had a vigorous and manly beard, who married, but died without issue. Bass, the "ossified man," also died several years ago. He was a man of unusual intelligence, and his condition was caused by an extreme degree of polyarthritis deformans. He was injured by a careless museum attendant, who let him fall as he was being removed from a carriage, and he never fully recovered. The elastic skin man a few years ago contracted tuberculous disease of the lungs from exposure of his scantily clad body on the drafty stage of dime museums. His was a case of generalized dermatolysis, and he had an amusing trick of drawing the skin of his forehead down over his face like a veil. Closely allied to him was the Russian dog faced man, with features marvelously resembling those of a Scotch terrier. He and the bearded lady, who was wont to convince the most skeptical by a liberal but chaste display of the matronly charms of her rounded and well developed figure, were unusual examples of hypertrichosis. The blonde loveliness of the Circassian beauty, who delighted our unsophisticated younger days, was, of course, a case of albinism, and the "wild men of Borneo" and Barnum's "what is it" we now recognize, in the maturer years of professional experience, as cases of microcephalous idiocy, gathered for the most part from the negro population of our southern plantations.

Most examples of gigantism are cases of acromegaly—as was notably Chang, the Chinese giant, who had the gentle, emotional temperament and, in his last days, the excessive muscular debility so characteristic of this disease. The various "human pin cushions" who have been on exhibition would doubtless present for the neurologist curious areas of anæsthesia and analgesia, which he would properly refer to definite lesions in the spinal cord. Many students of the late Dr. E. C. Seguin's will remember the "blue man" whom he often showed

in his clinic at the College of Physicians and Surgeons. He owed his peculiar cærulean gray hue, approaching the color of a Maltese cat, to the argyria of his tissues produced by the prolonged administration of silver nitrate—a melancholy victim of credulity as to the efficacy of this drug in locomotor ataxia.

In parts of southern Europe there was formerly plied a nefarious trade in maiming and mutilating young children for the purpose of producing distressing deformities to excite pity and thus induce alms. An instance of such mutilation is made romantic use of by Victor Hugo in his story *L'Homme qui rit*. In most civilized countries there are now enacted laws forbidding the public exhibition of monsters and revolting deformities. A more refined and a more humane popular taste now frowns upon such exhibitions, and they are less profitable to their promoters. The profession of museum freak is passing. The genuine *lusus nature* is, however, always a valuable subject of study for the scientific physician, which may add to our knowledge of development of normal types and may possibly illuminate many difficult and obscure problems in pathology.

#### BABY'S BEDCLOTHES.

There are few parents who are not annoyed and even much disturbed by the persistent kicking off of the bedclothes by the baby and younger children. The performance is variously attributed, according to the training of the parents, to a manifestation of the "old Adam" and to indigestion. The universality of this infantile objection to bedclothing seems to us to point to a radical defect in the clothing itself. It is customary to cover the baby with a cotton sheet, a blanket or two, and a silkolene coverlet lined with cotton batting. These absolutely impervious coverings do not permit a particle of air to pass through, and the respiratory function of the baby's skin is quite inhibited. We suggest that a linen sheet be used to cover the baby, although perhaps a cotton one may be allowed underneath; over this nothing could be better than an old fashioned knitted comforter, such as is sometimes seen on baby carriages in cases where the baby has an early nineteenth century grandmother who has learned to knit. Such a comforter will be found somewhat costly to purchase, but not so costly, after all, as sundry visits of the physician to take care of a bronchitis or worse; it will admit air, permit the skin to "breathe," be light on the baby's delicate body, and look as well as all genuine homemade articles look. If the baby has a normal digestion there will be no kicking off of such covering.

## "MONGOLIAN BIRTH MARKS."

Certain congenital bluish spots in the sacral region have been known as "Mongolian birth marks." When they have been observed in children of the white races, there has been the suspicion of a Mongolian strain in the ancestry, though perhaps a remote one. Recently Menabuoni (*Monatschrift für Kinderheilkunde*, 1907; *Berliner klinische Wochenschrift*, September 30th) has observed an instance in a child, seven months old, born in Florence, of white parents. Nothing positive could be ascertained as to the question of a partly Mongolian ancestry. The author, however, is inclined to accept its existence.

## Obituary.

HENRY NEWTON HEINEMAN, M. D.,  
of Paris.

Dr. Heineman died suddenly in Paris on Tuesday, February 11th, at the age of fifty-five. He was a New Yorker by birth and education, and practised medicine in New York until about ten years ago, when he took up practice at Bad Nauheim for the summer and in Paris for the winter. Long before he left New York he had achieved the reputation of an able physician, and he was very popular in the profession.

## News Items.

**Changes of Address.**—Dr. G. W. Stimson, of Philadelphia, to St. Charles place and Pacific avenue, Atlantic City, N. J.

**The Portland, Me., Medical Club** held a meeting on the evening of February 6th. Dr. John Allen acted as host, and the paper of the evening was read by Dr. A. H. Weeks. The subject was Diet in Diabetics.

**Donation to Mt. Sinai Hospital.**—The officers of Mt. Sinai Hospital announce the receipt of a gift of \$20,000 from Dr. Adolph Lewisohn, which is to be added to the endowment fund of the hospital.

**University of California.**—The chair in psychology has been given to Dr. G. M. Stratton, professor of experimental psychology and director of the Psychological Laboratory at Johns Hopkins University.

**The Samaritan Hospital Medical Society, of Philadelphia,** has elected the following officers for the coming year: President, Dr. Collier H. Martin; vice presidents, Dr. G. Morton Ilman and Dr. William A. Steel; secretary and treasurer, Dr. Jesse A. Arnold.

**New Nurses' Home for Harlem Hospital.**—Plans have been filed for a five story and basement building to be erected in East One Hundred and Thirty-sixth street by the trustees of Bellevue and Allied Hospitals, for the nurses connected with the new Harlem Hospital.

**The Annual Election of the Philadelphia County Medical Society** was held recently and the following are the newly elected officers: President, Dr. Albert M. Eaton; vice presidents, Dr. Henry W. Cattell, Dr. Frank C. Hammond, Dr. William Evans, Dr. Robert L. Pitfield, Dr. Henry G. Godfrey, and Dr. John B. Turner; secretary, Dr. William S. Wray; assistant secretary, Dr. Alexander R. Craig; treasurer, Dr. Collier L. Bower; censor, Dr. William M. Welch.

**The Medicolegal Society of Philadelphia** has elected the following officers for the ensuing year: President, Dr. William Ruoff; first vice president, J. Savidge, Esq.; second vice president, Dr. S. P. Gerhardt; secretary, Dr. W. T. Hamilton; and treasurer, Dr. G. M. D. Peltz.

**The Society of Physicians of the Village of Canandaigua, N. Y.,** held a meeting on Thursday evening, February 13th. Dr. John H. Pratt acted as host and the paper of the evening, which was read by Dr. A. L. Beahan, was on The Treatment of the Neck and Shaft of the Femur.

**Buffalo Academy of Medicine.**—The meeting of the Section in Medicine, which was to have been held on Tuesday evening, February 11th, was postponed on account of the sudden illness of Dr. Victor C. Vaughan, of Ann Arbor, who was to read a paper on Proteid Poisons.

**The New York Psychiatric Society** has made arrangements for a series of public lectures. The first of these lectures will be delivered by Dr. Pearce Bailey at the New York Academy of Medicine, on Saturday evening, February 15th, at 8:30 o'clock. The subject is Alcoholism.

**The Society of Former German Students in America** will hold a meeting on Wednesday, February 19th, at 8:15 p. m. Dr. Carl Beck, of 37 East Thirty-first street, New York, will read a paper entitled Pictures from Latin America, a Trip to the West Indies, Colombia, Costa Rica, and Panama.

**The Glens Falls, N. Y., Medical and Surgical Society** held its annual meeting and banquet on Thursday evening, February 6th. A paper on Hemorrhage in the New Born was read by Dr. W. J. Hunt, of Glens Falls, and was discussed by Dr. W. C. Cuthbert and Dr. J. T. Park, of Sandy Hill.

**The Society of Medical Jurisprudence.**—The two hundred and eleventh regular meeting of this society was held on Monday evening, February 10th. The paper of the evening was entitled The Constitutional Aspects of Medical Laws, and was read by Charles A. Boston, Esq., of the New York bar.

**A New Hospital for Rockville, Conn.**—It has been announced that Mr. William H. Prescott has given the sum of \$50,000 to found a hospital in Rockville, Conn. In addition to this gift, members of the Prescott family have purchased a site for the hospital, and will present it to the trustees of the fund.

**Sanitary Officers' Association of Ontario County, N. Y.**—The quarterly meeting of this association was held in Canandaigua, N. Y., on Tuesday, February 11th. Dr. O. J. Hallenbeck, of Canandaigua, read a paper on Rabies, and Dr. B. T. McDowell, of Bristol Centre, read a paper on Typhoid Infection.

**Richmond, Va., Academy of Medicine and Surgery.**—At a meeting held on Tuesday, February 11th, Dr. Beverly R. Randolph read a paper entitled Tic Douloureux: Neuralgia of the Fifth Nerve from a Medical Standpoint, and Dr. Charles R. Robins gave an exhibition of a splint from a fracture of the femur at birth.

**Medical Society of the State of New York.**—Owing to the refusal of Dr. Edward L. Trudeau, of Saranac, to act as president of the society, on account of ill health, the first vice president in numerical order, Dr. Arthur G. Root, of Albany, becomes president for the year 1908, under section 2 of chapter 6 of the by-laws.

**Rochester, N. Y., Academy of Medicine.**—The regular meeting of the Section in Surgery was held on Wednesday evening, February 12th. A paper on the Cause of Pain in the Upper Back was read by Dr. C. Wentworth Hoyt, by invitation, and a paper on Diseases of the Hip Occurring in Adults was read by Dr. Ralph R. Fitch.

**The New York State Civil Service Commission** will hold examinations on March 7, 1908, for the following positions: Physician, Onondaga County Penitentiary, salary about \$480; steward, State Charitable Institutions, \$200 to \$450 and maintenance; woman doctor, State Charitable Institutions, \$200 to \$250 and maintenance.

**Special Sanitation in San Francisco.**—The Board of Health of San Francisco has contributed the sum of \$1,500 towards meeting the expenses of the special sanitation campaign now being conducted in San Francisco. The Public Health and Marine Hospital Service is aiding the city board of health in carrying on this work.

**The American International Congress on Tuberculosis and the New York Medicolegal Society** will hold a joint meeting in Chicago, on June 1st, 2d, and 3d. The local committee of arrangements is composed of Dr. Denslow Lewis and Dr. Thomas Bassett Keyes, of Chicago, and Dr. E. S. McKee, of Cincinnati, the latter having been appointed to take the place of the late Dr. Senn.

**The Medical Society of Washington County, Md.**, held a meeting on Thursday evening, February 13th. Dr. Charles O'Donovan and Dr. A. P. Herring, of Baltimore, read papers on Medical Organization in Maryland, which were followed by a general discussion of the question of a post graduate course for county medical societies. Dr. V. M. Reichard, of Fair Play, opened the discussion.

**The Pathological Society of Philadelphia and the Philadelphia Academy of Surgery** held a joint meeting on Thursday evening, February 13th. The evening was devoted to a symposium on the Parathyroid Gland, papers on the subject being read by Dr. W. H. Halstead and Dr. W. G. MacCallum, of Johns Hopkins University. After the meeting a reception was tendered to Dr. Halstead and Dr. MacCallum at the University Club.

**Appointments in Foreign Universities.**—Dr. D. Barry has been appointed professor of physiology at Queen's College, Cork, Ireland.

Dr. S. Berezowsky has been appointed professor of external pathology at the University of Moscow, Russia, as successor to the late Professor Sinizin.

Professor Jacobi, of Göttingen, has accepted the appointment of professor of pharmacology and director of the pharmacological institute at the University of Tübingen.

**The Tuberculosis Exhibit in Kentucky.**—The tuberculosis exhibit which was held recently in Louisville and afterwards transferred to Frankfort, where it was open to the public from February 3d to February 7th, will be sent to Lexington for its third and last appearance in Kentucky. The exhibit in Lexington will be held on February 21st to 26th under the auspices of the Lexington Anti-tuberculosis Association. The three exhibits in Kentucky are a part of the general campaign against tuberculosis, which is being carried on under the auspices of the National Association for the Study and Prevention of Tuberculosis.

**New York Pathological Society.**—The regular meeting of this society will be held at the New York Academy of Medicine on Wednesday, February 19th, at 8:30 p. m. There will be demonstrations of a rare case of Multiple Tuberculous Abscesses of the Spleen, by Dr. Charles Norris, and a case of Bilateral Renal Tumors, by Dr. J. Larkin. The following papers will be read: A Study of Blood Cultures in Typhoid Fever, by Dr. A. A. Epstein; A New Method for the Quantitative Determination of the Acetone of the Urine, by Dr. T. Stuart Hart; Tuberculosis of the Mesenteric Lymph Nodes; Infections by Human Type of Bacilli, by Dr. A. F. Hess.

**College of Physicians of Philadelphia.**—The Section in General Medicine held a meeting on Monday evening, February 10th. Dr. L. L. Donhauser exhibited a case of ricketts. Dr. Edward H. Goodman read a paper on Leucose as a Test of Hepatic Function, and Dr. G. Ganby Robinson read a paper entitled Gallop Rhythm of the Heart. Dr. William Pepper reported a case of chronic lymphatic leucemia, Dr. E. Burville-Holmes reported a case of fibrinous bronchitis, and a case of pneumococcus arthritis was reported by Dr. Alfred Hand, Jr., and Dr. John H. Jopson.

**An Exhibit Illustrating the Congestion of Population in New York** will be held in the American Museum of Natural History for a period of two weeks, beginning Monday, March 6th. On the opening night Governor Hughes, Mayor McClellan, the Italian Ambassador to the United States, and several of the commissioners of New York City will speak, and on the three following days there will be a general discussion of the various aspects of the congestion of population. One day will be devoted to the presentation of representatives from the various cities of New York State. The object of the exhibit is to make clear the causes of, and the evils resulting from, the congestion of people in crowded areas, and the best methods of dealing with the problems involved. Much interest is being taken in the exhibit, and a large number of the city's citizens and other corporations will participate and contribute.

**Philadelphia County Medical Society.**—At a meeting of the Central Branch, held on Wednesday evening, February 12th, the evening was devoted to a symposium on the Zander Treatment. Mr. Max J. Walter read a paper entitled The Zander Gymnastic Method of Treatment by Mechanical Apparatus, which he illustrated by a lantern slide demonstration of the apparatus. Dr. J. Madison Taylor read a paper on The Field of Applicability of the Zander Mechanical Gymnastics. Among those who took part in the discussion were Dr. Hobart Amory Hare, Dr. Judson Daland, Dr. S. Solis-Cohen, Dr. H. Augustus Wilson, Dr. J. T. Rugh, and Dr. E. A. Newton.

**Mortality of Chicago.**—According to the report of the Department of Health for the week ending February 1, 1908, there were during the week 711 deaths from all causes, as compared with 741 for the corresponding week in 1907. The annual death rate was 17.12 in 1,000 of population. The principal causes of death were: Apoplexy, 8; Bright's disease, 42; bronchitis, 35; consumption, 66; cancer, 32; convulsions, 8; diphtheria, 7; heart diseases, 55; influenza, 46; intestinal diseases, acute, 43; measles, 1; nervous diseases, 17; pneumonia, 139; scarlet fever, 15; suicide, 4; typhoid fever, 8; violence, other than suicide, 23; whooping cough, 1; all other causes, 161.

**The Mortality of the District of Columbia During the Year 1907.**—According to the report of the Department of Health, there were 6,343 deaths from all causes during the year, an increase of twenty-seven over the preceding year. The death rate showed a decrease, however, from 19.35 to 19.25 in 1,000 of population, on account of an increased population. There were 750 deaths from pulmonary tuberculosis, as compared with 781 the previous year, while deaths from pneumonia increased from 503 to 537. The number of deaths from typhoid fever during 1907 was 114, during 1906, 162. There was also during 1907 a diminished death rate from diphtheria and scarlet fever.

**The Medical Association of the Greater City of New York.**—A stated meeting of the association will be held at the New York Academy of Medicine on Monday evening, February 17th. The programme will include addresses by the retiring president, Dr. Thomas E. Satterthwaite, and the president elect, Dr. Robert Tuttle Morris. The subject of Dr. Morris's address is Metaplasia of the Appendix Vermiformis and a New Diagnostic Point. Among those who will take part in the discussion are Dr. Robert F. Weir, Dr. Algernon T. Bristow, Dr. Robert Abbe, Dr. Carl Beck, Dr. Alexander B. Johnson, Dr. Joseph F. Bloodgood, Dr. Franz Torek, Dr. John B. Walker, Dr. Charles H. Peck, and Dr. Albert A. Berg.

**Something New in the Way of Baths.**—The Fleischman Baths, which occupy the three upper stories of the Bryant Park Building, corner of Forty-second street and Sixth avenue, New York, were opened to the public last week, a reception being given to the medical profession and the press on the evening of February 6th. The establishment is modelled after the baths of Diocletian, but with many modern improvements, embracing a number of unique and attractive features. They are fitted up in most elaborate style, and are provided with every kind of bath known to modern balneology. One particularly interesting novelty is the solarium, which occupies the entire top of the building. Sleeping apartments are also provided in connection with the baths.

**The Hodgkins Fund Prize.**—The Smithsonian Institution, Washington, D. C., announces that the Hodgkins Fund Prize of \$1,500 is offered for the best treatise on The Relation of Atmospheric Air to Tuberculosis, to be submitted to the International Congress on Tuberculosis, which will be held in Washington, D. C., on September 21 to October 12, 1908. The treatise may be written in English, French, German, Spanish, or Italian. The essays will be examined and the prize will be awarded by a committee appointed by the secretary of the Smithsonian Institution in conjunction with the officers of the International Congress on Tuberculosis. The right is reserved to award no prize if, in the judgment of the committee, no contribution is offered of sufficient merit. The Smithsonian Institution reserves the right to publish the treatise to which the prize is awarded. Further information will be furnished, on application, by Mr. Charles D. Walcott, secretary of the Smithsonian Institution, Washington, D. C.

**Philadelphia Pædiatric Society.**—A meeting of this society was held on Tuesday evening, February 11th. Rheumatism in Children was the general subject for discussion, the following papers being read: The Etiology of Rheumatism, by Dr. Warfield T. Longcope; The Relation of Rheumatism to Chorea, by Dr. D. J. McCarthy; The Peculiarities of the Symptomatology of Rheumatism in Children, by Dr. Charles H. Dunn, of Boston; the Complications of Rheumatism in Children, by Dr. Alfred Stengel; the Cutaneous Manifestations of Rheumatism in Children, by Dr. Jay F. Schamberg; the Treatment of Rheumatism in Children, by Dr. J. P. Cozier Griffith. After the meeting a reception was tendered Dr. Dunn at the Hotel Stenton.

**Insanity in New York State.**—According to the annual report of the State Commission in Lunacy, the total number of committed insane in the State on October 1, 1907, was 29,093—13,927 men and 15,166 women. The number of inmates of the two criminal asylums at Matteawan and Dannemora was 1,104; the number in private licensed institutions was 977. The net increase for the year was 791. The total number of patients received on original commitments was 6,105. The maintenance cost during the year was \$3.53 a week. A slight increase in the rate of recovery is reported, the percentage of cures on the number of patients received on original commitments being 25.5. The total number discharged during the year as recovered was 1,557, and as improved, 1,236.

**The Philadelphia Academy of Surgery** held a meeting on Monday evening, February 3d. Dr. James K. Young presented a case of Excision of the Clavicle with Perfect Functional Results. Dr. Warren Walker exhibited a case of Tumor of the Orbit. Dr. Oscar H. Allis read a paper entitled The Nonabsorbable Ligature and Suture. Dr. John B. Deaver presented a report of the Saturday Surgical Clinics for Students at the German Hospital During 1906-7. Dr. Henry R. Wharton reported three cases of Fracture of the Proximal End of the Fifth Metatarsal Bone, a case of Multiple Fracture of the Lower Jaw Treated with an Interdental Splint, and three cases of Fracture of the Patella Treated by Open Operation and Suture. Dr. A. C. Wood exhibited an instrument for performing Osteoplastic Resection of the Skull.

**Examination for Surgeons in the Public Health and Marine Hospital Service.**—The United States Civil Service Commission announces an examination to be held on March 4th to secure eligibles from which to make certification to fill a vacancy in the position of acting assistant surgeon, Public Health and Marine Hospital Service, for duty at St. John's River Quarantine Station, Mayport, Fla., and vacancies requiring similar qualifications as they may occur. For the specific vacancy mentioned applicants must be expert in the diagnosis and treatment of yellow fever, and persons who are immune to that disease are preferred. Applicants must be citizens of the United States and must be twenty years of age or over on the date of the examination. Applicants should apply at once to the United States Civil Service Commission, Washington, D. C., for Application Form 1342.

**The Health of Philadelphia.**—During the week ending January 18, 1908, the following cases of transmissible diseases were reported to the Bureau of Health of Philadelphia: Typhoid fever, 115 cases, 21 deaths; scarlet fever, 67 cases, 2 deaths; chickenpox, 36 cases, 0 deaths; diphtheria, 84 cases, 9 deaths; cerebrospinal meningitis, 5 cases, 5 deaths; measles, 75 cases, 2 deaths; whooping cough, 20 cases, 2 deaths; pulmonary tuberculosis, 128 cases, 70 deaths; pneumonia, 139 cases, 105 deaths; erysipelas, 8 cases, 2 deaths; German measles, 3 cases, 0 deaths; septicaemia, 3 cases, 0 deaths; mumps, 2 cases, 0 deaths; scarlatina, 18 cases, 22 deaths. The following deaths were recorded from other than transmissible diseases: Tuberculosis, other than pulmonary, 10; cancer, 10; pneumonia, 1; influenza, 1; other than influenza, 1; under two years of age, 10. The total deaths numbered 657 in an estimated population of 1,450,000, corresponding to an annual death rate of 45.4 per 1,000 of population. The total infant mortality was 124 deaths per year of age, or, between one and two years of age, 41. There were 44 still births, 26 males and 18 females. The total precipitation was 4.1 inches. The temperatures were high, the maximum being 57° on the north, the minimum 25° on the 17th.

**Personal.**—Colonel William C. Gorgas, chief surgeon of the Panama Canal Commission, has been elected an Honorary Fellow of the New York Academy of Medicine.

Sir Thomas McCall Anderson, professor of medicine in the University of Glasgow, died on January 25th.

Dr. Charles S. Crosby, of Columbus, Ohio, is registered at the Philadelphia Polyclinic and College for Graduates in Medicine.

Dr. W. J. Collins has been appointed city physician of Springfield, Mass.

Mr. Malcolm Morris, the well known dermatologist, has had conferred upon him the title of K. C. V. O. (Knight Commander of the Royal Victorian Order).

Dr. Charles A. Phillips has been appointed physician at the new county jail, in Schermerhorn street, Brooklyn.

Dr. Arthur W. de Roaldes, of New Orleans, has been promoted by the French government to the rank of Commander of the Legion of Honor.

Dr. Howard A. Kelly, professor of gynecology at the Johns Hopkins Medical School, has returned from a six weeks' trip to Mexico.

**Army Medical Bill.**—Senator Warren's bill increasing the efficiency of the medical corps of the Army has been passed by the Senate. It constitutes the Medical Department of the Army of the following corps: Medical, medical reserve, hospital corps, reserve corps, and dental corps. The officers are to be a surgeon general, with the rank of brigadier general; sixteen colonels, twenty-four lieutenant colonels, 110 majors, and 300 captains or first lieutenants. The medical reserve corps is created by conferring authority on the President to issue commissions as first lieutenants to graduates of reputable schools of medicine. The rank will carry no rights to promotion. The regular officers under the proposed law are to receive the pay of officers of the line of corresponding grade, and the bill prescribes that promotion shall be by seniority. The House Committee has made a favorable report on the bill but recommends amendments providing for fourteen instead of sixteen colonels, twenty instead of twenty-four lieutenant colonels, and one hundred instead of one hundred and ten majors. The committee also made other slight amendments, among them being one which makes eligible to appointment in the regular corps any contract surgeon who is not over twenty-nine years of age at the date of his appointment as contract surgeon. The bill has been referred to the committee of the whole house and its passage seems assured.

#### Society Meetings for the Coming Week:

**MONDAY, February 17th.**—New York Academy of Medicine (Section in Ophthalmology); Medical Association of the Greater City of New York; Hartford, Conn., Medical Society.

**TUESDAY, February 18th.**—New York Academy of Medicine (Section in Medicine); Buffalo Academy of Medicine (Section in Pathology); Triprofessional Medical Society of New York; Medical Society of the County of Kings, N. Y.; Binghamton, N. Y., Academy of Medicine; Clinical Society of Elizabeth, N. J., General Hospital; Syracuse, N. Y., Academy of Medicine; Ogdensburg, N. Y., Medical Association.

**WEDNESDAY, February 19th.**—New York Academy of Medicine (Section in Genitourinary Diseases); New York Society of Dermatology and Genitourinary Surgery; Woman's Medical Association of New York City (New York Academy of Medicine); Medicolegal Society, New York; New Jersey Academy of Medicine (Jersey City); Buffalo Medical Club; New Haven, Conn., Medical Association; New York Society of Internal Medicine; Northwestern Medical and Surgical Society of New York.

**THURSDAY, February 20th.**—New York Academy of Medicine; German Medical Society, Brooklyn; Newark, N. J., Medical and Surgical Society; Esculapian Club of Buffalo, N. Y.

**FRIDAY, February 21st.**—New York Academy of Medicine (Section in Orthopedic Surgery); Clinical Society of the New York Post-Graduate Medical School and Hospital; East Side Physicians' Association of the City of New York; New York Microscopical Society; Brooklyn Medical Society.

**SATURDAY, February 22nd.**—West End Medical Society, New York; New York Medical and Surgical Society; Union Medical Society, New York; Johns Medical and Surgical Society, New York.

## Pith of Current Literature.

## THE BOSTON MEDICAL AND SURGICAL JOURNAL.

February 6, 1908.

1. The Treatment of Sarcoma with the Mixed Toxines of Erysipelas and Bacillus Prodigiosus.  
By WILLIAM B. COLEY.
2. The Treatment of Leucæmia with the Mixed Toxines of Coley.  
By RALPH C. LARRABEE.
3. General Paralysis as a Menace to Public Safety in Transportation.  
By PHILIP COOMBS KNAPP.
4. The Direct Examination of the Larynx and of the Upper End of the Esophagus by the Lateral Route.  
By HARRIS PEYTON MOSHER.

1. The Treatment of Sarcoma with the Mixed Toxines of Erysipelas and Bacillus Prodigiosus.—Coley speaks of his treatment which he instituted sixteen years ago, based upon the following accepted clinical facts: (1) That inoperable sarcomas, and even carcinomas, have been known to disappear and the patients to remain well and permanently cured as the result of attacks of accidental erysipelas. (2) That inoperable sarcomas have disappeared as a result of attacks of erysipelas produced by inoculation. In all Coley has personally treated about 430 cases of sarcoma with the mixed toxines. In forty-seven of these cases the tumor has completely disappeared; and in twenty-eight cases a period of from three to fifteen years has passed since the disappearance. Twenty-six patients have remained well from five to fifteen years. These figures cover a period of fifteen years, and during this period important improvements have been made, from experience, in both the preparation of the toxines and the method of administration. There is no appreciable risk from this treatment. In only three out of the 430 cases death could possibly be attributed to the toxines. All these three patients were in the last stages of the disease, with extensive metastases and very feeble heart action. Two of the cases presented extensive involvement of the mediastinal glands, and in both the treatment had only just been begun, for two or three days, and sufficient doses had not been given to produce any marked reaction. The patients died suddenly, apparently as a result of an embolus. The author describes the process of preparing the mixed toxines and cites a number of cases.

2. The Treatment of Leucæmia with the Mixed Toxines of Coley.—Larrabee has used the mixed toxines of streptococcus and *Bacillus prodigiosus* in four cases. One showed a degree of improvement amounting to symptomatic recovery, which has now lasted for upwards of four months. Another showed considerable temporary improvement. A third showed improvement in weight and general condition only. A case of the acute lymphatic type was uninfluenced. Although two are still under treatment there does not appear to be much hope of permanent cure. In estimating the value of this treatment, so far as we are justified in doing so from the limited material at hand, says the author, we must compare it with other methods in common use, particularly with arsenic and the Röntgen rays. As to arsenic, it must be admitted that in some cases excellent results follow its use.

though these results are never more than temporary and often fail entirely. In all of the cases under discussion arsenic had been used alone without definite results. In the writer's experience it is rare for arsenic to produce any such prompt and marked results as in two of the cases described. With the truly marvellous effects sometimes obtained with the x rays the writer is unable to say that toxines will compare favorably. Cases have been restored to complete health by the x rays, and, though they always relapse sooner or later, some have remained well for months. The toxines of streptococcus and *Bacillus prodigiosus* are decidedly more painful, and, in the writer's opinion, decidedly more dangerous. It is possible that their effects will prove more permanent. Their great advantage at present is that they can be used in many cases where radiotherapy is not available. The toxines can be administered by any physician or nurse of ordinary skill. They need no costly apparatus and do not require the patient to leave his bed. The author thinks that the results have been encouraging enough to justify further trial. It is in the hope that such further trial may be obtained that these cases are reported in their present incomplete state.

3. General Paralysis as a Menace to Public Safety in Transportation.—Knapp remarks that if men in responsible positions on our railroads were subjected to thorough examination by competent neurologists at regular intervals many of these cases of general paralysis and other brain diseases would be detected and the dangers attendant upon them would be averted. Many railroads demand a careful examination of all applicants for employment, but when this examination is once passed, the man is not examined again unless some striking disturbance is noted. The average railway surgeon, however, will inevitably overlook the slight but significant symptoms that reveal grave brain disease to the neurologist, and, even if he were capable of detecting them, it is only by examinations repeated at regular and rather frequent intervals that the onset of these diseases can be detected, and the danger averted. These affections are not responsible for all the cases of negligence that cause railway accidents, but they form one factor which can be eliminated. The state requires that certain railway employees shall pass examinations to prove that they can tell red from green. Is it too much also to require them to pass periodical examinations to prove that they can instantly understand the different meanings of red and green and act promptly on that knowledge?

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION  
February 8, 1908.

8. The Major Operative Treatment of Middle Ear Suppuration and Its Indications,

By EDWARD BRADFORD DENCH.

9. Indications for Operative Interference in Cerebral Complications Due to Chronic Suppuration of the Middle Ear,

By CULLEN F. WELTY.

### 3. Early and Late Cases of Gastric Ulcer.—

Cheney observes that there is an early stage of gastric ulcer, lasting for weeks or months, during which rigid medical treatment suffices for cure; but the clinical picture of this stage does not correspond to the classical one presented in the textbooks, and the diagnosis at this time must be inferred rather than demonstrated positively. Many cases of chronic dyspepsia, characterized for weeks or months by flatulence, waterbrash, burning and distress after food, where the epigastrium shows tenderness and the test meal shows hyperacidity, are in reality gastric ulcer, even when the faces show no occult blood. Such cases cannot positively be diagnosed as ulcer any more than incipient tuberculosis can positively be diagnosed before bacilli are found in the sputum; yet they deserve routine treatment on suspicion in one instance as truly as in the other. If these dyspeptic cases are allowed to go on indefinitely without treatment or with only haphazard treatment, serious symptoms are likely sooner or later to appear that make the diagnosis clear, but that render the results of treatment much more dubious. In the later stage, commonly described as gastric ulcer, the symptoms are really due to complications rather than to the original disease; (a) to perigastric adhesions, (b) to pyloric stenosis, (c) to gastric dilation and retention, (d) to localized peritonitis, (e) to the opening of a large bloodvessel, (f) to perforation of the stomach wall; complications that lie beyond the realm of medical treatment and have crossed the border line into the surgeon's domain.

### 4. The Ætiology of Epithelioma.—Hertzler

thinks that cancer occurs at that point where irritation and exposure to an alkaline secretion coexist. When a chemical which has the power of combining with the acidophilic elements is injected into a tissue made up of epithelium and connective tissue the epithelium proliferates and invades the connective tissue, simulating the process in beginning epithelioma. The same chemical process which prevents blood from coagulating limits the invasion of one tissue by another. Epithelium everywhere rests on a tissue similar to the membrane elastica of the bloodvessel. It is this layer that confines epithelium within the normal limit. The aberrant growth of cells is but the expression of some disturbance in the chemical relationship of the different kinds of cells. The results of experiments, based on the knowledge of tinctio chemistry, permits us to state in general terms the nature of such disturbance of chemical balance.

### 5. The Ambulatory Treatment of Hip Joint

Disease. Abbott and Fugate describe the so-called German, English, Austrian, and American apparatus and are of the opinion that no one form embodies all the essential phases of mechanical treatment. In order, then, to apply more successfully the principles of fixation, traction, and protection, we are obliged, remark the authors, either to work

some entirely new form of appliance, or to combine the requisite features of those in common use, so that the product will carry the desired treatment into effect. If we take into consideration the matter of cost, which is indispensable in a clinic for the poor, it seems impossible to construct any form of apparatus along new lines of different material from that already suggested without putting it beyond the reach of most patients. They say that the plaster of Paris spica bandage affords the best fixation, the adhesive plaster straps the best traction, and the iron brace which extends beyond the sole of the boot, together with the high shoe on the opposite foot, and crutches, the best protection. The cost of this combination amounts to about \$5.75 for an average sized child. The application of such an apparatus is then described and fully illustrated. The authors have treated about two hundred children with their form of apparatus, and come to the conclusion that the patient is under excellent control, as the apparatus cannot be removed and replaced by the patient or family at will. The appliance can be produced at much less expense than any other that is efficient. The duration of the treatment may be lessened; there is less danger of abscess formation; and the preservation of the joint structure is more certain. The position of the limb can be regulated to a nicety otherwise obtained only through the use of expensive apparatus accurately adjusted by skilled hands and kept constantly under the closest observation.

## MEDICAL RECORD

February 8, 1908.

1. Blood Reactions of Inflammation; and the Diagnostic Prevention of the Terminal Stages of Infections of the Appendix and Gallbladder,  
By W. A. BARTLETT and E. E. SMITH.
2. Stricture of the Eustachian Tube with Its Baneful Consequences Traced to Adhesions in the Fossa of Rosenmüller,  
By W. SOHIER BRYANT.
3. The Organic Factor in High Blood Pressure,  
By ALEXANDER HAIG.
4. Incipency in Tuberculosis from the Standpoint of Sanatoria. The Safety and the Value of the Tuberculin Test when Safeguarded Solely by the Clinical Method,  
By HENRY B. DUNHAM.
5. Benjamin Rush as a Phthisiotherapist,  
By HENRY FARNUM STOLL.
6. The Misuse of the Voice and Its Cure. Vocal Muscles and Resonance,  
By N. F. FOWLER VAN BARGHENE.
7. The Favorable Influence of Small Doses of Arsenic and Bichloride of Mercury in Three Cases of Graves's Disease,  
By LEONARD WELBY.

2. Stricture of the Eustachian Tube with Its Baneful Consequences Traced to Adhesions in the Fossa of Rosenmüller.—Bryant states that the fossæ of Rosenmüller are subject to obstructions and adhesions which interfere with the physiological action of the Eustachian tube through imperfect movements of the tubal cartilage, resulting in stricture of the Eustachian tube. This can be demonstrated by the use of a salpingoscope. Relief from this impediment allows of more effective treatment of the middle ear condition. Early treatment of the obstruction of the fossæ is indicated as soon as the diagnosis is made. The disturbances in the middle ear, which are caused by the pathological conditions in the fossæ, will then yield more readily to appropriate treatment. The results are infinitely more sat-

isfactory than when the fossa is neglected altogether, since an amelioration of the aural condition invariably follows restoration of the function of the tubal mouth and fossa of Rosenmüller. The preliminary treatment of the middle ear condition consists in removing with the curette any lymphoid tissue present. The adhesions which obstruct the fossa must be broken down. The more delicate fibres readily give way to the fingers; the more resistant ones can sometimes be torn with the finger, but occasionally they are so dense that cutting is necessary. Often this process of rupturing adhesions, whether done with the finger or with the knife, must be repeated a number of times, and silver nitrate applied until the mucous membrane has healed and is free from adhesions.

**3. The Organic Factor in High Blood Pressure.**—Haig thinks that high blood pressure may be due to uric acid or to an organic factor or to both in varying proportions. In all cases (if there is time) the uric acid factor is removable; and the organic factor, if due to uric acid, is also to some extent removable. The capillary reflux and the blood pressure alter from day to day and hour to hour with the amount of uric acid passing through the blood; but there are undoubtedly other factors which influence blood pressure, and these may or may not be altered by treating uric acid. By acting on these indications we can in many cases get an answer to important problems affecting the causation of circulation diseases.

**4. Incipency in Tuberculosis from the Standpoint of Sanatoria.**—Dunham speaks in favor of using tuberculin as an agent in diagnosis. He follows Calmette's method. One drop of a 1 per cent. solution, or less at first, of purified tuberculin (*Tuberculin precipitatum*) is instilled into the conjunctival sac of the patient's eye. If the patient is tuberculous, a decided congestion and a watery and sero-fibrinous exudate occurs between three and twenty-four hours later. The percentage of error is probably a little more than with tuberculin used hypodermatically. Until the experience with it covers many more cases than at present, it would be wise to use tuberculin in the usual manner after all negative instillations, when the symptoms still point to the possible existence of the disease. When this is done the initial dose injected need not be as small as would otherwise be deemed advisable. Opportunities for inaccuracy and carelessness in the hypodermatic method of administration are plentiful, but not more so than with many, now familiar, painstaking medical accomplishments. The mode of measuring as used in the Massachusetts State Sanatorium is described. In measuring the doses of tuberculin the greatest care is exercised to insure accuracy. The tuberculin is weighed and then diluted with sterile water to make a solution of such strength that each minim contains one milligram of tuberculin. The solutions are always freshly made. A particular dropper is kept purposely for measuring the pure tuberculin. With this dropper it was repeatedly found that five drops weighed 180 mg. and one drop 36 mg. Consequently one drop of tuberculin thus measured, when diluted to 36 minims with sterile water, gives a solution of which a minim contains one milligram of tuberculin. Ten minims of this solution

(measured with a special dropper) is put into an aseptic glass hypodermatic syringe with enough more sterile water to make about twenty minims to be injected. Estimating that nearly one drop of this might have remained in the needle uninjected, then the patient receives perhaps one half a milligram less than was prepared. As the Saranac tuberculin is always reported as a little stronger or more concentrated than Koch's standard, this loss is considered to have been overcome. The tuberculin used during the first five years at the sanatorium was furnished through the kindness of the Saranac laboratory. Dr. Baldwin describes it as being, if anything, a little stronger than Koch's standard. Latterly some imported Koch's tuberculin has been used.

#### BRITISH MEDICAL JOURNAL

January 25, 1908

1. Some Misleading Abdominal Cases, By D'A. POWER.
2. An Analysis of a Recent Series of One Hundred Consecutive Operations for Acute Appendicitis, By A. H. BURGESS.
3. Intussusception Due to Polypus, By J. L. STRETTON.
4. The Passage of Food through the Human Alimentary Canal, By A. F. HERTZ.
5. Status Lymphaticus in Relation to General Anæsthesia, By W. J. MCCARDIE.
6. A Fatal Case of Status Lymphaticus, By H. HILLIARD.

**2. Appendicitis.**—Burgess reports a series of one hundred consecutive operations for appendicitis. The results are of great interest in connection with the question of early operation in appendicitis and its alleged risks. The cases, forty-five in number, operated upon within four days, yielded no mortality as contrasted with a mortality of twenty per cent. for the fifth day, thirty-three and a third per cent. for the sixth day, twenty per cent. for the seventh day, fourteen per cent. for the second week, and eight per cent. for the third week. These forty-five cases included examples of each of the groups of pathological findings, so that the technique and severity of the operation *per se* was the same as in the latter series. The mortality of the latter, therefore, cannot be ascribed to the operation itself, but is unquestionably due to the inferior condition of the patient at the time the operation was undertaken. The deaths occurred after the operation and in spite of it, but certainly not on account of it. In other words, the mortality which is so often urged against operations in the acute stage really represents the mortality of delay, with the consequent increased toxæmic state of the patient. The lesson to be drawn is not, on account of this mortality, to advise against such operations, but rather to encourage their performance before a stage of serious toxæmia is reached. The series here reported would indicate that, provided operation is undertaken within four days of the onset, the chances of recovery are exceedingly good, and in a previously reported series of forty-seven cases no death occurred after an operation within four days. These results scarcely endorse the view so frequently advanced as to the great danger of operating between the second and fifth days. But even though all these cases recover, yet the earlier the operation the better the recovery. In all the operations within twenty-four hours, and in the majority of those within forty-eight hours the recovery was exactly similar to that after an "internal" operation, without any risk of a weak scar. In most

of those on the third and fourth days drainage was necessary, convalescence was more prolonged, and the chances of a weak scar greater. Of the nine deaths in the series five had general peritonitis, two had diffuse peritonitis with gangrene of the cæcum as well as of the appendix, one a local abscess, and a large abscess extending to the subphrenic region. Surely these fatalities may be justly ascribed to delay rather than to operation; the operation certainly failed to save, but it cannot be said to have materially hastened the inevitable end. The great reduction in the mortality after operations for acute appendicitis that has followed the policy of "interfering" at an earlier period points irresistibly to the conclusion that, were all cases submitted to operation in the early stages of the attack, appendicitis would cease to be a fatal disease.

5. 6. **Status Lymphaticus.**—McCardie states that Paltauf was the first to carefully study and describe the so called status lymphaticus. He found an enlargement of the tonsils, of the lymphatic gland system, of the follicles at the base of the tongue, of the spleen, and lastly an enlarged thymus gland; in most cases also there was narrowing of the aorta. The sudden deaths which occur in patients of this type are ascribed to cardiac paralysis and acute cardiac dilatation. The subjects of the condition are unusually subject to infectious diseases, to death from shock and fright, and to death during anaesthesia. Even comparatively slight lesions in them may end fatally. The results of autopsies are very uniform, being characterized by the presence of a thymous gland of greater or less size, by an enlarged spleen with varying degrees of prominence of its follicles, by tumescence and hypertrophy of lymphatic glands in various regions (especially of the mesenteric, retroperitoneal, and cervical), by noticeable prominence and multiplication of follicles at the base of the tongue and in the pharynx, by enlargement of the tonsils and swelling of solitary follicles and Peyer's patches in the intestine, by a dilated heart (especially the right ventricle), and extremely flaccid cardiac muscle. In addition, there is sometimes found a small heart, contraction of the aorta, and dark fluid blood in the heart cavities. Less constant features are great pallor of the skin, enlargement of the tongue, enlargement of the thyroid gland, infantilism, œdema of the lungs and brain, fatty changes in the liver, and alterations in the bone marrow. So frequently is death during chloroform anaesthesia associated with status lymphaticus that the question has been raised whether death under chloroform ever occurs apart from that condition. The writer gives detailed reports of five instances of death under anaesthesia in cases of lymphatism. All were young and of the flabby type. They seem to suffer more acutely than ordinary patients from shock, and the distance between ordinary deep anaesthesia and danger appears to be shorter. Under chloroform there is often a tendency to grayness of complexion, weak heart action, and shallow heart action, and shallow breathing, so that a chloroform-ether mixture or ether has to be substituted for it, and in most cases the dose of the drug needed to keep up anaesthesia is unusually small. Several members of the same family may suffer from the condition. In most cases there is little or no previous history noted, in

deed, in many the patient was said to have been well and strong. In infants and small children there is frequently stridor causing noisy breathing—"thymic asthma." Among the conditions sometimes associated with lymphatism are exophthalmic goitre, epilepsy, rickets, and infantilism. Death in the case of anaesthesia is always sudden.

4. The Effect of Exercise on the Opsonic Index of Patients Suffering from Pulmonary Tuberculosis, By A. C. INMAN.
5. Note on the Presence and Significance of Certain Rod Shaped Bodies in the Cells of Carcinomatous Tumors, By W. F. ROBERTSON.
6. On the Relationship of Cancer Cells to the Development of Cancer, By J. E. SALVIN-MOORE and C. E. WALKER.
7. Note Upon the Effect of Liquid Air upon the Graftable Cancer of Mice, By J. E. SALVIN-MOORE and J. O. W. BARRATT.
8. Treatment of Graves's Disease with the Milk of Thyroidless Goats, By W. EDMUNDS.
9. A Case of Acute Suppuration in a Thyroid Adenoma Due to the Bacillus Typhosus, By F. G. MELANDRI and T. P. LEGG.

1. **Tuberculosis in Ireland.**—Byers assigns the following causes for the great prevalence of tuberculosis in Ireland: 1. The damp climate. This is of relatively slight importance. 2. Dampness of the soil. While subsoil may be of some importance, yet other conditions are of much greater potency. 3. Emigration is supposed to have left behind a physically inferior population—a race of weaklings, all very susceptible to phthisis. 4. The susceptibility of the Irish to tuberculosis. This is denied by the writer. 5. Poverty and low social condition. 6. Food and drink. There is reason for believing that the increased use of tea and white bread instead of porridge and buttermilk, and the excessive use of alcohol, have lowered the resistance of the people to tuberculosis. 7. Manufacturing industries. The influence of these, as exposing to dust, etc., has been overstated. 8. Want of sanitary reform. 9. The domestic or home treatment of advanced cases of pulmonary tuberculosis. This the writer regards as the most potent cause which has prevented a lowering of the tuberculosis death rate in Ireland. With isolation of these advanced or "open" cases in any country the death rate falls. The measures advocated by the writer are as follows: (a) Compulsory notification. (b) Institutional treatment of advanced cases. (c) Education as to cleanliness, sanitation, and ventilation. (d) Temperance in all things. (e) Inspection of all meat. (f) State control of the milk supply.

3. 4. **Manual Labor in Phthisis.**—Paterson gives the results obtained in the tuberculosis sanatorium with which he is connected, of the introduction of manual labor as a part of the routine treatment of patients suffering from pulmonary tuberculosis. The grades of work are summarized as follows:

lows: 1. Walking from one half to ten miles daily. 2. Carrying baskets of earth or other material. 3. Using a small shovel. 4. Using a large shovel. 5. Using a pickaxe. 6. Using a pickaxe for six hours a day. Patients in grades 2, 3, 4, and 5 work four hours a day. The various grades are each subdivided into sections. The following points appeared to be determined: Suitably selected patients can be gradually trained to do the hardest laboring work for six hours a day, the result being that their general condition is much improved, whilst some lose both their sputum and tubercle bacilli. Certain patients who do not improve on light work show marked improvement on harder work. Patients who have slightly over exerted themselves and are kept at rest for the few following days are subsequently not only not worse, but may be in their own opinion better. The writer therefore concludes that graduated labor is a definite medical treatment for cases of pulmonary tuberculosis, and raises the general health and resisting power of the patients. The combination of rest, pure air, and overfeeding is not the only treatment for chronic pulmonary tuberculosis.—Inman studied the effect of the hard work on the opsonic index of the blood of the patients. His results show that the exercise supplies the stimulus needed to produce artificial autoinoculation, and that its systematic graduation has regulated this in time and amount. With the aid of the opsonic index the stimulus can be regulated with scientific accuracy.

5, 6, 7. **Cancer.**—Robertson, by using the palladium methyl violet method of staining, has demonstrated in a number of cases of cancer, one or more rod shaped bodies somewhat like tubercle bacilli in the protoplasm of many of the epithelial cells. In the examination of thirty-six tumors, these rod shaped bodies were present in every case of cancer. They are straight or slightly curved rods about 3 mikron in length and 0.3 mikron in thickness. The edges are smooth, the ends blunt, and there are no evidences of flagella. The rods do not stain by Gram's method or by the methods used for tubercle bacilli. The writer thinks that there is conclusive evidence that they are parasitic in nature. They present features which prove them to be growing organisms, and they have been cultivated in an artificial medium. The possibility of their being bacilli can be excluded at once. It can be shown that they arise from comparatively large rounded bodies which are certainly not bacterial organisms. They have none of the characters of the *Spirochata microgyrata* of mice cancer. The writer believes them to represent a stage in the life cycle of the protozoan organisms described by himself and Wade as occurring in certain carcinomatous tumors. It is probable that not one species of protozoan organism, but several closely allied species, are the pathogenic agents in the production of carcinomatous tumors. The forms found in carcinoma of the breast present certain characters which distinguish them from those that may be observed in squamous epitheliomata and in intestinal tumors, although the life cycles are essentially the same.—Salvin-Moore and Walker have found that exposure to liquid air at a temperature of  $-196^{\circ}\text{C}$  does not necessarily destroy the possibility of the existence of a mouse

tumor to produce fresh tumors of the same kind in mice into which such frozen tumor substance has been grafted. So that the production of new tumors may not be due to the introduction of the "cancer cells" at all, but upon the action of a virus which is independent of these cells, and retains its activity after being subjected to the temperature of liquid air. It is well known that a number of bacteria are not killed by this temperature. So that it is possible that there exists some such cause as an organized irritant or parasite acting as an agent in the production of cancer. But it is not absolutely certain that the cancer cells are killed by the low temperature.

#### LA PRESSE MEDICALE

##### 1. Technique of Total Abdominal Hysterectomy.

By F. JAYLE.

##### 2. Dilution and Concentration of the Blood, By CHINAY.

1. **Total Abdominal Hysterectomy.**—Jayle says that total abdominal hysterectomy is considered to be more difficult, more serious, and to take a longer time than partial hysterectomy, and that consequently the latter operation is recommended and practised in preference by the majority of surgeons. He acknowledges that the total removal of the uterus is more difficult and takes longer than the partial removal, but denies that it is attended by any more serious danger. At the same time the cervix, which has been left *in situ*, is apt to cause trouble, require subsequent attention, and even prove the seat of a recurrence of cancer. Hence he prefers the total operation, which he describes in detail with the aid of thirteen illustrations. He divides his description into twenty steps, the details of each are given with rather too great terseness to be perfectly clear to any one not accustomed to witness the performance of the operation.

##### 1. Gastric Radioscopy. Ptoisis and Atonic Dilatation of the Stomach. Maintenance of the Reduction of the Ptoisis by Means of the Pneumatic Hypogastric Cushion, By F. ENRIQUEZ.

##### 2. Cancer Caused by the X Rays, By F. JAYLE.

##### 3. Essential Insufficiency of the Heart in the Child, By R. ROMME.

1. **Ptoisis and Atonic Dilatation of the Stomach.**—Enriquez gives a brief account of the utilization of the x rays in the examination of the stomach, together with a description of the technique of their use, and then passes to the consideration of ptoisis and atonic dilatation of that organ. In every case of asthenic dyspepsia in a woman which he has examined he has found the lower border of the stomach very low, from six to twelve centimetres below the umbilicus, while radioscopy examination revealed a very marked ptoisis of the stomach associated with atony and dilatation of that organ. He has found to be of great service in the attempt to keep the stomach in position an air bag bound upon the surface of the abdomen in such a way as to support its lower portion.

2. **Cancer Caused by the X Rays.**—Jayle practically reproduces the twelve observations reported by Porter and White in the *Annals of Surgery* in which cancer developed after an exposure to the x rays.

1. The Syndrome Produced by a Lesion of the Optic Thalamus, By P. HARTENBERG.
2. Gonococcus and Meningococcus, By J. MILBIT and I. TANON.
3. Parasites of Meat Transmissible to Man, By N. GAUTIER.
4. Pathogeny and Treatment of Alveolodental Cysts, By G. MABE.

1. **The Syndrome Produced by a Lesion of the Optic Thalamus.**—Hartenberg presents an excellent description of the symptomatology, anatomy, pathology, and diagnosis followed by a general discussion of the condition produced by a lesion of the optic thalamus, a condition first noticed in 1903, which has since attracted some attention. Briefly, the symptoms presented are: Hemianæsthesia of organic character, slightly marked as regards superficial sensibility, but very pronounced as regards deep sensibility, severe pains in the anæsthetic side of the face, brow, cheek, orbit, limbs, oftener superficial than deep, slight hemiplegia shown by a little facial asymmetry, hypotony and diminution of muscular power, without atrophy or contracture and with reflexes either slightly exaggerated or normal, slight hemiataxia not seriously impeding motor adaptation or locomotion, and choreoathetotic movements. This syndrome may be produced by a lesion of the posterior third of the external nucleus, a portion of the internal nucleus, the median centre and the pulvinar of the optic thalamus, as well as in a small number of fibres of the posterior portion of the internal capsule. The diagnosis may be made through the presence of a hemiplegia with a maximum of sensory and a minimum of paralytic troubles. The accuracy of this conception of the syndrome produced by a lesion of the optic thalamus is not universally accepted.

## LA SEMAINE MEDICALE

January 22, 1908.

1. Has Ulcerative Typhoid Inflammation of the Throat Diagnostic Value? By LÉON BLUM.
2. The Method of Permeation and Its Application to the Exploration of the Digestive Tract and to Treatment of Diseases of the Same.
1. **Has Ulcerative Typhoid Inflammation of the Throat Diagnostic Value?**—Blum states that the ulcerations of the throat which are met with in typhoid fever are characteristic in their aspect and site so that they can hardly be confounded with any other affection of the pharynx. They are usually seated on the upper part of the anterior face of the anterior pillars of the fauces, more rarely on the posterior pillars, on the uvula, or on the velum palati. Both sides are frequently attacked simultaneously and symmetrically; occasionally the lesion is unilateral. It is not exceptional to see several ulcerations scattered over the velum and the pillars. The ulcers are oval, placed obliquely downward and outward, following the direction of the pillars, of variable size, superficial, sharply cut, with red prominent margins and grayish base, not covered by a false membrane, but only with a little mucus, and bleeding readily when touched. They may appear within a quarter of an hour and disappear gradually. On the average they last about ten days. In seventy-six cases the author met with these ulcerations in fifty-seven men and nineteen women.

## MUENCHENER MEDIZINISCHE WOCHENSCHRIFT

January 7, 1908.

1. Relations of Typhus and Paratyphus to the Bile Ducts, By FORSTER.
2. The Cutaneous Tuberculin Test (von Pirquet's) in Children, By FEER.
3. Orthodiagraphic Observations Concerning the Position of the Heart in Pathological Conditions, By DIETLEN.
4. New Contributions to the Ætiology of the Orthotic Albuminuria of Children, By JEHLE.
5. Concerning Specific Hæmolytic Through Isotonic Salt Solutions, By VON DUNGERN and COCA.
6. Concerning a Case of Cholecystitis Paratyphosa, By LOREY.
7. Concerning the Carriers of Typhoid Bacilli in Lunatic Asylums, By GRIMME.
8. The Typhoid Question in Munich, By MANDELBAUM.
9. Modern Methods of Treatment in Gynecology, By RUNGE.
10. Concerning the Treatment of Lysol Poisoning, By FELDMANN.
11. A Brief Contribution to the Subject of Foreign Bodies in the Nose, By KLAUSSNER.
12. The Physician in the Mirror of Poetry, By SALZER.

1. **Relations of Typhus and Paratyphus to the Bile Ducts.**—Forster explains the appearance of sporadic cases of typhoid fever, as well as the endemic and epidemic appearance of the same, by the chronic excretion of typhoid bacilli in the bile of chronic typhoid bacilli carriers. The gallbladder forms the natural place where the bacilli are to be found in these chronic carriers, and the primary indication of treatment is to so treat patients suffering from typhoid fever that no permanent diseases of the gallbladder may be left behind. How this may be accomplished remains for the future to teach us.

2. **The Cutaneous Tuberculin Test in Children.**—Feer speaks very highly of this test as an aid to diagnosis in doubtful cases. The positive result in young children is rarer and more important (prognostically more serious) the nearer we come to infancy, and correspondingly the probability increases that the positive reaction indicates the presence of an affection which is suspected of being of a tuberculous nature. The frequent appearance of phlyctenule and very unpleasant irritation after the ophthalmoreaction contraindicates in his opinion the application of that test in scrofulous children.

4. **Orthotic Albuminuria in Children.**—Jehle says that, as nephritis can be excluded in the great majority of these cases, a milk diet is contraindicated and a strengthening general diet indicated. In addition, there should be physical treatment to increase the general strength, with special attention to muscles of the lumbar region.

6. **A Case of Cholecystitis Paratyphosa.**—Lorey reports a case of cholecystectomy performed on a man, twenty-two years of age, two years after an attack of typhoid fever. Cultures taken from the mucous membrane of the gallbladder immediately after the operation developed a pure culture of the *Bacillus paratyphosus alcalifaciens*. Some time after the operation a fistula appeared, from which there was an abundant discharge of pus stained by bile. Cultures taken from this revealed no paratyphus bacilli, but only the *Bacillus pyocyaneus*. Before the operation the same typhoid bacilli were found in the tissues, but could not be found after the operation.

7. **Carriers of Typhoid Bacilli in Lunatic Asylums.**—Grimme discusses the question of cholecystomy for the purpose of stopping the distribution of typhoid bacilli by chronic carriers, with special reference to the conditions in insane asylums.

10. **Treatment of Lysol Poisoning.**—Feldmann speaks of lysol poisoning as the commonest form met with at the present time because of the ease with which it may be obtained at the drug stores. There are three different kinds of lysol, the paralytol, metalytol, and ortholytol; the most poisonous is a mixture of all three kinds. He reports a case in which the following treatment proved effective very quickly. The stomach was thoroughly washed out, the patient placed in a hot bath, and then packed with hot cloths and hot bottles to prevent a lowering of the temperature, and two injections of 0.001 of atropine were given with an interval of ten minutes between them. The patient recovered consciousness in a quarter of an hour so as to be able to answer questions, and made a complete recovery in a few days.

4. Concerning the Ophthalmoreaction, By WOLFF-EISNER.
5. Brief Remarks in Regard to the Ophthalmoreaction in Tuberculosis, By TREUEPEL.
6. Studies Concerning the Ophthalmoreaction in Tuberculosis, By SCHMIDT.
7. Is there a Specific Precipitate Reaction in Syphilis and Paralysis? By PLAUT, HEUCK, and ROSSI.
8. The Behavior of the Blood Pressure in Muscle Work, By KRONE.
9. The Influence of the Electric Stimulus upon the Distribution of the Blood in the Human Body, By GEISSLER.
10. The Influence of Mud Baths upon the Organs of Circulation, By SCHMINCKE.
11. The District Medical Officer and Infant Mortality, By GROTH.
12. Report Concerning the First Year's Work in the Institution for the Care of Children in Weissenburg, By DÖRFLER.
13. Pathogenesis of Fluor Albus, By NETER.
14. The Physician in the Mirror of Poetry (Concluded), By SALZER.

1. **The Emptying of the Stomach, the Separation of Solids and Fluids, the Behavior of Fat.**—Prym learned from experiments on small dogs that it makes a considerable difference whether pieces of meat are eaten first and fluid then drunk, or fluids taken first and meat eaten later. When the meat is eaten first it is to be found thirty-five minutes after the meal in a coherent mass surrounded by the fluid, while when the fluid is taken first the meat is found scattered through it at the same time after the meal. An hour and a half after the meal the pieces of meat are still together in a mass surrounded by the fluid and the brownish product of the peptically dissolved meat. Fat is scattered throughout in fine particles, which tend to unite and form large drops when the movement of the wall of the stomach is interfered with.

2, 3, 4, 5, and 6. **Ophthalmoreaction.**—Blum states that although the ophthalmoreaction may

indicate the presence of tuberculous disease it does not demonstrate the disease on account of which the test is made is of a tuberculous nature.—Schröder and Kaufmann assert that if no reaction follows the instillation of a drop of a half to a one per cent. solution of Koch's old tuberculin into the conjunctival sac, an active tuberculosis can be excluded with tolerable certainty.—Wolff-Eisner suggests that the name conjunctival reaction would be preferable to the word ophthalmoreaction, which is incorrect and misleading. He then briefly speaks of several recent papers, agrees with Mainini, objects to Klieneberger's conclusions, and protests against reference to the method as that of Calmette.—Schmidt is probably right when he says that sufficient evidence has not yet been collected to enable us to decide in regard to the utility of this test.

7. **Is there a Specific Precipitate Reaction in Syphilis and Paralysis?**—Plaut, Heuck, and Rossi answer this question in the affirmative, and report eight cases in which they have employed this diagnostic test with satisfaction.

9. **The Influence of the Electrical Stimulus upon the Distribution of Blood in the Human Body.**—Geissler investigated this subject on six healthy persons and fifteen diseased. Seventeen investigations were made on the six healthy persons; twelve of them resulted in an increase of the blood pressure, two in a lowering, and in three the blood pressure was not affected. Five of the persons showed an increase of the blood pressure with two exceptions at the first exposure; in these exceptions the blood pressure remained unchanged, and only one person always showed a diminished blood pressure. Forty-three examinations were made of the fifteen sick persons, all of whom suffered from diseases of the heart. The blood pressure was increased during the exposure thirty-two times, sank three times, and remained unchanged three times. A rise, followed by depression, was observed twice, and a depression followed by a rise three times. These observations prove that the electric stimulus has an influence upon the heart and vessels.

10. **The Influence of Mud Baths upon the Organs of Circulation.**—Schmincke says that, on account of its lesser action upon the temperature, the mud bath affects the circulatory system less than a water bath of the same temperature.

13. **Pathogenesis of Fluor Albus.**—Neter reports a cause of fluor albus in a child, three and a half years old, which was demonstrated to be dependent on obstipation.

#### THE JOURNAL FOR NERVOUS AND MENTAL DISEASE.

1. A Study in Tactual Localization in a Case Presenting Astereognosis and Asymbolia Due to Injury to the Cortex of the Brain, By MORTON PRINCE.
2. Tactile Localization and Symbolia: Have They Localization in the Cerebral Cortex? By MORTON PRINCE.
3. General Considerations as to the Nature and Relationships of Hysteria, By R. C. WOODMAN.
2. **Tactile Localization and Symbolia.**—Prince remarks that a stereognosis, that is the perception of form in three dimensions (solidity), is plainly an intellectual process, and to attempt to localize it is to do that for which there is no analogy in the scheme

of cerebral localization. Intellectual judgments are not thus far, according to data at hand, localizable nor likely to be. The nearest approach to such a scheme is that of Marie's new theory of aphasia, according to which aphasia is an intellectual defect and localized in Wernicke's zone. This, to Prince's way of thinking, is the weak point in Marie's theory. It is true that Marie defines the intellectual defect as a special intellectual function, but he fails to define what he means by a "special function," though holding that it is not one of special sensory images—visual, auditory, etc. Though Marie may be quite right, says our author, in his general theory, and in the localization of his intellectual aphasia in Wernicke's zone, his denial that the special intellectual defect consists of a loss of sensorial images may be wrong, and does not seem to be warranted by any evidence that he brings forward; and it may well be, therefore, that if his localization is correct, it is only a localization of sensorial images. This denial of sensorial images in the mechanism of aphasia seems to weaken his theory rather than to strengthen it. Certainly, the localization of broad intellectual processes does not at present rest upon any sound basis of fact. The only conclusive evidence for the localization of symbolia must rest upon clinical observations in which there is found to be loss of power to recognize objects by touch, without loss of the subsidiary sensations and perceptions, and the final demonstration of focal localization in the cortex. No such case, exhaustively examined, with or without anatomical findings, has thus far been reported. In the absence of such a case there is absolutely no logical warrant in attempting to treat symbolia as a sense or concept or function and find for it a localization. Symbolia can only be spoken of and treated as a function symbolically, as a convenient expression to represent a complex process, and although it may be legitimate to do this for purposes of convenience, we are at once led into error when we attempt to localize the symbol. In localizing symbolia, we are interpreting the evidence which in every case involves the impairment of different forms of sensation; and the interpretation which localizes the tactual impressions and makes the symbolia depend upon the loss of sufficient information for judgment fulfills all the logical requirements of the case.

4. The Value of Novocaine as a Local Anesthetic for Subcutaneous Use.  
By J. W. SHERIDAN.
5. Cancer Originating from Bartholin's Gland.  
By LEWIS M. GIBSON.
6. The Symptoms and Etiology of Mania.  
Bruce says in his first lecture that it is a commonly accepted belief that maniacal states are conditions of brain toxæmia or brain poisoning, and that it is

also commonly accepted that hereditary predisposition is the chief predisposing cause of all insanities. As to the exciting causes of mania, there are evidences of bacterial toxæmia: (a) In the blood serum of over 90 per cent. of patients suffering from mania one can demonstrate the presence of an agglutinin which agglutinates the red blood corpuscles of healthy persons. An apparently similar agglutinin is present in the blood serum of many sane and apparently healthy persons. By infecting rabbits with streptococcal and staphylococcal bacteria, a similar agglutinin makes its appearance in the blood serum of the infected rabbits. The presence of such an agglutinin in the blood serum would therefore apparently indicate some form of streptococcal or staphylococcal invasion. As both the sane and the insane may show this symptom of bacterial toxæmia, there must be some further factor in the production of states of mania, and this further factor is probably an inherited or acquired unstable nervous system. This means that the sane and the insane may suffer from similar toxæmias, but whereas the brain of the sane man is stable the toxins produce no mental symptoms, while the brain of the insane man is unstable and readily becomes disordered by toxic action. (b) Although the bodily temperature shows little evidence of toxic disorder, a simultaneous observation of the white blood corpuscles of the patient demonstrates that a state of marked toxæmia exists in nearly every case. (c) The disorders of the alimentary tract are such as one would expect to find in persons suffering from toxic diseases. Further, the bacteriological flora of the alimentary tract is altered in at least 50 per cent. of the subjects of mania. (d) Lastly, the nitrogenous excretion by the urine in the subjects of mania indicates an excess of metabolism similar to that found in known infective diseases.

#### 3. The Value of Leucocyte Examination in Suppurative Conditions Arising from Middle Ear Infection.

Darling has observed a number of such cases and has made exact examinations of leucocytes. He remarks that in uncomplicated cases of acute middle ear suppuration, the total leucocyte count and the polymorphonuclear proportion were higher than normal in 62 per cent. of the cases. In cases of acute middle ear suppuration with mastoid complication the total leucocyte count was above normal in 66 per cent., and the polymorphonuclear cells in 77 per cent. of the cases. Little information of diagnostic value was obtained, because in a single examination of the blood the leucocyte count was in some instances higher in the uncomplicated cases than in those with mastoid complication. In uncomplicated cases of chronic middle ear suppuration, the total leucocyte count in 33 per cent., and polymorphonuclear proportion in 25 per cent. of the cases, were above normal. In cases of mastoid complication with an acute exacerbation, the total leucocyte count was above normal in every instance, while the polymorphonuclear proportion was above normal in 66 per cent. of the cases. In cases of mastoid complication without acute symptoms, the total leucocyte count in 44 per cent. and the polymorphonuclear proportion in 37 per cent. were above normal. In cases of acute and chronic middle

ear suppuration with and without mastoid complication, the leucocyte examination gave information of a general nature as regards the severity and progress of the inflammatory condition, but practically no aid in distinctive diagnosis. In cases of acute and chronic middle ear suppuration, with intracranial complication, the total leucocyte count was above normal in 88 per cent.; the polymorphonuclear percentage was above normal in all of them. If the polymorphonuclear proportion is less than 77 per cent., examination of the blood suggests the absence of an intracranial complication; when the polymorphonuclear percentage is above 86 there is strong presumptive evidence of an intracranial complication. In cases of extradural abscess and sigmoid sinus thrombosis, examination of the leucocytes gave no special features characteristic of the nature and site of the lesion. In the cases of brain abscess, the total leucocyte count did not exceed 14,000. In the cases of septic meningitis the total leucocyte counts were decidedly higher than in those of brain abscess, being in no case less than 17,000. The polymorphonuclear percentage, however, was only slightly higher. A total leucocyte count of less than 14,000 suggests brain abscess; a count of more than 17,000 suggests meningitis.

### Proceedings of Societies.

#### WESTERN SURGICAL AND GYNÆCOLOGICAL ASSOCIATION.

*Seventeenth Annual Meeting, Held in St. Louis, December 30 and 31, 1907.*

The President, DR. CHARLES W. OVIATT, of Oshkosh, Wis., in the Chair.

After a brief address of welcome by Dr. JOHN YOUNG BROWN, on behalf of the local profession, which was responded to by Dr. CHARLES E. BOWERS, of Wichita, Kansas, the reading of papers was begun.

**The Largest Common Duct Stone on Record.**—Dr. WILLARD BARTLETT, of St. Louis, reported this case, and exhibited the stone. The patient was a man, forty-six years of age, with a history of gallstone disease extending over twenty years, which was plainly referable to the common duct. The stone in the duct could be palpated through the abdominal wall; still the man was jaundiced only at times. The stone measured four inches in length by one inch and a half in diameter, and weighed two ounces and a half. The duct was partly sutured and was drained for a month. Five months later the patient was in better shape than he had ever been in his life before.

**The Pathological Gallbladder.**—Dr. B. B. DAVIS, of Omaha, in a paper with this title, said that because a patient had lived through an operation it did not necessarily mean that he was cured. Unless the gallbladder continued to perform its function normally and painlessly, the patient was not willing to consider himself cured. Many patients in whom drainage was instituted had a recurrence of the pain, and a secondary cholecystectomy became necessary. This usually produced relief from all

The following conditions, in the writer's experience, called for extirpation: 1, Adhesions between the gallbladder and the stomach, colon, or omentum. 2, Stenosis or even narrowing of the lumen of the cystic duct, due to old inflammation or pressure necrosis from an impacted stone. 3, Gallbladders with thickened walls due to long continued cholecystitis. 4, When external fistulæ or fistulæ between the gallbladder and the stomach or colon were present. 5, When the gallbladder wall was made up of scar tissue largely displacing the normal muscular coats. 6, When the gallbladder was found filled with mucus, clear or tarry, and there was no fresh bile. 7, In gangrene of the gallbladder. 8, In perforation of the gallbladder. 9, In empyema of the gallbladder, the mucous membrane being usually destroyed over large areas.

Cholecystostomy in the presence of the conditions given, as a rule, did not relieve, and extirpation had to be done later. In most cases the cholecystectomy could be done as a primary operation, without adding to the operative risk. The writer disclaimed taking too radical grounds, since he believed in the retention of every gallbladder that would not be a menace to future comfort.

**The Diagnosis of Duodenal Ulcer from Gallstones.**—Dr. W. D. HAINES, of Cincinnati, said that prominent symptoms in common were pain, vomiting, and accumulation of gas, together with the deleterious influence which these symptomatic manifestations exerted on the general health of the patient. Both complaints were referred to the upper right quadrant of the abdomen, and while the pain in cholelithiasis, which was sharp, decisive, and of sudden onset, was referred to a point opposite the right ninth costal cartilage, it might radiate over the entire right side of the abdomen, and not infrequently found expression in the right shoulder joint. Again, the pain might be the most intense in the region of the tenth dorsal vertebra. Vomiting, if present, was characteristic in that the ejected matter was bile stained, consisting largely of mucus, and it afforded no relief to the patient. Hot fomentations might give temporary relief, but full doses of morphine were usually required to allay the terrible suffering. In duodenal ulcer the pain occurred at intervals and was less sudden of onset and less severe in character. It was described as a burning or gnawing sensation, which might last a few days or continue for months after the primary attack. Unlike the lancinating pains of gallstones, pain in this disease was markedly influenced by the presence or absence of food in the stomach. A certain degree of relief invariably followed the ingestion of a full meal, lavage of the stomach, or the drinking of a quantity of alkaline fluid. The spasm of the pylorus was a frequent accompaniment of ulcer, but wholly unknown in early gallstone cases. Spasm of the diaphragm was evidence of severe pain, which, if referred to the region under consideration, indicated gallstones, as ulcer pain, in the absence of perforation, was not of sufficient severity to produce this symptom. Gaseous distention spoke for ulcer, and the accompanying pain quickly subsided after the expulsion of the gas by eructations or vomiting. Muscular rigidity and local tenderness were present in both ulcer and stone cases. Pain in duodenal

ulcer was due to the passage of acid stomach contents and to distention by gas. Vomiting was of less value as a symptom than either pain or distention, but it was well to remember that vomiting was full and free and followed by marked relief, and ceased promptly in ulcer cases, leaving little depression and no nausea. In late or recurrent gallstone histories vomiting was a prominent feature, and the same might be said of chronic ulcer. The slight transitory disturbance of the one and the invalid dealing influence of the other would materially assist in putting one right in the diagnosis. Hæmorrhage occurring during an attack of gallstones was accidental, but it was prominent as one of the late manifestations in ulcer. Jaundice, like hæmorrhage, was a late symptom and might be present in either of the conditions under consideration. Jaundice following lancinating pain of sudden onset, localized in the upper right quadrant of the abdomen, radiating over the right chest wall or accompanied by pain in the right shoulder, would warrant a conclusion of the presence of gallstones. Constipation was one of the early effects of duodenal ulcer.

In a certain percentage of the chronic and some of the acute cases of stone and ulcer, the distinction would have to be reserved for that erstwhile much used, sometimes abused, method of diagnosis—exploratory incision.

**Peptic Ulcer of the Jejunum.**—Dr. F. GREGORY CONNELL, of Oshkosh, Wis., reported one case of this character in which a secondary gastroenterostomy was performed three years after anterior gastroenterostomy for pyloric ulcer with stenosis.

After a consideration of the subject and an analysis of thirty-nine cases, he concluded as follows: 1. Peptic ulcer of the jejunum was a possible result of gastrojejunostomy. 2. It was probably of more frequent occurrence than the thirty-nine reported cases indicated. 3. It followed the long loop operation more often than the no loop operation. 4. The symptoms might be latent until either acute hæmorrhage or perforation occurred. 5. The symptoms might be chronic and simulate those of gastric or duodenal ulcer. 6. Peptic ulcer of the jejunum should be considered in all cases of return of symptoms after gastrojejunostomy. 7. A symptomless period after the operation was necessary to eliminate a continuation of the condition for which the gastrojejunostomy was performed. 8. A diagnosis could rarely be made before an operation. 9. Prophylactic treatment, aiming to reduce the excess of acidity, should be instituted after gastrojejunostomies for benign conditions, and should be continued for at least six months. 10. The treatment would be either medical or surgical, similar to that for gastric or duodenal ulcer. 11. The possible occurrence of ulcer of the jejunum was an additional reason for performing gastrojejunostomy only where it was positively indicated, namely, by pyloric obstruction.

**Acquired Atresia of the Common Duct Due to a Gallstone.**—Dr. JOHN C. HANCOCK, of Delmar, after referring to the literature, reported the case of a woman, aged sixty-six, who gave this history in connection with her illness, which had existed two years and nine months. Family history, negative. Previous history, also negative except for severe headaches and occasional palpitation. Her present

illness began in October, 1901, with sudden and severe pain in the abdomen in the region of the ninth and tenth ribs, vomiting, purging, chill, and fever. The attack lasted from one to two days, and subsequent prostration delayed the patient's return to her home for two weeks. Three weeks after her return home she began to experience excruciating soreness in the same region as before, and extending around the ribs to the right shoulder blade and shoulder. This condition, with variations in severity, lasted all winter. In April, 1903, she experienced a sensation of pushing and grinding, starting in the right side. This extended across the back and abdomen, and lasted two weeks. With this girdle pain the patient was confined to bed and jaundice set in. This had persisted. From a weight of 116 pounds the patient gradually lost 36 pounds, but the loss of strength was not so great in proportion as the loss of weight. With the jaundice there were loss of appetite, itching, dulness of the sensorium, many slight chills, and once a severe attack with high fever. The stools, which had been dark, became clay colored. The urine had been scanty and high colored most of the time since jaundice set in, and the patient had to micturate as often as four times a night. In April, 1904, her feet began to swell slightly, and later the body. The bowels moved three times in twenty-four hours, and the movements were accompanied by pain in the lower abdomen. At present the patient suffered no longer with headaches, but was faint at times, had enjoyed a fair appetite until the last few days, was not troubled with belching or heartburn, had some shortness of breath, without cough, and occasional palpitation, which, however, antedated the illness in question. The stools were watery and cream colored.

Examination revealed a short, jaundiced woman, with a body spare above the waist, prominent abdomen, and slightly oedematous lower extremities; pulse 90; temperature 99.2°; respiration 16; sclera bile tinged; lungs negative; heart apex beat in the third interspace inside the nipple; and no murmurs. The liver dulness extended from the fifth rib in the mammillary line to four fingers' breadth below the costal margin. Ascites was present and prevented the examination of other abdominal viscera. No tumor was made out or any tenderness, except near the costal margin on a line between the ninth rib and the umbilicus. The circumference of the abdomen at the umbilicus was 96 centimetres; the urine was high colored and acid, with a specific gravity of 1.032; bile was present; of albumin there was the slightest possible trace, but no sugar; there were occasional hyaline casts and some small round epithelial cells, probably from the kidney; there were a few abnormal red blood corpuscles, with an abundance of various forms of large epithelial cells, probably from the bladder, and pus corpuscles. The next day six quarts of ascitic fluid were removed, having a specific gravity of 1.011, and showing a trace of albumin. The abdomen was now soft and permitted of satisfactory palpitation. The liver was felt to be hard and smooth for three fingers' breadth below the costal margin on the right, and more than halfway to the umbilicus and thence across the epigastrium transversely, where the edge could be easily grasped between the fingers and thumb at the same time. Further exam-

trium, slightly to the right of the median line below the liver margin, numerous hard nodular masses, slightly tender and movable, were made out. The liver itself was not tender, but the region of the gallbladder was still markedly so. The spleen was enlarged. The examination of the abdomen otherwise was negative.

After carefully considering the hazards of an operation, in the presence of jaundice and more particularly ascites, the patient decided upon an operation. Accordingly, through a vertical incision through the right rectus, the abdomen was opened. The residual ascitic fluid was removed. The viscera were found congested, and in addition in the upper right quadrant densely adherent. So far the hæmorrhage was not extraordinary, but upon separating the adhesions the fresh surfaces bled freely and continuously, in spite of ligatures and the fact that no demonstrable vessels were severed. A hard, cirrhotic liver and several enlarged lymphatic glands were readily found, and a small contracted gallbladder was identified. From this stage on, further exploration had to be done almost entirely by palpation, on account of hæmorrhage. A movable stone, of the size of an olive, was felt in the common duct, but no evidence of malignant growth was made out. By this time the hæmorrhage had become alarming and had so obscured the field that the attempt to incise the common duct to allow for bile drainage had to be abandoned. The field was packed and the abdominal wound partly closed. The patient left the table showing signs of shock and hæmorrhage, and died fourteen hours later from complete exsanguination in spite of calcium chloride, etc.

Shortly after death a partial autopsy was made. The abdominal cavity was found entirely free from clots, although the pelvis contained free blood. The findings at the operation were confirmed. The gallbladder was contracted to the size of an olive. The common and hepatic ducts were greatly enlarged. At the junction of the cystic and common ducts was found a cicatricial contraction of the cystic duct. In the bladder and duct were several small flat concretions. Upon removal of the large stone from the lower end of the common duct the condition of atresia of this duct was discovered. The lower end of the duct was perfectly smooth without a sign of opening into the duodenum and might be likened to the blind finger end of a rubber glove. The bile tract, a portion of the liver, the duodenum, and the pancreas were removed *en masse*, and examined both macroscopically and microscopically. Macroscopically, the liver presented the appearance of hypertrophic cirrhosis, but under the microscope the changes of atrophic cirrhosis were present. Macroscopical examination showed atresia of both the common duct and that of Wirsung. The duct of Santorini could not be found, and there was entire absence of the papilla on the duodenal side. Microscopically, the ductus choledochus, that of Wirsung, the pancreas, and the duodenum showed chronic inflammatory changes, but no malignant elements. Bile was present in the common duct. The stone was found to be a mulberry calculus, composed almost entirely of cholesterolin, and made up, superficially at least, of bile pigment and calcareous salts.

Dr. CHARLES H. MAYO, of Rochester, Minn., said that he and his brother had done twenty-two hundred operations on the gallbladder and ducts. Of

this number, there were over six hundred cholecystectomies and about three hundred operations on the common duct. A few years ago they had a leaning toward the removal of the gallbladder if there was any disease of the mucosa perceptible, while now they were inclined to leave the gallbladder if the cystic duct was open. The operation, however, of the removal of the gallbladder as a secondary operation was not so serious as operations on the common duct which might be necessitated later, after the removal of the gallbladder. They believed that the removal of the gallbladder resulted later in the majority of cases in distention of the common duct. They had had five cases of the reformation of stones in the common duct, and three of them after the removal of the gallbladder. In all of the series he only recalled two cases in which, after the primary operation of removing gallstones from the gallbladder, stones had reformed in that viscus.

Dr. C. H. WALLACE, of St. Joseph, Mo., reported the case of a woman upon whom he had operated some two years before for the removal of stones in the gallbladder. The gallbladder itself was found in a fairly good condition; the mucosa was not diseased, not very much enlarged, and the walls were not much thickened. A number of stones were removed and drainage was established. A few weeks ago this woman began to have attacks again. In the third or second attack she passed three or four small gallstones. This was a case in which the question arose as to whether, in doing a second operation, the gallbladder should be removed or drainage again tried. He thought surgeons got the impression from those who did a large amount of gallbladder surgery that if in a given case there was a healthy gallbladder, with stones in it, where the mucous membrane was not diseased, if the stones were removed and the gallbladder was drained, the patient could be assured that he or she, as the case might be, would get well. Occasionally, however, such patients returned, and the guarantee of such a prognosis could not be given now with as much assurance as in former years.

Dr. J. E. SUMMERS, of Omaha, said that seven or eight years ago he had reported a case in which there was a tight stricture at the lower end of the common duct, and also one of the cystic duct, the common duct acting as a reservoir. The liver was very much hypertrophied, as was also the spleen. The technique employed was to open the common duct and to make an anastomosis between this and the duodenum. The patient made a good recovery after a long time. Mayo Robson had also reported one or two of these cases, which Dr. Hancock had not mentioned in the literature of the subject, and he thought Dr. William J. Mayo had reported one or two others.

Dr. JAMES E. MOORE, of Minneapolis, said that within the past six months he had seen two cases of gallstones of great interest. One was a case of Dr. Mayo's and the other a case of his own. Both patients had practically the same symptoms. In his case there were first the ordinary gallstone symptoms. The patient was operated upon, the stones were removed, and the gallbladder was drained. Later the patient had a recurrence of symptoms, and at the operation gallstones were found and cholecystectomy was performed. The interesting feature about his case and Dr. Mayo's was that these women were

at the present time suffering again from gallstone colic. What should be done? The only hope was that there was a stone or stones in the common duct that might be reached. He had not yet operated in a case of that kind. He thought, however, it was quite possible that these stones might be in the hepatic duct, because in the case in which he had operated and removed the gallbladder, the stones were many, small and soft, looked like millet seeds, and evidently came down from the gallbladder at that time. He had the feeling that this woman would surely have trouble some time in the future. It was only two years since he did the cholecystectomy, and now she was having serious symptoms and very grave attacks, but without jaundice.

Dr. JOHN C. MORFIT, of St. Louis, reported two cases of bowel obstruction due to gallstones, which had occurred within sixty days of each other in the last year. A woman of eighty had acute obstruction of the bowel, with finally total obstruction when he saw her. The bowel was obstructed at about eighteen inches above the ileocaecal valve by a stone an inch and a quarter in diameter and an inch and a half long, which evidently came from the gallbladder. She made a very satisfactory immediate recovery from the operation. Pneumonia, however, developed on the eleventh day, and she died on the fifteenth day after the operation. A post mortem examination was not made, but the question arose as to the pathological anatomy in the region of the gallbladder. How did this stone get into the intestine? Did it come through the common duct, or did an inflammatory anastomosis occur between the gallbladder and some portion of the alimentary canal? He believed that there was, as a result of preexisting inflammation, an ulceration or anastomosis between the gallbladder and duodenum, or possibly some portion of the small intestine.

Within a few weeks thereafter another woman, fifty-six years of age, presented herself with exactly the same condition. He was able to strike a stone in practically the same situation at once, the stone being of the same size and consistence. The intestine was opened by a linear incision, the stone liberated, and the incision closed, and the patient made an uneventful recovery.

**Harrington's Solution in the Treatment of Suppurative Inflammation of the Knee Joint.**—Dr. J. E. SCAMMERS, of Omaha, said that it had been proved experimentally and clinically that Harrington's solution would kill all the common germs met with in surgical practice in from twenty seconds to a minute, and was not caustic. After thorough washing of the hands in hot soapsuds and then immersing them for two minutes in this solution, if cultures were taken, there should be an entire absence of germs. Even when there was no preliminary washing of the hands before their immersion in the solution for two minutes, the results were remarkable. The author reported an interesting case in which this solution was used, and said that, while his experience with Harrington's solution was not great, it could be used very advantageously in infective wounds where it was applicable. After thorough surgical cleansing of a wound or abscess cavity, the solution was allowed to remain in contact with all its surfaces for from three to five minutes; it was

then irrigated or sponged away, and the particular wound dressed as required. Any one who would try Harrington's solution would like it. It had, besides its established antiseptic property, the power, when applied to a raw surface, to produce a copious discharge of serum, thus aiding the washing away of noxious elements from the wound.

Dr. CHARLES H. MAYO emphasized the value of Harrington's solution as an antiseptic, and said that it was one of the best and least destructive ones we had in use for suppurating wounds.

**The Removal of Gallstones in the Common Duct through the Lesser Omentum.**—Dr. M. L. HARRIS, of Chicago, said that the gallbladder and its contained stones might be enucleated without much difficulty, but should the common duct harbor stones, it might be impossible to reach them by the usual route. He did not now refer to those cases in which a stone was lodged in the ampulla of Vater, and could be reached by the transduodenal route, but to those in which the stone was in the upper part of the duct or movable within the duct, and which, owing to the pyloric end of the stomach having been drawn to the right by adhesions, lay behind this portion of the stomach as well as the duodenum. In two cases of this kind which had come under his care, after a somewhat prolonged fruitless effort to reach the common duct in the usual way, he had succeeded in reaching and removing the stones by following a new route through the gastrohepatic, or lesser, omentum above the pyloric end of the stomach. These two cases he reported in detail. The advantages of this route in these cases were the great saving of time over attempting to work one's way through an almost impossible mass of adhesions and the lessened dangers of injuring the duodenum or other structure.

**Removal of the Whole or a Part of the Humerus.**—Dr. E. M. SALA, of Rock Island, Ill., said that the removal of the whole or a part of the humerus was a comparatively safe operation, and one which should be carefully thought of in all cases where amputations were formerly the first aid to the injured in serious disturbances of the humerus. He thought too many arms had been sacrificed in the past that might have been saved had the surgeon cared to try an extirpation of only the diseased portion of bone. Almost any kind of an arm was better than none. Before the days of aseptic surgery there possibly was some excuse for amputating anything in the shape of an arm that looked bad, but to-day, with the aid of aseptic and antiseptic methods, we were expected to attempt greater feats in surgery. That it was possible for a whole or a part of the humerus to be extirpated, and the patient given a useful hand or forearm, was beyond doubt. One third of the upper end of the humerus might be removed, and the patient appear as though nothing had ever happened to the upper extremity, except shortening on that side. The whole humerus might be removed without serious disturbance to the hand and wrist, especially if care was exercised in saving the musculospiral nerve in its separation from the bone.

Dr. ROLAND HILL, of St. Louis, Mo., showed what could be accomplished by conservation in the treatment of lesions of the humerus, and that short arms

weeks ago he presented a case before the St. Louis Medical Society, in which the upper part of the humerus was involved and was removed. This man had been taken ill in 1892, with a septic condition involving the upper part of the humerus and also the glenoid part of the scapula. In the winter of 1905 he came to the city and Dr. Morfit opened the joint and removed some dead bone from the upper part of the humerus and also from the scapula. The patient returned home at the end of five weeks in a much better condition, but in the summer he began to be septic again. He came back to the speaker in July, at which time there was a constant discharge of pus. He opened up the parts freely, removed the head of the bone, and cleaned out the cavity thoroughly and packed it. The patient improved very much and went home, but the joint did not heal up. There was a constant discharge, and in March, 1906, the patient came back with the idea of having the arm removed. Dr. Hill made one more effort to save it, opened it up, curetted the diseased tissue, and found there was some necrosis at the head of the bone extending down to the medullary cavity, which was removed. He thoroughly dried it and sterilized the parts with carbolic acid and alcohol and then filled the cavity with Moorhof's bone mass. The arm was not dressed again for a week. In about six weeks thereafter healing had taken place. The arm was kept in a sling for four months, at the end of which time the patient was able to use it and had been using it ever since.

Dr. W. D. HAINES, of Cincinnati, mentioned a case in which, in 1898, he removed almost the entire humerus from a boy, ten years of age, who had a number of sinuses along the outer surface of the arm. No attempt was made to save the periosteum; the entire bone was removed down to within two inches of the condyles. The patient has to-day a useful arm. He endorsed this method as preferable to primary amputation, and said that amputation, if really necessary, could be done later.

**The Surgical Treatment of Hallux Valgus with Bunion.**—Dr. CHARLES H. MAYO, of Rochester, Minn., recommended for this condition a curved incision, base down, over the metatarsophalangeal joint. The bursa of the bunion was preserved and left attached to the base of the first phalanx. The head of the metatarsal bone with the greater part of the bunion was removed. The bursa was turned into the joint in front of the cut end of the bone. Thus was utilized a ready formed bursa to prevent joint fixation, a result which was obtained in other joints with difficulty by turning fatty tissue into a joint to develop such a bursa. The general function of the joint was nearly perfect and continued to be so after many years.

**Early Restoration of Function after Excision of the Elbow in Tuberculous Cases.**—Dr. G. G. COTTAM, of Rock Rapids, Iowa, related the history of the case of a young farm laborer who suffered from tuberculosis of the capitulum humeri, with ankylosis of the elbow, in which it was very desirable to secure early use of the arm. Excision by Kocher's incision was used, and through this means and by radical modification of the after treatment from that usually employed, together with the fact that the operation was done before the soft parts were extensively involved, brought about the desired

result, the patient being able to do the heavy work of his occupation after the eighth week. The paper concluded with the following summary of the points involved in producing such an outcome: 1, Early operation, that is, as soon as it was certain that the disease was present and not yielding to conservative treatment. 2, Choice of a method of operating which preserved the integrity of all the important nerves and muscles. 3, Removal of sufficient bone to insure free mobility. 4, Immobilization in the extended position, with maintenance of the angle of deflection. 5, Active motion at the end of three weeks.

(To be concluded.)

## Letters to the Editors.

### METCHNIKOFF SOURED MILK.

NEW YORK, January 23, 1908.

#### To the Editors:

In your issue of January 4th you publish an extended and very interesting article by Dr. Henry G. Piffard, called A Study of Sour Milks, in which he makes reference to our preparation known as bacillac. Ordinarily I should make no reply to an article of this kind, but several physicians who have come to have a friendly feeling toward us through benefits which their patients have derived from our preparation have urged me to respond, that there may be no misunderstanding in the matter. It is for this reason solely that I write you this communication, with the request that you will give it a place in your columns in answer to Dr. Piffard's comments on our product.

Dr. Piffard states that in microscopical examinations of our product made in June, July, and August last he found yeast germs, in the face of the fact that the papers issued by this company distinctly state that yeasts are not used in the preparation of our milk. He also states that he found *Oidium lactis* in each instance. As neither of these germs is pathogenic, Dr. Piffard's discovery becomes of importance only from the standpoint of purity and exactness in representation of the contents of the bottles. He states, too, that the name of the bacillus employed was not given on the labels, but he assumes that it was the *Bacillus bulgaricus*. I am somewhat surprised that the learned gentleman did not immediately recognize the bacillus employed in implanting this milk, in view of the fact that he so readily identified yeast germs and *Oidium lactis*. Our labels state that the milk is sterilized and then implanted with the bacillus isolated by Metchnikoff. In a paragraph following the above mentioned comments, Dr. Piffard accounted for the yeast he found by saying that the bottles used resembled "second hand beer bottles" and that they had probably been "insufficiently sterilized." The milk itself is also commented on as "not of the highest quality."

This company is the American licensee of *La Société le ferment*, of Paris, which is conducted under the scientific patronage of Professor Metchnikoff, of the Institut Pasteur. Our product of soured milk is made in the strictest accordance with Professor Metchnikoff's directions, and only a pure culture of the lactobacillus isolated by him is utilized. Yeast is not employed in any way. Every possible scientific precaution is observed to make

this milk an absolutely pure product. On the 19th of August last, for good and sufficient reasons, the management of this company made a change in the head of the bacteriological department. Since then we are confident no one can successfully question the purity of this milk.

This company has never used "second hand beer bottles." Last winter the gentleman then managing the company, desiring to secure quickly a large quantity of black bottles, made a contract for several hundred gross of Dublin stout bottles, which, properly purified and sterilized, make an excellent container. A part of this order fell as legacy to the present management. It may be that at the time Dr. Piffard states, through improper supervision of operatives, some of the bottles were not properly sterilized, but such is not the case to-day. Every container that we use is twice washed in the most approved bottle washing machinery, and is then completely sterilized. In fact, our bottles are twice sterilized, once immediately after washing, and then again on the day on which they are used for bottling the milk.

Dr. Piffard states that during the month of October he made an examination of this milk, and that at that time he found neither yeast nor *Oidium lactis*. This, I think, is a confirmation of my statement that subsequent to the nineteenth of August no fault could or can be found with our product.

In reference to the quality of the milk used by this company, we can only say that we have always used the best that can be had, furnished by our treasurer, Mr. L. B. Halsey, the founder of the Sheffield Farms Milk Company and the principal owner of the White Clover Farms Milk Company. To-day, notwithstanding that we purchase hundreds of gallons of milk weekly, we pay six cents a quart for our milk supply. Its quality and richness are well attested by the quantity of cream removed from it by our creaming machines.

Dr. Piffard states that in June last he sent the advertising papers of this company to Professor Metchnikoff by registered mail, asking him if he endorsed the statements contained in these papers. Dr. Piffard's article states that he had received no reply to his letter. In reference to this, I can only say that I am glad he sent the papers by registered mail, as that circumstance leaves no doubt that Professor Metchnikoff received them. Why no reply has been made by Professor Metchnikoff I cannot imagine. Perhaps it is because the professor deemed no reply necessary, the papers in question so faithfully representing his own views and those of the directors of *Le Ferment* in Paris, with which he is so intimately quite familiar.

THE LEECH RACHLETT COMPANY OF NEW YORK.

W. M. Bates,

General Manager.

COMPRESSED AIR FOR DILATING THE  
EUSTACHIAN TUBE.

Copyright, 1907, S. C. February 2, 1908.  
The Leech Rachlett Company.

It is quite possible that there may be nothing new in this method of dilating the Eustachian tube but it is certainly new to me, since I have never seen it

used elsewhere, or have heard the suggestion made. Having long been impressed with the failure of the Politzer method of inflation, it occurred to me that an attachment to the cut-off of the compressed air tube could easily be made and forty or fifty pounds of pressure be applied for the dilatation of the tube. This attachment was simply constructed out of the large end of a rubber Eustachian catheter. This catheter had the bayonet socket joint so that the union was firm, and it also accurately fitted into the mouth of an ordinary Eustachian catheter. I have been using this method of dilating the Eustachian tube for some considerable time now, and I have never injured either the tube or the drum membrane, even when as much as forty or fifty pounds pressure was used, and its advantage over the old Politzer's bag is so apparent that it has only to be tried by any one to be appreciated. Of course the use of any method of inflation presupposes that the tube is intact throughout its course, because if there is any abrasion, as occurs after the use of the Eustachian bougie, emphysema of the neck or face will inevitably result.

W. PEYRE PORCHER.

## Book Notices.

*The Prolongation of Life. Optimistic Studies.* By ELIE METCHNIKOFF, Subdirector of the Pasteur Institute, Paris. The English Translation Edited by P. CHALMERS MITCHELL, M. A., D. Sc. (Oxon.), Hon. LL. D., F. R. S., Secretary of the Zoological Society of London, etc. New York and London: G. P. Putnam's Sons, 1908. Pp. xx-343.

The work before us is a translation of Metchnikoff's *Essais optimistes* published last year in Paris. We can conceive of no good reason for this change of title except possibly from a commercial standpoint. It is not very many years since Metchnikoff revolutionized pathology by his promulgation of the doctrine of phagocytosis. Decried by nearly every contemporary pathologist at the time, it was soon found that the facts cited by the author were easily verifiable, and there was no gainsaying the conclusions to be drawn from them. Metchnikoff's next important work, on *Immunity*, still further added to his scientific reputation. His *Nature of Man* (English title) for lay reading is a work that should be read by every adult, containing as it does a mass of information not readily accessible to the general public, and many facts but little known even to the profession.

Lastly, the volume before us appeals to both the profession and the public. The author divides his subject into nine parts, of which the first six are respectively as follows: The Investigation of Old Age; Longevity in the Animal Kingdom; Investigations of Natural Death; Should We Try to Prolong Human Life; Psychical Rudiments in Man, and Some Points in the History of Social Animals. The first three of these are devoted to the causes that lead to premature decay, and the present unnecessary curtailment of existence. Briefly, the chief of these causes is intestinal autointoxication due to the development of toxins (indol, skatol, etc.) in the large intestine through the influence of the bacteria

factive bacteria. In the fourth part he indicates the remedy, to wit: the free ingestion of antagonistic bacteria capable of inhibiting the growth of the peccant putrefactive organisms and especially the free use of a certain Bulgarian microbe with which his name has been commercially associated. The fourth and fifth parts are exceedingly interesting. The seventh, eighth, and ninth are Pessimism and Optimism; Goethe and Faust; Science and Morality. We cannot but feel that it would have been better if these parts had been omitted or rather perhaps published separately, as we have laid down the volume with a sense of depression rather than elation, and in a pessimistic rather than an optimistic frame of mind.

The translation is a fairly good one. We have noticed a few crudities of expression and several evident mistranslations.

*Manual of Physiological and Clinical Chemistry.* By ELIAS H. BARTLEY, B. S., M. O., Ph. G., Professor of Chemistry, Toxicology, and Pædiatrics in the Long Island College Hospital, etc. Third Edition, Revised and Enlarged, with Fifty-one Illustrations. Philadelphia: P. Blakiston's Son & Co., 1907. Pp. 202. (Price, \$1.)

Dr. Bartley's short manual of medical chemistry needs no introduction. In its third edition the consideration of the clinical side of the subject has been considerably broadened and enlarged. The author aimed to write a brief yet sufficiently explicit working textbook for students, and he has succeeded very well. Practising physicians who do their own laboratory work will also find the book useful as a practical guide. The tabular statements of many important facts add to the value of the book and aid the student's memory considerably. There are some minor defects and omissions which may be overlooked in view of the general excellence and practical character of the book.

*Materia Medica, Therapeutics, Pharmacology, and Pharmacognosy.* Including Medical Pharmacy, Prescription Writing, and Medical Latin. By WILLIAM SCHLEIF, M. D., Demonstrator of Medical Pharmacy in the Medical Department of the University of Pennsylvania. Series Edited by BERN B. GALLAUDET, M. D., Demonstrator of Anatomy and Instructor in Surgery, College of Physicians and Surgeons, New York. Philadelphia and New York: Lea Brothers & Co., 1907. Pp. 470.

It is not creditable that this book has seen a third edition without some attempt being made to correct the many errors of type and of statement that are to be found in its pages. Some of these errors verge on the ludicrous, like that one on page 28, where keratin is stated to be "A substance made from the wing cases of insects." Under the heading Medicated Wines, on page 42, the single prescription printed calls for 15 c.c. of wine of colchicum in 100 c.c. of peppermint water. By an amusing typographical error on page 60 musk root is represented to contain "volatile oil and resin, in combination with asafœdita, ferrous sulphate, and arsenic trioxide"; but the printer cannot be blamed for naming the garden lettuce as the source of lactucarium on the following page; and it is hardly fair to teach medical students that "cocaine is the hydrochloride of an alkaloid obtained from coca" (page 79). In addresses and papers much has been said of late of the adequate knowledge of pharmaco-

logy possessed by the newer graduates of medical schools, and it is not to be wondered at if the charge is true, considering the sort of information to be obtained from textbooks of the character of the one under review.

### Miscellany.

**Deaths of Physicians in 1907.**—During 1907 2,013 deaths of physicians in the United States and Canada were reported, equivalent to an annual death rate per 1,000 of 16.1, based on an estimate of 125,000 practitioners. This death rate does not differ materially from those of the previous five years, which were, respectively, 1906, 17.2; 1905, 16.36; 1904, 17.14; 1903, 13.73, and 1902, 14.74. The age at death varied from twenty-one to ninety-seven years, the average being fifty-eight years, eleven months, and eighteen days. The number of years of practice of the decedents varied from the first year of practice to the seventieth, with an average of thirty years, four months, and twenty-one days. About 11 per cent. of those who died were members of the American Medical Association. One hundred and ninety deaths were attributed to general infectious, malignant and nutritional diseases and tuberculosis; 225 to diseases of the nervous system; 107 to diseases of the digestive system; 243 to diseases of the circulatory system; 181 to diseases of the respiratory system; 140 to diseases of the genitourinary system; 83 to miscellaneous diseases, and 141 to violence. Chief among the assigned causes of death were heart diseases, 234; cerebral hemorrhage, 184; pneumonia, 147; nephritis, 120; tuberculosis, 66; senile debility, 50; malignant disease, 42; typhoid fever, 32; appendicitis, 31; septicæmia, 20; diabetes, 18; gastritis, 13, and influenza, 11. Two deaths each are reported from diphtheria, scarlet fever, and tetanus. The deaths from violence during the year numbered 141; of these 87 were due to accident, 37 to suicide, 16 to homicide, and 1 physician expiated the crime of murder in the electric chair. Falls, and steam and street railways accidents each were responsible for 25 deaths, poison for 12, drowning for 5, gunshot wounds and runaways for 3 each, and burns, suffocation, and automobile accidents for 2 each. The 37 physicians who are reported to have killed themselves chose the following methods: Gunshot wounds, 13; poison, 9, 4 of which were from morphine, 2 each from carbolic acid and potassium cyanide, and 1 from strychnine; 5 cut their throats; 3 hung themselves; stab wounds, drowning and jumping from heights each caused 2 deaths, and 1 was due to asphyxiation. Of the decedents 85 were between the ages of twenty-one and thirty, 253 between thirty-one and forty, 247 between forty-one and fifty, 344 between fifty-one and sixty, 404 between sixty-one and seventy, 331 between seventy-one and eighty, 172 between eighty-one and ninety, and 12 more than ninety years of age. One practitioner had been in practice for seventy years, 50 for from sixty to seventy years, 267 for from fifty to sixty years, 558 for from forty to fifty years, 961 for from thirty to forty years, 1,381 for from twenty to

**Public Health and Marine Hospital Service:**

*Official list of changes of stations and duties of commissioned and noncommissioned officers of the United States Public Health and Marine Hospital Service for the week ending February 8, 1908:*

- BLOUNT, B. B., Acting Assistant Surgeon. Granted leave of absence for thirty days from January 31, 1908.
- BOGESS, J. S., Passed Assistant Surgeon. Relieved from duty at St. John, N. B., and directed to proceed to Chicago, Ill., reporting to the medical officer in command for duty and assignment to quarters.
- BROOKS, S. D., Surgeon. Granted an extension of leave of absence for ten days, on account of sickness.
- CARMICHAEL, D. A., Surgeon. Directed to proceed to Fort Stanton, N. M., and St. Louis, Mo., for special temporary duty; upon completion of which to rejoin his station at Buffalo, N. Y., returning via Washington, D. C.
- CORPUS, G. M., Passed Assistant Surgeon. Directed to proceed to Austin, Tex., for special temporary duty; upon completion of which to rejoin his station at Galveston, Tex.
- EARLE, B. H., Passed Assistant Surgeon. Granted leave of absence for seven days from February 4, 1908.
- FOSTER, A. D., Passed Assistant Surgeon. Granted leave of absence for one month from January 10, 1908.
- FRANCIS, EDWARD, Passed Assistant Surgeon. Granted extension leave of absence for seven days.
- HICKS, W. R., Acting Assistant Surgeon. Excused from duty without pay, December 15 to 23, 1907, inclusive.
- KEATLEY, H. W., Acting Assistant Surgeon. Granted leave of absence for five days from January 14, 1908, under paragraph 210, Service Regulations.
- McLAUGHLIN, A. J., Passed Assistant Surgeon. Relieved from duty at Naples, Italy, and directed to proceed to Manila, P. I., reporting to the Chief Quarantine Officer for duty.
- MONCURE, J. A., Acting Assistant Surgeon. Granted leave of absence for thirty days from February 20, 1908.
- SPRAGUE, E. K., Passed Assistant Surgeon. Granted leave of absence for ten days from February 11, 1908.
- SPRATT, R. D., Assistant Surgeon. Leave of absence granted Assistant Surgeon Spratt for twenty-one days from January 14, 1908, amended to read for eleven days only.
- STONER, G. W., Surgeon. Directed to proceed to Malone, N. Y., for special temporary duty; upon completion of which to rejoin his station at Ellis Island, N. Y.
- WALKER, R. T., Acting Assistant Surgeon. Granted leave of absence for four days from February 16, 1908.
- WICKES, H. W., Passed Assistant Surgeon. Granted leave of absence for two days from January 28, 1908, under paragraph 189, Service Regulations.
- WOLLENBERG, R. A. C., Assistant Surgeon. Relieved from duty at Ellis Island, N. Y., and directed to proceed to Naples, Italy, for duty.
- YOUNG, G. B., Surgeon. Detailed to represent the Service at the third annual convention of the American Society of Inspectors of Plumbing and Sanitary Engineers to be held at Chicago, Ill., February 10 to 12, 1908.

*Board Convened.*

A board of medical officers was convened to meet at San Francisco, Cal., February 3, 1908, for the purpose of making a physical examination of an officer of the Revenue Cutter Service. Detail for the board: Surgeon H. T. Austin, chairman, and Passed Assistant Surgeon C. H. Gardner, recorder.

*Casualty.*

Acting Assistant Surgeon Stacy D. Williamson died January 25, 1908.

**Army Intelligence:**

*Official list of changes in the stations and duties of officers serving in the medical department of the United States Army for the week ending February 8, 1908:*

- BOUCKE, JAMES, First Lieutenant and Assistant Surgeon. Relieved from duty as Surgeon of the U. S. A. Transport *Kilpatrick*, and ordered to Fort Leavenworth, Kansas, for duty.
- CARTER, E. C., Major and Surgeon. Appointed a member of an Army retiring board at Fort Leavenworth, Kansas.
- MILLER, E. W., First Lieutenant and Assistant Surgeon. Relieved from duty with the Army of Cuban Pacifica-

tion, and assigned to duty as Surgeon, U. S. A. Transport *Kilpatrick*.

MORSE, A. W., Captain and Assistant Surgeon. Appointed a member of an Army retiring board at Fort Leavenworth, Kansas.

MUNSON, E. L., Major and Surgeon. Left Fort Sheridan, Ill., on ten days' leave of absence, with permission to apply for an extension of twenty days.

TALBOTT, E. M., Captain and Assistant Surgeon. Relieved from duty at Fort Leavenworth, Kansas, and ordered to duty with the Army of Cuban Pacification.

**Navy Intelligence:**

*Official list of changes in the medical corps of the United States Navy for the week ending February 8, 1908:*

- McCLURG, W. A., Medical Director. Commissioned a medical director from June 16, 1907.
- McDONELL, W. N., Passed Assistant Surgeon. Detached from duty at the Naval Hospital, New York, N. Y., and ordered to the naval recruiting station, Chicago, Ill.
- ORVIS, R. T., Surgeon. Commissioned a surgeon from March 1, 1905.
- WHEELER, L. H., Assistant Surgeon. Ordered to the naval training station, Newport, R. I.

**Births, Marriages, and Deaths.***Married.*

BARUCH—EMMETAZ.—In New York, on Wednesday, February 5th, Dr. Herman B. Baruch and Miss Rosemary Emmetaz.

CUNNINGHAM—TREANOR.—In San Jose, California, on Friday, January 24th, Dr. W. Edgar Cunningham and Miss Edith Cecelia Treanor.

KISHLER—HOLLINGSWORTH.—In St. Marys, Ohio, Dr. W. G. Kishler, of Wapakoneta, and Miss Henrietta Hollingsworth.

McDUFFIE—HELMER.—In Asbury Park, New Jersey, on Wednesday, February 5th, Dr. Marshall Williams McDuffie, of New York, and Miss Hattie W. Helmer.

*Died.*

ALLEN.—In Cobleskill, New York, on Friday, January 31st, Dr. Peter A. Allen, aged sixty-nine years.

BARRON.—In New York, on Thursday, February 6th, Dr. John Conner Barron, aged seventy years.

BECKHAM.—In Shelbyville, Kentucky, on Saturday, February 1st, Dr. Beverly M. Beckham, aged eighty-two years.

CDARHOLM.—In Brooklyn, on Friday, February 7th, Dr. David L. Cedarholm, aged forty-five years.

DEE.—In Buckport, New York, on Sunday, January 26th, Dr. W. H. Dee, aged seventy-nine years.

DYE.—In Philadelphia, on Monday, February 3d, Dr. Frank Hazzard Dye, aged thirty-two years.

FLEWELLING.—In Somerville, Massachusetts, on Friday, January 31st, Dr. Douglass S. Flewelling, aged forty-six years.

FULLER.—In Bellefontaine, Ohio, on Thursday, January 30th, Dr. S. W. Fuller, aged ninety-four years.

GREEN.—In Pittsburgh, Pennsylvania, on Monday, January 27th, Dr. J. J. Green, aged sixty years.

HOLCOMBE.—In Great Barrington, Massachusetts, on Saturday, February 1st, Dr. Charles Clifford Holcombe, aged seventy-eight years.

LECKNER.—In Detroit, Michigan, on Thursday, January 27th, Dr. Frank P. Leckner, aged forty-eight years.

McCREIGHT.—In Bastrop, Louisiana, on Saturday, January 5th, Dr. William R. McCreight, aged seventy-one years.

MILLARD.—In Chicago, Illinois, on Saturday, February 1st, Dr. Samuel R. Millard, aged ninety-two years.

MORRISON.—In Fort Worth, Texas, on Tuesday, January 28th, Dr. Claude A. Morrison, aged thirty years.

NEAT.—In New Albany, Indiana, on Saturday, February 1st, Dr. Thomas C. Neat, aged sixty-seven years.

PAINE.—In Oneida, New York, on Sunday, February 2d, Dr. Ridley C. Paine, aged fifty-one years.

ROEHLER.—In Chicago, Illinois, on Thursday, January 30th, Dr. Henry D. Roehler, aged thirty-four years.

SHARP.—In Arcade, New York, on Wednesday, January 29th, Dr. Henry P. Sharp, aged fifty-three years.

VARNER.—In Evansville, Indiana, on Wednesday, January 29th, Dr. W. T. Varner.

#### SOME OF THE TRIUMPHS OF SCIENTIFIC MEDICINE IN PEACE AND WAR IN FOREIGN LANDS.

*With Suggestions up on the Necessity of Important Changes  
in the Organization of the Medical Department  
of the United States Army.*

BY LOUIS LIVINGSTON SEAMAN, A. B., M. D., LL. B.,  
F. R. G. S.,  
New York.

Late Major Surgeon, United States Volunteer Engineers.

If any doubting Thomas questions that the crowning glory of the profession of medicine is the prevention of disease rather than its cure, a visit to the American tropics should convince him of his error. For centuries the continents, both north and south of the equator, have stood in constant dread of dysentery, bubonic plague, malaria, and yellow fever. Terrible epidemics of the latter have ravaged the coastwise cities in spite of rigid quarantines, for prior to 1902 the nature of its transmission was not understood, and effective quarantine was impossible where the stegomyia mosquito thrived. Only a few years ago, in the harbor of Santos, thirty-one ships of almost every nationality rode at anchor for months without a living creature aboard, many of their masters and crews having fallen victims to "yellow Jack," with little possibility of replacing them.

"Fifteen men on the dead man's chest,  
Yo-him, ho, and a bottle of rum,  
Drink and the devil had done for the rest."

only in this instance the devil was yellow fever, which was of such frequent occurrence as to scarcely excite surprise. The South American coast was dreaded by the mariner more than the Spanish main in the days of the pirate bold and the buccaneer, so much so that the Lloyds often refused to underwrite vessels visiting these hotbeds of infection. But how is it to-day? Through the brilliant discoveries suggested by Finley, of Havana, and proved by the commission headed by Major Reed, the true method of its transmission was established and its eradication became a possibility, although in the prosecution of their experiments the majority of the members of the commission fell martyrs to the disease. What Dr. Wood, Dr. Reed, and Dr. Gorgas accomplished in its extinction in Havana and Santiago, and Dr. Gorgas repeated so effectively in the Canal Zone, as you heard him so graphically describe at a recent meeting of this Academy—Dr. Cruz stopped

cated with even greater success in Bahia, Rio de Janeiro, and Santos, the most prolific culture grounds of the disease in the world, because their sanitary problems were there more difficult. Not until the last named scientist was given absolute control in his own department, however, were his labors crowned with success. A terrible epidemic of the fever had visited Rio and Santos, the commerce of Brazil was paralyzed, the population of the cities decimated. Foreign capital was deserting, and the outlook was most gloomy. Millions of dollars were required for its extermination, and, after violent political opposition, Dr. Cruz was ultimately given control of his department, with correspondingly fortunate results, for in a comparatively short time the country was free from disease. He established an admirably equipped department of sanitation, with a corps of over 2,300 well paid, uniformed men, whose sole duty was to fight yellow fever and bubonic plague, and who carried out their orders with almost as much celerity as the members of the fire department do in this city. Horses stood harnessed in their stables, ready to be hitched to ambulances and disinfecting carts, loaded with the necessary equipment for isolating cases and purifying the surroundings, so that the moment a new case was reported it was isolated by double screens, and the spread of the disease was effectually prevented. As a result, desirable immigration is no longer frightened away, foreign capital is flowing in to develop the limitless resources of the land, commercial interests have enormously increased, and the material and financial gains parallel those of humanitarian character. Brazil demonstrated the axiom that prevention is better than cure, and that, as a financial proposition, it pays to give the medical officer adequate authority in his own department.

The splendid work of Cruz in eradicating yellow fever has been equally successful in his campaign against bubonic plague, which for years had ravaged the coast with serious mortality. The final extinction of both these transmissible diseases in South America will soon be an accomplished fact, if the present policy of prevention and sanitation is maintained. In addition, Cruz established a school of experimental medicine in Rio, rivaling similar institutions in Europe and America, which will justly give Brazil an enviable position in the scientific world. A large corps of assistants are constantly occupied in the preparation of the various sera used in the prophylactic or curative treatment of bubonic plague, diphtheria, typhoid, and other diseases, and distributed over the country on the demand of physicians. The stables of the animals used in the prosee-

cution of this work are marvels of cleanliness, and in the operating room asepsis is observed as faithfully as in a modern hospital.

Rio de Janeiro maintains an excellent institution for the preparation of vaccine virus, also a medical college, which is to celebrate its centenary during this coming summer. It is admirably equipped with laboratories, especially for the study of hygiene and sanitation. Its Academy of Medicine is a most select body, and the walls of the lecture rooms of the college are graced with life size portraits of its leading professors. Aseptic precautions are observed so carefully in some of the hospitals that operating arenas are separated by plate glass partitions from the remainder of the room, so as to completely isolate them from contaminating atmosphere, where the students are seated.

The most serious defect observed in all the institutions of South America was the lack of trained nurses. Many of the hospitals in these old countries were formerly convents, and the labor of nursing was performed by the members of the various sisterhoods. These women, although often inspired by high motives, lack the skill necessary in the care of serious diseases, or for obtaining the best results in the after treatment of operations. And here I may be pardoned for a moment's digression to pay a word of tribute to my old traveling companion and friend, Dr. Nicholas Senn, whose sudden and lamented death recently shocked the world.

It was my privilege to circumnavigate the continents of Africa and South America with him, visiting the coastwise cities and hospitals en route, and penetrating through the jungle to the interior, wherever railway connections permitted.

While crossing the Peruvian Andes in September, near Lake Titicaca, 12,000 feet high, and La Paz, the highest city in the world, he was seized with the attack of *soroche* or mountain sickness that hastened his end. In passing from the Pacific Ocean through the Cordillerian and Andean ranges, over the great divide that separates it from the Amazonian slope, we rose to an altitude of nearly three miles in fifteen hours. The tremendous tension put upon the circulatory system in this already rarified atmosphere resulted in an attack of acute cardiac dilatation, with its distressing sequelae, aggravated by bronchitis contracted in the Straits of Magellan.

To dwell upon the achievements of this great man would only be to repeat that with which the scientific world is already familiar. Aside from his remarkable originality in the field of surgery, Senn was a naturalist of deep learning, well versed in the flora and fauna of almost every land in the habitable globe. His fame was world wide. His capacity for work exceeded that of any man I have ever known. He was a close observer, a conservative operator, an eloquent clinical lecturer, and in the emergency of war served his country faithfully and well. In his death America has lost an honored son, science a distinguished pioneer, and the world a gentle friend, whose fame will linger longest in the short and simple annals of the poor.

You have so recently heard of the brilliant results attained by Dr. Gorgas in the Canal Zone that a rehearsal of them is unnecessary. But the great les-

son pointed out at the time of his lecture. It must be remembered that during the first year of our occupation of the Panama district disease ran rampant, so much so that at one time the abandonment of the entire enterprise was considered. It was then proved that sanitation was the fundamental problem requiring solution, even before the engineering question could be solved. The original Isthmian Commission included no member of the medical profession, but was composed entirely of politicians and officers, ignorant of sanitation and hygiene, who ignored or so limited the authority of the chief sanitary officer as to render the enforcement of his regulations and measures impossible. This officer, Dr. Gorgas, was subordinated to the governor of the zone, to the chief disbursing officer, to the chief of the Bureau of Materials and Supplies, to a Mr. Grunsky, to the commission, to the Secretary of War—subordinated, in fact, to the seventh degree from the source of authority—just about as the medical officer of the United States army is, under the decrepit system under which he is compelled to serve to-day.

The chairman of the Legislative Committee of the American Medical Association, Dr. Reed, says:

"Here was Dr. Gorgas, recognized as the foremost authority in the world in the solution of the peculiar problems pertaining to tropical sanitation, subordinated to a series of other subordinates, all of whom were confessedly ignorant of the very question with which he was most familiar."

"The working of this wonderful mechanism," continues Reed, "is interesting. Thus, if Major La Garde, superintendent of Ancon Hospital, makes a requisition for supplies, he must make it in due form, take it for approval to the chief sanitary officer, then to the governor of the zone, then to the chief disbursing officer; whence it goes to the commission at Washington; then to the Mr. Grunsky as committeeman; then back to the commission; then, if allowed, bids are advertised for; awards are made; the requisition is filled under the supervision of a purchasing agent notoriously ignorant of the character and quality of medical and surgical supplies; the material is shipped to the Isthmus, consigned to the chief of the Bureau of Materials and Supplies, who notifies the disbursing officer, who notifies Colonel Gorgas, who in turn notifies Major La Garde, who applies to the quartermaster—the boss of a coral—for transportation, and, so much of the stuff as is in the judgment of, first, the governor, next the chief disbursing officer, next the commission, next, and more particularly, Grunsky, the committeeman, ought to be allowed to the superintendent of Ancon Hospital, finally arrives, or does not arrive, at its destination, where the necessity for its use has probably ceased."

This is no fanciful picture; it is exemplified in practically every requisition that went forward and illustrates the tortuous course of the regular military channel, as it now exists in the United States Army.

And what was the natural consequence of this wretched system at Panama? A costly epidemic—the death of some members of the commission and of many laborers—a stampede of the remainder that threatened the success of the entire canal scheme and caused a delay of nearly a year in its completion, and the loss of interest on its heavy investment, that would have paid for the sanitation of the zone for years. Not until the imminence of failure dawned upon the Washington authorities was a medical officer made a commissioner, with authority to carry out his sanitary measures. The success resulting from this power being conferred upon our honored colleague again demonstrated the wisdom

of making a medical man supreme in his own department; a truth Congress was for once forced to recognize.

Foreign governments foster their medical discoverers; ours does not. When Pasteur made his brilliant discovery of the microbic origin of disease and found the magic key that unlocked the secrets of infection, the French government recognized his great work by placing him at the head of an institution under governmental patronage that enabled him to more successfully prosecute his experiments and researches. When Koch discovered the bacillus of tuberculosis, he was a comparatively unknown country practitioner, but his government placed him at the head of a department with abundant means to continue his work; it sent him to Africa to investigate the rinderpest, and after the successful solution of that problem sent him once more to the dark continent, where for the past two years he has been conducting a heroic battle against those dreaded diseases of the African tropics, sleeping sickness and malaria.

In Africa I met Dr. Ollwig, Koch's chief assistant, who, in his scientific battle with malaria, is carrying out the two policies suggested from an etiological point of view: (1) The destruction of the anopheles by ridding the surrounding jungle as far as possible of its breeding places, and (2) the neutralization of the plasmodian parasites by hypodermic and internal administration of quinine, continued for many months. Favorable results have thus been obtained, although the difficulties of exterminating the mosquito have not yet been overcome. The period during which the infected stegomyia continues as a source of danger in the transmission of yellow fever is limited to fifty days, whereas the infected anopheles retains its power of infection for three years, thus making the task of eradicating malaria far more difficult.

The results of Koch's investigations of tripanosomiasis are already well known to the medical profession. The infected tsetse fly is undoubtedly the most dangerous enemy of man and beast, where it exists, as up to the summer of 1906 the bite of an infected fly was invariably fatal. Its ravages in a belt of territory near Victoria Nyanza in the year we were there resulted in a fatality among the natives of over 200,000, many districts being almost depopulated. Horses, mules, cattle, antelopes, zebras, and wild buffaloes died in countless numbers. The zone of these depredations was rapidly increasing, and for that reason the German government sent Professor Koch to study the habits of the fly and discover, if possible, a method for its extermination.

How can the Japanese government look upon the health of its citizens? When Kitasato, after careful research and experimentation, discovered the bacillus of bubonic plague, the government promptly rewarded him by placing him in charge of a great institution for the study of infectious diseases, where the sera are made for the prophylactic and curative treatment of the most deadly diseases of the country, and where much original investigation is being conducted.

In England every little town has an officer of

health, appointed by the general government to guard its citizens against disease.

Lister, Pasteur, and Koch opened the door to scientific research; but long before their day, smallpox had been brought under control by the immortal Jenner. This loathsome disease would long ago have disappeared from the earth forever, but for the ignorant attacks of fanaticism. As has been truly said: "Nothing has tended more to retard the advance of science than the disposition in vulgar minds to vilify what they cannot comprehend."

Cholera and hydrophobia have been conquered by Pasteur, and Lister and Koch pointed the pathway to victory over the death dealing microbes of transmissible diseases. Through their instrumentality disease has become the slave rather than the master of mankind. No longer do diphtheria, tetanus, septicæmia, typhoid, cholera, puerperal sepsis, hospital gangrene, erysipelas, and wound infection hold the world in dread.

Notwithstanding that in 1904 the victims of bubonic plague in India numbered 1,022,000, and in the first six months of 1907 reached the appalling number of 1,060,000, a scientific campaign of prophylactic sanitation would soon stamp out the last vestige of its existence, were it not for the superstition of the natives which renders such a course impossible.

If scientific medicine has won these gigantic victories over disease, and in methods of its prevention, in the last twenty-five years, what wonders of discovery may not be divulged in the coming centuries. Let us for a moment see what results have recently been accomplished by an intelligent application of scientific medicine in the field of war. Its last and most noteworthy application was in the great Oriental conflict just concluded.

General Terauchi, Japanese minister of war, stated on November 23, 1905, in an address before the Red Cross Society of Japan, that "the total number of soldiers dispatched to the front during the war amounted to over 1,200,000, 80,000 of whom died, and 300,000 fell sick. Of this vast number only about 9,300 died from wounds, and 20,000 from sickness." This would leave the total from killed and battle casualties about 60,000; and from disease 20,000, or about one from sickness to three from casualties of war.

In April, 1906, a year after the last great battle had been fought, and when the totals were completed, Dr. Lynch (our military attaché in Japan during the war) in his report to our war department published the following official figures:

TABLE I.

Total in battle and from disease	88,888
Total from disease	20,000
Total died	80,000
Of these, less than one seen from battle casualties than from disease.	

The records of essential statistics for the past one hundred years as shown in the *Standard Tables* of Longman and elsewhere, are that four men have died from disease to one from battle. These figures of the Japanese army, therefore, constitute the most remarkable series ever published in

the history of wars. Almost similar figures have been unwarrantably contradicted by officers of the United States army, but the report of Major Lynch, our own medical attaché, just published with official records down to April, 1906, cannot be challenged.

In another table our military attaché states that in the Japanese war with China, in 1894, for every man who died from wounds 12.09 died from disease. In the war with Russia, ten years later, for every man who died from wounds, 0.46 died from disease, or one twenty-seventh as many.

In their titanic conflict the Japanese kept over 600,000 men in the field for over a year and a half; they fought some of the greatest battles of history, one of twelve days of incessant conflict, and another of sixteen days; skirmish fighting went on constantly during the entire period of hostility. In their campaigns the soldiers had their camp kettles, water boilers, blankets, and mosquito nets, and every man was protected by a net during the mosquito season. Their casualties have been nearly 40,000 in a single battle, or twice the entire number of soldiers we sent to Cuba, and yet, every man was promptly, carefully, and scientifically cared for. They fought through a country where insanitary conditions prevailed, often camping on the germ-infested sites of their enemies, and yet, by the incessant precautions of a numerically adequate medical corps, with power to enforce sanitation and hygiene, the army was enabled to make a health showing unheard of before in the annals of war.

In contrast to this picture let me for a moment invite your attention to the Puerto Rican expedition in that opera bouffe performance known as the Spanish-American war, for nowhere in history is there found a more illuminating instance, a graver lesson, or a more terrible warning, than is here portrayed. For our country is the "Mene, mene, tekel eupharsin," the handwriting on the wall, so easily decipherable that he who runs may read, and yet, in the glory of victory, and the enjoyment of prosperity, its lesson has passed unheeded.

The story of the expedition is brief. About 20,000 American troops landed in Puerto Rico, while the Spanish on the island numbered about 17,000. Several skirmishes occurred, in which, according to the surgeon general's report, three men were lost from the casualties of war. The object of the war, the breaking of the chains of Spanish despotism and spoliation, which for centuries had held a race in shameful moral serfdom, was soon accomplished, and the war—from the strictly military standpoint—was over. From our first arrival, the natives of the island welcomed our battalions with vivas of applause, strewing our advancing march with flowers, and their masses were prepared to joyfully second our efforts for their more complete emancipation.

That is the beautiful story that history presents. Lest we forget, as a nation, and lie supine in the easy content of this picture, let me invite your attention for a moment to a further study of the report of the surgeon general for that war. It states that although three men only fell from the casualties of battle during that entire campaign, 262, or nearly one hundred times as many, died from preventable

of hospital admissions nearly equaled the entire strength of the invading army, and that the camps of the army from one end of the island to the other, were pestiferous hotbeds of disease before they had been occupied a month, so that, had the bugle sounded for action, only a small percentage of the units would have been in a condition to respond to the call. Nor was this state of affairs confined to Puerto Rico. In the invading armies of the Philippines and Cuba the same conditions prevailed. The official figures, as shown on Table II, were furnished by the surgeon general of the army on the 10th day of October, 1905, and cover the vital statistics of the United States military expeditions for the year 1898.

TABLE II.

	Deaths from	
	Battle Casualties	Disease.
In the Philippine Islands .....	17	203
In Puerto Rico .....	3	262
In Cuba .....	273	567
In the U. S. home camps, etc., ..	..	2,649
Total deaths .....	293	3,681

or about one from casualties to fourteen from disease.

The report further shows that, while the average mean strength of the army enlisted for the Spanish war was about 170,000, the total number of admissions to the hospitals was on September 10, 1898, over 158,000, or 90 per cent. This in a war of less than three months' duration, and in which more than three-fourths of its members never left the camps of their native land. The Japanese army for the same period had about 4 per cent. hospital admissions, or one twenty-second as many.

The vast difference in the Japanese figures illustrates the value of a medical and sanitary department, properly equipped to enforce practical sanitation, dietary and conservative surgery.

The splendid achievements of scientific medicine in civil life in the prevention of disease should be even more effectually obtained in the army, where only healthy men are accepted, and vigorous outdoor camp life should keep its units, who are subject to strict military discipline, in perfect physical condition. Health alone, however, is no guarantee against the insidious attack of the silent foe that lingers in every camp and bivouac. It is this foe, as the records of wars for the past 200 years have proved, that is responsible for four times as many deaths as the guns of the enemy, to say nothing of the vast number temporarily invalidated or discharged as unfit for duty. It is this dreadful unnecessary sacrifice of life from preventable disease that constitutes the hell of war. In every great campaign an army faces two enemies. First, the armed force of the opposing foe with its various machines for human destruction, that is met at intervals in open battle; and, second, the hidden foe, always lurking in the camp, the spectre that gathers its victims while the soldier slumbers in barrack or bivouac—the far greater, silent foe, disease. Of these enemies the history of warfare for centuries has proved that in extended campaigns the first or open enemy kills 20 per cent. of the total mortality, while the second or silent enemy kills 80 per cent. In other words, out of every hundred men who

fall in war, twenty die from the casualties of battle, while eighty perish from disease, most of which is preventable.

TABLE III.  
Battle Casualties. Disease.

In the Russo-Turkish War the deaths were	20,000	80,000
In the six months of the Crimean campaign, as is asserted on eminent authority, the losses of the allied forces were	20,000	50,000
In our war with Mexico the proportion was	1 to 3	
In our civil war, about the same proportion	1 to 3	
In the French campaign in Madagascar, in 1894, of 14,000 sent to the front, twenty-nine were killed in action, and over 7,000 perished from preventable disease	20	7,000
In the Boer War in South Africa the English losses were about	1 to 10	
In our war with Spain fourteen lives were needlessly sacrificed to ignorance and incompetency for every one who died on the firing line or from the result of wounds, the figures being	203	3,081
In the Russo-Japanese War the figures were	58,887	27,168
or more than two from battle casualties to one from disease, thus reversing the records of all wars for the past 200 years.		

The difference between the martyr and the victim, between the soldier who falls on the field of honor and the man who meets a miserable death from preventable disease, for which his government is criminally responsible, is as wide as the celestial diameters. The one meets death compensated in the thought that his life is given in the protection of his country's flag and honor; the other is ignominiously forced to his grave through the neglect of the government that shamefully fails to protect the life he offered in its defense.

That the monstrous sacrifice of 80 per cent. is almost totally unnecessary has been abundantly proved in the records of the Japanese war, where 1,200,000 men were sent to the front, in a country notoriously unsanitary, and only 27,000 men died from disease, to 59,000 who fell in the legitimate line of duty on the field of honor. In the army of the United States in 1898, 2,649 picked soldiers died in three months, without leaving the country, in the pest camps of this, their own native land.

Unless an army maintains a thoroughly organized sanitary corps, prepared to fight germs and diseases in advance of the fighting forces, testing the water supplies, and avoiding the dangers from contagion and infection, the medical department might as well be abolished. If the Japanese had not realized this before their last war and taken measures to prevent disease, their army would never have won their brilliant and uninterrupted series of victories. If they had sustained the same ratio of mortality from sickness as in their war with China ten years before, their losses from disease alone in the Russian war would have nearly equaled the total of their entire losses from

all causes. This proves the value of the medical and sanitary corps, and illustrates its importance as a factor in the winning of the final issue.

The days of operative surgery on the field of battle or at the front passed with the discovery of asepsis and antisepsis. The Russo-Japanese war taught many lessons and destroyed many ideals in matters military as in matters surgical, where the hitherto accepted idea of the duties of the military surgeon was shown to be erroneous, where asepsis and antisepsis relegated the use of the scalpel to comparative obscurity and demonstrated conclusively that preservation of the army by prevention of disease is the surgeon's duty, first, last, and nearly all the time. In surgical technique, or in the after treatment of the wounded and sick, the Japanese taught the foreigner comparatively little, but in the field of sanitary science and dietetics they demonstrated, what had never been done before, viz., that preventable diseases *are* preventable and can be controlled; and that the great incubus of an army in the field, the presence of crowded hospitals and the large and expensive force necessary to equip and conduct them, can to a large extent be eliminated.

It is a sad reflection on our civilization that, while we regard as essential separate departments of State, Agriculture and War, in the executive cabinet at Washington, and issue bulletins for public distribution on swine cholera, cabbage culture, and crop reports, principally used by speculators, we deliberately ignore the safeguarding of our people from the horrors of infection and contagion. While the rest of the world has been making these splendid advances in the humanities, America—except in institutions fostered by private philanthropy—has stood in stolid indifference, doing little to stem the tide of destruction. We have allowed the wreckage and waste to go on, to cripple the energy with which we must challenge the future.

The relation of our federal government to public health has assumed some national importance, and if the efforts of the various medical societies of the country, the American Association for the Advancement of Science, the American Museum of Safety Devices, various insurance, accident and allied associations, are successful, it may receive a little more recognition. The paramount want is for a National Board of Health with a secretary in the cabinet of the President.

If this cannot be secured, a more liberal policy toward the National Bureau of Health, connected with the Marine Hospital Service, is much to be desired. Through an extension of the services of this organization the death rate of the country may be enormously decreased, possibly to the extent of one third to one half, and the general health of the community benefited by the eradication or amelioration of disease from preventable causes. But, as Dr. Welsh recently stated: "If the millions spent for the extermination of hog cholera during the last decade had been spent for the preservation of the public health, we should be far ahead of where we are to-day."

In the light of modern and sanitary science there is little excuse for the enormous losses by illness and death through typhoid, diphtheria, scarlet fever,

cholera infantum, and dysentery, all of which are preventable. The names of these diseases do not inspire the same terror as bubonic plague, yellow fever, cholera, and smallpox, but their victims are just as dead, and their bereaved are just as desolate. And these diseases might be stamped out quite as effectually as the others, with proper enforcement of sanitary precautions.

It is stated that the appointment of a Secretary of Health in the President's cabinet and the enforcement of regulations for the public health would interfere with the rights of States, but do the germs of cholera and yellow fever and tuberculosis and bubonic plague and measles respect State lines? And do streams polluted with cholera and typhoid bacilli cease to flow at State borders? Interstate commerce is not considered as an interference with State rights: then, why should interstate disease be so regarded?

Prior to the enactment of the pure food laws, which are now producing such beneficial results in the preservation of the public health, the same argument was advanced, but the passage of the act, instead of restricting the States, has induced them to enact similar or even more drastic laws in the same line; and no one objects—except the manufacturer or seller of adulterated products.

The estimation in which the authorities at Washington hold the only national institution we have for the preservation of the public health was recently evidenced by the efforts of a late member of the cabinet to abolish or restrict the work of the Marine Hospital Service on account of its expense. Many kinds of fools are required in the making of a world, but the American who would seriously advise the abolition of this last named institution combines in his single self the whole "fifty-seven varieties."

Disease is an enemy that causes more fatalities in a year than the combined armies of the world do in a century. As well might a general in an enemy's country abolish his pickets and outposts as for America with its extensive coastlines, its foreign commerce, and its enormous immigration to do without its Marine Hospital Service. I have seen these zealous guardians of our public health in almost every port with which we have commercial relations, always watchful lest contagious or infectious diseases might elude them and fasten on our native land, and with a fairly liberal personal experience and knowledge of our government in its various departments at home and abroad, I assert that the United States Public Health and Marine Hospital Service is the one department of which Americans have most reason to feel justly proud. Instead of restricting its powers, they should be amplified; instead of cutting down its appropriation, it should be increased. In no department of our government does the nation receive better returns on its investment, even through some of the mentally myopic politicians of the present administration fail to discover it.

And this argument applies with equal force to the medical department of the army. We go on expending nearly half a million dollars a day for the maintenance of our military schools, the education of men in the art of war, and the manufacture

of machines for human destruction, and in the plant necessary for putting these machines into execution, while in the study of the equally important subject of prevention of disease—the foe that kills four times as many as the enemy's bullets—is left comparatively unheeded. Every death from preventable disease is an insult to the intelligence of the age; if it occurs in an army, it becomes a governmental crime. The state deprives the soldier of his liberty, prescribes his hours of rest, his exercise, equipment, dress, diet, the locality in which he shall reside, and in the hour of danger expects him, if necessary, to lay down his life in defense of its honor. It should, therefore, give him the best sanitation and the best medical supervision that the science of the age can devise, be it German or Japanese—a fact of which congress will do well to take cognizance before it begins another war. For just as surely as the engineer who disregards the signals, or the train dispatcher who gives wrong orders, is legally responsible for the loss of human life in the wreck that follows, so congress, or the wretched system of the Medical Department of its army, is responsible for the thousands of soldiers' lives needlessly, criminally sacrificed—not on the glorious field of battle, but in diseased camps—from preventable causes. I believe that, if the Medical Department of the Porto Rican Expedition had been properly systematized with sufficient numbers, with supervisory control over the ration, and with power to enforce sanitary and hygienic regulations, the units of that army would have returned to their homes at the close of the campaign in better physical condition than when they had entered it, improved by their summer outing.

The Medical Department of our army, whose archaic system almost parallels that of Peking, while falling far below that of Patagonia (and I am familiar with both and speak advisedly), although unequal to cope with the exigencies of the Spanish campaign, is to-day, as the surgeon general states, relatively 50 per cent. worse off in numbers than at the close of the civil war in 1864, or at the termination of the Spanish-American campaign. The theory upon which it is founded, that the cure of disease rather than its prevention is its objective, still remains in vogue. Although men of brilliant attainments and individual merit are found on its staff, the deplorable system under which they are compelled to serve, and their lack of authority to enforce sanitation and hygiene, render the advisability of the continuance of the department under present conditions problematical. If it had been totally abolished during the Spanish-American war, and the army placed under the control of the Health Department of this city with such an officer as Colonel Waring, or its present incumbent, in charge, there would not have been such a disgraceful and infamous record. And why? Simply because that department would have had authority to enforce the orders respecting sanitation, diet, and hygiene, and would have assured the safety of the troops.

Under the present system, the same old medical regulations remain in vogue to all intents and purposes as prevailed before the microbic origin of disease was discovered and the key to sanitation found. So that, if another war were to be de-

clared next summer, our government would again convert the units of its army into hospital patients, and its veterans into pensioners.

The deplorable collapse of the Medical Department in the Spanish war resulted in the introduction into congress of a measure to increase its efficiency. The essential features of this bill are merely to increase the commissioned personnel of the medical corps, thereby abolishing the present system of employing contract surgeons, to afford an adequate flow of promotion and to establish a so called medical reserve corps, recruited from recent graduates, who, after examination, may be listed as available for service in time of war. No provision, however, is made for the instruction or training of these reserves.

As a measure of true reform the bill is hopelessly deficient in most essential features. It makes no provision for that most important of all adjuncts, an adequate sanitary department. One keen, up to date sanitarian, thoroughly skilled in hygienic, dietetic, and bacteriological knowledge and armed with the necessary authority to enforce sanitary measures, is worth a hundred so called surgeons to an army in the field, restricted, as they now are, by red tape and lack of authority in matters relating to their special department. No provision is made for an independent transport system, nor are medical officers given advisory authority over the Commissary Department or the soldiers' ration. A regiment may be suffering from diarrhoea or intestinal catarrh (and I have seen 90 per cent. of an entire command in this condition at one time), compelled to live on a diet of pork and canned beans and fermenting tomatoes until they became hospital cases. Up to this time, the medical officer has no authority to even order a rice diet, which would have prevented the men from becoming invalided. This was one of the principal causes that brought our army of 170,000 men in the Spanish war almost to its knees in the three months, and sent them home in the shrunken and shriveled condition well remembered by many here to-night.

Under the present system the line officer of the army is under no obligation to accept the recommendation of the medical officer as to the site or sanitation of a camp. Even in time of peace, he has no executive power to enforce sanitation, although he may be convinced that the health of every man is being jeopardized.

I quote from a letter received last week from a prominent medical officer in the Philippines; he says:

"Recently a post commander, without the knowledge of his medical officer, gave permission to a native to dump a stream on the reservation. The post had been kept free from mosquitoes and malaria only by the nearest vigilance. The medical officer, distressed personally, ethically, and by special sanitary reasons, but to no purpose. Almost every house soon became infected, one of the surgeons lost his wife, and these were our first cases. Finally a local post commander sent out the dump. The post was Camp Baraga."

One would suppose that every effort of the medical officers to maintain the health and vigor of the fighting units would be welcomed, and all the authority necessary to keep them so would be gladly accorded, by the officers of the line, so is the reality

of battle the men would be in the best physical condition. But this is not the case.

The officers of artillery, of cavalry, of infantry, the engineers, and of the signal service, can compel obedience to their orders, but the medical man, whose department fights the foe that has killed 80 per cent. in the majority of the great wars of history, cannot enforce an order, but can only make a recommendation, which the line officer can accept or reject at his discretion.

The bill ignores the pressing need for medical inspectors and contains no provision for the establishment of a department of pharmacy. This should have at its head a commissioned officer like the late Dr. C. C. Rice, of Bellevue, with commissioned subordinates, as is found in several of the best organized armies abroad. It should be charged with the purchase and distribution of all medical supplies, the sterilization and care of all surgical instruments, first aid materials, and the care of hospital records. This would relieve the medical officer of the complicated system of bookkeeping, invoicing, other similar work, that now makes him little more than a property clerk and decreases his value as a physician in ratio to the time he remains in service and wastes the valuable hours he should devote to the legitimate duties of his profession. The civil practitioner gave up the practice of toting his pills and powder when the scientific pharmacist appeared, but congress, apparently unaware of the advent of this adjunct to the medical art, still compels the army surgeon to peddle his shop wherever he goes, and holds him personally and financially responsible and liable for every item of equipment of the hospital and drug department of which he has charge, be it base, field, or post hospital.

Wherein is the fault of the present system? First and foremost, in the faulty organization of the Medical Department. The rank of surgeon general should be commensurate with the importance of the department of which he is the head. Under a proper system, this officer should be responsible only to a National Secretary of Health, who should be a cabinet officer, to the Secretary of War, or to the President, and there should be conferred upon him and his subordinates authority in all matters of sanitation and hygiene, except in the emergency of battle, when, of course, all authority should devolve on the officers of the line.

The importance of the medical, as compared with the other staff departments, has never been recognized or appreciated. Until it is realized that the most important function of the medical officer is in the prevention of disease rather than its cure, the old custom will prevail. To be efficient the medical officer must not only be a good physician, but a sanitarian, a bacteriologist, often a chemist as well as an administrator. Upon him devolves the duty of preventing disease, and his part in maintaining the effectiveness of the units makes him an important factor in the military establishment. His status is essentially military, not in the sense of fielding command, but as an integral part of an organization, complex in its composition, and whose different members should be so organized as to produce a harmonious and effective whole. Under the present

ing system, he is looked upon simply as a doctor, whose sole function is treating the sick and wounded—whose duties should be confined to the hospital, and whose recommendations should be submitted only when asked for.

In all the wars in which the United States have engaged, disease has been responsible for more than 70 per cent. of the mortality, more than one half of which could have easily been prevented, had the Medical Department been properly organized and equipped. Preventable disease more than wounds swells the pension lists. Statistics of the Pension Office prove that if this unnecessary loss had been avoided the saving in pensions alone would have paid the cost of the resulting war every twenty-five years. Aside from the sorrow of the homes made desolate, consider the economic value of the 70 per cent. of lives now uselessly sacrificed that might be saved as breadwinners in industrial pursuits.

The entire appropriation of the Medical Department for the fiscal year of 1898 was less than \$1,000,000; this was increased at the outbreak of hostilities with Spain by something over \$2,000,000. Then came the war. As a result of that almost bloodless conflict, the actual hostilities of which lasted only less than six weeks, we paid last year alone \$3,471,157 in pensions, with the further assurance of an annual increase for many years to come. The rolls of the Pension Office to-day bear the names of 24,000 pensioners, over 10,000 of whom are invalids and survivors of this war, and over 18,000 additional claims are now pending; although the total of the Cuban army of invasion was only 20,000 men. Last year we paid in pensions a total of \$146,000,000; this year the appropriation estimated for has increased to \$151,000,000. Are the fatalities of the past to be dismissed from the equation of the future? Instead of repeating our own blunders, why not emulate the successes of others? Possibly the recent action of the Executive in placing a medical officer in command of a hospital, although that hospital chanced to be afloat, may indicate a ray of hope.

It is far from certain, however, that congress alone is responsible for the deplorable system of our Medical Department. Why does not the surgeon general demand from congress all that is required to make the department really effective, even though the needed appropriation may be increased tenfold? Why does he not marshal his facts and figures and present them in illustration of the suicidal policy of allowing this great waste from preventable disease, thereby demonstrating the value of the medical man as a financial asset? Why does he not show that his department could pay for itself many times over in the annual saving of pensions, now resulting from its neglect—that statistics prove this loss amounts every twenty-five years to more than the cost of the war that caused it? Why does he not show the enormous increase in the efficiency of the army that would result from having fighting men instead of invalids in its ranks? Also the enormous economic value of the lives of the 70 per cent. now wasted that might be saved to their families as breadwinners instead of invalids and pensioners? Then let congress refuse his demand, if it dares assume that responsibility. The liberality and gener-

osity of our nation to its pensioners proves we are not always actuated by base or sordid motives; and if congress or the American people could be convinced of the necessity for these reforms, there would be little difficulty in obtaining their enactment.

Permit a moment's digression to narrate the personal experiences of a soldier, a member of the Association of Military Surgeons of the United States, which occurred within sight of the dome of the Capitol at Washington. He writes:

"My Dear Seaman:—On May 1, 1898, my regiment was sent from our home station to Homestead, L. I., for reorganization from a National Guard Regiment to a Regiment of Volunteers for service in the war with Spain. Our hospital corps of trained men was taken from us, as well as our medical supplies and instruments, and the regimental staff of three surgeons was reduced to one, with the rank and pay of a first lieutenant—rather short-handed for a full regiment of 1,333 men. Early in July I was detailed as Sanitary Inspector of the army corps to which we were attached, as typhoid fever was breaking out rapidly in every organization attached to the corps.

"My instructions were to inspect all camp sites, sinks, water supply, drainage, food, method of cooking, etc., and report in writing to the chief medical officer of the corps daily. I assumed the duties with great zeal, for sanitary problems had long been a favorite study, as I had been chief medical officer of my home city with its population of nearly 400,000 for six years.

"There was at that time a young man in my regiment, who formerly belonged to my hospital corps, a graduate of Cornell University, who had taken a postgraduate course in analytical chemistry and was well qualified for chemical and bacteriological work; also a private in a hospital corps detachment, encamped near us, who a few days before his enlistment had returned from Germany, where he had been a student and assistant in Koch's laboratory for four years. A valuable microscope was found in the first division of the hospital, which, as it was not used there, we were assured we could have.

"A list of the required material was prepared, with a probable cost of less than fifty dollars, and everything looked favorable for a successful inauguration of my plan. I accordingly drew up a communication to the chief medical officer of the corps, outlining the proposed work, showing how we could analyze suspected foods, and water, make the Widal test, blood counts, etc., and do such other work as would naturally present itself. I also informed him that all details had been arranged, and the only thing required to inaugurate the work at once was the proper orders from corps headquarters. It is impossible to express my surprise and disappointment when my plan was returned 'disapproved,' giving as the reason that the men whom I had selected to do the scientific work were not commissioned officers, but only enlisted men and that 'it would violate all the traditions of the army to do this work in this manner,' and that 'it was useless to establish a bacteriological laboratory in the field, as it could be of no practical benefit.' In vain I pleaded the urgent need of the hour, that the work could be done in my name, or even in the name of the chief medical officer, but all to no purpose. The plan for the scientific work was thoroughly 'sat down on.'

"I then respectfully asked what plan could be substituted, and was informed that application would be made for a detail of contract surgeons, especially qualified, who would aid in the work as outlined. My zeal, acquired as an old National Guard officer, subsided, and I plodded on in my work, looking on and seeing preventable disease sweeping away our soldier boys, and nothing, *absolutely nothing being done* to find the source of the infection or prevent its spread.

"The summer passed, the war was over, taps had been sounded over the graves of hundreds of brave boys who had never heard the hum of a hostile bullet, and early in September we were ordered to our home station to be mustered out.

"It was a beautiful Sunday morning, and the site where more than 20,000 men had been encamped was practically

deserted. I could hear the sound of the drums and bugles coming faintly through the woods, as the regiment marched to the railroad. I lingered at the site of the first division hospital with an ambulance, to bring the last of our sick away, when my orderly informed me that an officer wished to see me, and pointed to a man seated on a stump near by. I approached him, and was informed that he was a contract surgeon, sent by the department to report for bacteriological work. I told him that I was glad to see him, but that the war was over, that such of the soldiers who had not died of disease were now on their way home to be mustered out, and that I hoped he would stick to his post, so he would be ready for service when the next war broke out."

And there is nothing in the Medical Bill now before congress to keep that man on the stump, so he may be ready when the next war does come, or for his substitute in case he, too, may have joined the great majority before that time.

Is the great medical profession—a profession that in one of the bloodiest wars of history has contributed so largely in reducing the mortality of deaths from disease—to remain subservient to the dictates of the variety of judgment just cited, or is its department in our army to be reorganized upon rational lines, and its personnel empowered to enforce its mandates, so that the medical and moral rights of the soldier may be safeguarded and the country receive the benefit of his protection?

*Boast as we may* of our national patriotism and philanthropy, our altruism in freeing Cuba from the tyranny of Spain, and in elevating the status of that bunch of trouble, the Philippines; our foreign missions, and our great systems of charity at home; the cold, clammy fact remains that the sons of Nippon in their war with Russia treated their prisoners with far more humanity than our nation does its own soldiers.

In the great Oriental conflict just concluded, not once did the Muscovite win a victory, but from the Yalu to Mukden was driven from the field and often left to his victors the care of his sick, his wounded, and his dead. Sixty-seven thousand sick Russian prisoners were brought to Japan from Manchuria and nursed back to health. And to the eternal credit and glory of Japan let it be remembered that from the first aid dressing on the firing line, to the transport, the subsistence, the medical care, and the gentle nursing in her home hospitals, no difference was made between the treatment of her own soldiers and those of the enemy. Therefore, without minimizing the splendor of her victories on land or sea, at the Yalu, Port Arthur, Mukden, Shaho, Liaoang, or with Ego at Fushinoo, the fact remains that Japan's most splendid evolution and her greatest triumphs have been in the humanities of war. By careful preparation and organization, the use of simple, easily digested rations for her troops, and the application of practical sanitation by a fully equipped and empowered medical department, she almost obliterated infectious and preventable diseases from her army, and saved its units for the legitimate purposes of war, to wit, the smashing of the enemy in the field. She reduced the mortality in her own army by over 80 per cent, and treated her prisoners with a charity and consideration heretofore unheard of in the history of war, and established a standard in the humanities which the rest of the civilized world will do well to attain.

Let us hope that the day is not distant when the true value of the medical man in war will be appreciated in our own land and will be given the authority in his own sphere that will make it possible for our army in the day of emergency to equal, if not surpass, this splendid record. Braver men never served with the colors than the American soldiers, as we proved on both sides of the civil war, where many battles (in one of which, at Cold Harbor, ten thousand men fell in ten minutes) exceeding anything known in the Orient, and where it was conclusively proved that our soldier deserves every care and protection a generous government can bestow.

247 FIFTH AVENUE.

## ART AND SCIENCE AS APPLIED TO THE PRACTICE OF MEDICINE.\*

By L. HARRISON METTLER, A. M., M. D.,  
Chicago,

Associate Professor in Neurology, and Assistant Professor in Pathology,  
University of Illinois.

No sooner had I accepted the flattering invitation to deliver the address upon this the opening of the new college year, than I realized how large a mountain loomed up before me in the selection of a profitable and interesting theme. Before so general an audience as this a technical discourse would be quite out of place. In consonance with the occasion it seemed to me that I might speak of the *art* and the *science* of medicine, especially the principles underlying the broad conception of art and science, as applied to the *practice* of healing, and yet not be wholly unentertaining.

One thing I very promptly concluded not to do, namely, to retail the history of medicine "from Hippocrates down," as is so often and wearisomely done upon these occasions. The task would doubtless have been an easy and time saving one, with the assistance of a good encyclopedia and a rapid stenographer. I have listened to such addresses and have usually all but gone to sleep. As Bacon intimates, it was their easy writing that made the listening to them hard.

Another trite theme which arose in my mind and about which we are compelled to hear much to-day, is the wonderful progress of modern medicine. Tempting as such a theme is, I quickly discovered good and valid reasons for passing it by. The recent advances of medicine are being iterated and reiterated upon every possible relevant and irrelevant occasion. Vaccination, bacteria, serum therapy, anesthesia, and surgical technique have become, as subjects of medical discourse, as platitudinous as the state of the weather or the condition of the crops. In most instances the announcement of the title, modern advances of medicine, foretells for the audience a very humdrum address and a very poor speaker to deliver it. To present so self-evident a subject, with all its technicalities, attractively demands on the part of the orator a certain degree of brilliancy of style, and a versatility of ideas. Few medical speakers, however, can lay claim to such

distinction. The advances of medicine, as a matter of fact, are no greater than are the advances all along the line of science. This is the age of investigation and deep research, and medicine is merely keeping well in the van of progress. Most of my hearers will know in a few weeks more about these advances than I could begin to relate in the few moments at my disposal.

The goodness, charity, and self-sacrifice of the medical profession is another frequent theme that, in my judgment, is always ill timed and impertinent when handled before a lay audience. To put one's self on the back and to sound the bugle of one's own praise is, to say the least, indelicate and a bit humorous. It is childish and tends to make the medical profession a laughing stock in the eyes of the rest of the world. I have never been convinced that physicians, as a class, are more charitable or kindly disposed to their fellow creatures than is any other class of worthy and reputable citizens. The latter, to be sure, have not the advantage that the physicians have in exhibiting *personally* their beneficence and good works; but with what means they do possess, money and sympathy, I think they do quite as much charitable work as the physicians do. Much of the so called charity in our profession, be it said to our shame, is for personal advertisement and self aggrandizement. We must guard here against adding hypocrisy to the unpleasant charge of thinking too well of ourselves. It is pointed out that medical men give their services freely to the hospitals and dispensaries. True, they do give their services without salary or direct monetary return; but can it be candidly said that they give those services as a self sacrifice, without any hope of ultimate benefit? I think not; and I am entitled to think so, because there is abundant available proof that they do not. Let us be frank and have the courage of our convictions, declaring that in, as well as out of, the profession the laborer is worthy of his hire. Ability, competition, supply, and demand rule here as elsewhere; and as to charity and philanthropy, be it said, the medical profession ranks second to no other. It does what it can, in the best way that it can, to alleviate the sorrows and sufferings of the world. The spirit of charity is something that belongs to the man whether he be a medical man or not. It is not an exclusive endowment, nor is its exercise a special privilege, conferred upon him by a medical diploma. Therefore I will have nothing to say upon the philanthropic spirit of medicine. I prefer, if such a spirit really exists to any superior degree in my profession, to let my neighbor, the nonmedical man, speak of that.

And finally I know how pleased you will be when I tell you that I do not purpose preaching a sermon to the students in this audience. There is nothing so cheap and uncalled for, it seems to me, as the average talk upon morality and good behavior often doled out at the opening of the medical schools. A medical man is rarely a good preacher by heredity, training, or past mode of life; and for him to drop into the giving of monotonous, singsong platitudes to a body of men who have reached years of discretion and who are about as experienced in life as he himself is, bespeaks either laziness, mental vacuity,

or an coming old age. Medical students are as alert, attentive, and eager for knowledge as any body of men I know of. I am satisfied that a lecturer who finds it necessary in his class room to be incessantly admonishing his hearers, is himself the source of the trouble, his manner of presenting his subject being, in all probability, stale, stupid, and lacking in originality. *Science is never uninteresting.* It needs no help from sermons, admonitions, and moral discourses to make it attractive. It is the labored, flat, inartistic, inconsequential way in which science is often doled out that makes it seem repulsive. The dry rehearsal of mere facts and phenomena is neither brilliant nor illuminating. It is more often not even scientific, though such is what it usually is supposed to be in the class room. Explanation, correlation, and illustration are always fascinating, and when properly presented in conjunction with the description of facts and phenomena will constitute the attractive element in the scientific lecture. Of this I will have more to say anon.

The terms *medical art* and *medical science* are ever upon our lips. They stand for two separate and distinct ideas. It is my desire to emphasize the distinction so as to discover, if possible, how near to and how remote from we stand to-day, in actual medical practice, the fundamental conceptions of art and of science.

The *Century Dictionary* declares that an *art* is "the combination or modification of things to adapt them to a given end; the employment of given means to effect a purpose." Obviously, then, the term involves the idea of skill and dexterity.

From the same authority we learn that *science* is "knowledge; comprehension, or understanding of facts or principles; knowledge gained by systematic observation, experiment, and reasoning; knowledge coordinated, arranged, and systematized." Note that this definition does not say anything about facts and phenomena when merely described as being scientific. It affirms that the comprehension and understanding of the facts and underlying principles constitute science.

The ultimate aim of both art and science is the realization of truth.

Wherein they differ is the manner of arriving at the truth. Science accomplishes it by means of analysis and criticism; art by means of synthesis and reconstruction. As Karslake has well said, "Science and art may be said to be investigations of truth, but science inquires for the sake of knowledge, art for the sake of production."

There is a partial overlapping, of course, of both art and science, just as there is in all the complex forms of human activity. There is some art or skill required in the analyses and criticisms of science, and there is much science lurking behind all forms of art expression. The truth aimed at in the art and science of medicine is health. The art endeavors to reveal that truth in all its physiological beauty and perfection by employing the most effective means for the restoration and maintenance of health. The science searches for that truth by uncovering the hidden laws and principles upon which health is founded. Not wrong are we, therefore, when we speak of the art of medicine as distinguished from the science. We are wrong only when we fail to give due recognition

to both the art and the science, and like the quacks practise the art without the science, or, like certain narrow minded laboratory men, emphasize the science to the belittling of the value of the art.

Let me ask, for a few moments, your consideration of certain characteristics which belong to the practice of an art; and then I will request you to apply those characteristics to the practice of medicine as we see it about us to-day. In doing the latter you will remark many things that may prove suggestive and profitable to yourselves.

Art, being synthetic and constructive, the dominant element in the cultivation of it must necessarily be the personality of the artist. In direct ratio with the natural endowments of a given individual will his artistic efforts be. The ability may rise to the level of talent, even to that of genius. It is something that cannot be acquired, though by cleverness it may be somewhat remotely and unevenly simulated. It depends upon some mysterious and inherent mode of brain action, about which we as yet know absolutely nothing. It is a unique, special, and congenital faculty. It is always the cause of much envy, but it cannot ever be directly acquired any more than can a desired increase of height. Moreover, it is seldom, if ever, understood by those who have it not. An old lady once said to Turner, after gazing at one of his most gorgeous paintings in the British Museum: "Mr. Turner, why do you use such brilliant coloring in your pictures? I never see such reds and blues and greens as that in nature." "Don't you wish you did, madam?" was all the reply he vouchsafed her. Of the things that the artistic mind is capable, most of us can only wish that ours were capable of them too. In medicine a man sometimes legitimately wins a large practice, obtains a surprising series of cures, or makes a most happy run of correct diagnoses. How he does it we cannot tell. Like the artist, he cannot always tell himself, for of all men the genuine artist is the poorest of critics and the least helpful of advisers. His mental mechanism seems to work instinctively, not through the slow processes of logic and rational deduction. When Sir Joshua Reynolds declared he mixed his colors with brains, he meant the brains of Reynolds and not the brains of anybody else. No mere knowledge of rules will furnish one with an artist's mind. Nobody, perhaps, knew the secrets of the art of painting better than did Ruskin and Hamerton; yet the pictures of these two great critics were mere daubs beside those of Turner and Millet. A nobleman once asked Guido who was the model he sketched his beautiful Madonnas from. The painter, placing his color mixer, a huge, ugly, and ungainly man, in an appropriate pose, said to his visitor, "Count, that is my model," while at the same time he went on drawing the outlines of a most exquisite female figure.

So instinctive are the workings of the mind of the true artist, and so unknown are the laws of its mechanism, that the possessor of it is times and times again veritable law unto himself. Beethoven was once sharply criticised for breaking an established rule of harmony. In a burst of anger he exclaimed: "I make my own rules!" Thereafter the composer's alleged blunder became an accepted musical form. Little minds, and those not of the true artistic type, often

ape this apparent lawlessness of genius, just as the gilded youth once imitated the collars of Lord Byron. An imitation, however, is always detectable, because it is always more or less lawless and inappropriate. Beethoven did not make his own rules of harmony, as he angrily exclaimed; but, by following instinctively his own transcendent genius, he merely revealed the principles of musical beauty which up to that time had not been portrayed by any one.

The dominance of the personality in the concept art precludes all possibility of simple imitation being in any sense true art. Photography is not an art any more than is the working of a turning lathe. The models from which both the camera and the turning lathe began making their copies may, in some way, have revealed the personality of the artist; but then it was the selection and the arrangement of the models, not the making of reproductions, that constituted the art. As Emerson puts it, speaking of trade and every mechanical craft, "there is in each of these works an act of invention, an intellectual step, or short series of steps, taken; that act or step is the spiritual act; all the rest is mere repetition of the same a thousand times." Imitators are never true artists. As soon, however, as they inject the slightest degree of their own personality into their work, that work at once becomes artistic in the broadest sense. Art, therefore, modifies, instead of imitating, everything that it touches. The modification indicates something that belongs *sui generis* to the artist. "Art has the advantage of nature," says Lubbock, "in so far as it introduces a human element, which is in some respects superior even to nature." A Webster dictionary can never be regarded as a work of art; a Scott novel can never be regarded as anything else. A Beethoven adagio is beyond all imitation, whereas a Richter exercise in counterpoint may be duplicated innumerable times. Wonderful copyists are the Chinese, but their art is of a very low grade. The accuracy and finish of Boileau's *L'art poétique* does not make it a work of art; the personality of the poet is utterly wanting in it. Mere imitation and accuracy can never alone result in the practice of the art of medicine. They will reach only as far as externalities and nonessentials. They are the cause of much of the quackery both in and out of the profession.

In this age there is much multiplication of everything, books, railroads, machinery, tall buildings, shirts, and cigars; but in the midst of it all there is comparatively very little genuine art. Lubbock says that "in art two and two do not make four, and no number of little things will make a great one." A physician's practice may be large and yet be as devoid of the art of medicine as a fourteen story skyscraper is of the art of architecture. Diagnosis and therapeutics, however elaborately practised, do not alone constitute the art of medicine. The management of a single case, revealing a unique degree of appropriate intelligence, stands more for the practical art of medicine than do a hundred cases merely observed and haphazardly prescribed for. A large clientèle, like a multitude of bales of cotton, may be very profitable, and in a commercial sense may be very beautiful and rich. In no way, however, does it constitute the art of medicine.

trary, it is more likely to bespeak inferiority; for increase of quantity is usually synonymous with diminution of elegance and completeness. In the art of medicine "two and two do not make four and no number of little things will make a great one.

Once a nobleman asked Bismarck to place his son in some high office, urging that the boy was highly educated and well fitted for the position, since he could converse in a dozen different languages. The great chancellor knitted his brow and, after reflecting a few moments, replied to the anxious father that, in his opinion, his son would make a splendid headwaiter in a cosmopolitan hotel.

Dominant as is the personality of the artist in all of his work, that personality is further distinguished by being uniquely initiative, creative, enthusiastic, and positive, rather than conservative, destructive, calculating and negative. The artistic temperament is ever driving its possessor into doing something, however great or small that something may be. It leaves him little time or inclination to merely criticise and analyze what already exists. This creative faculty is far from being a common one. It provokes astonishment in those who, having it not, behold its strange and unwonted revelations. For this reason it generally confers upon its owner the leadership among his fellows. Its very wonder working keeps alive interest and enthusiasm. It is always positive, believing that affirmation and construction, however slight, are nobler than mere denial and annihilation. It holds that Shelley's Ode to the Skylark is a greater work than are a thousand tomes of descriptive ornithology. It insists that the Greek Slave of Powers transcends a whole museum of human anatomy. It points out that the six hundred and twenty books of Varro, the most learned of Romans, are lost, while mere fragments of the poems of Sappho are still treasured beyond all price. Man himself being the most wonderful of creations, it is the exclusion of his personality from science that gives the supremacy to art. And therefore Thoreau exclaims: "My friends mistake when they communicate facts to me with so much pains. Their presence, even their exaggerations and loose statements, are equally good facts for me."

Novelty constitutes a prominent element of art; hence art is always hard to criticise. Very rightly do we say of a work of art that it is good or bad according to one's taste. Being a creation, it is wholly new and portrays for the first time the artist's taste, which may or may not correspond with ours. Hottentot music is not art to us; and much less would our music, I fancy, be art to the African savage. Works of art are always unique and distinctive.

Art is always most happily cultivated in an artistic environment. That is the reason why artists live, singly or in little groups, so much apart from the world. In the light of the importance of environment, it is not difficult to understand why Greece and Italy are the home of art, while Guiana and Kamschatka are not. The family life of the Bachs was enough in itself almost to turn out a remarkable group of musicians. The keeping together of the Lake poets gave a distinctive touch to their works. The Preraphaelites showed plainly their close intimacy with one another. The Elizabethan

age of literature and the New England coterie of authors owed not a little of their distinction and individuality to the times and local associations. A physician who yearns to excel in the art of medicine dare not live apart and away from the influences that tend toward the best and highest in his calling. The doctor must dwell in his books, his medical societies, his intellectual companionships. He must absorb the best they have to afford him, yield placidly to their highest influences, and feed his mind upon them every day. But alas! how often the rich literature of medicine is neglected for cards and club gossip! What arenas for petty squabbles and cheap politics are some of our medical societies! What miserable little jealousies are allowed to separate men who, as professed practitioners of a noble art, could be so helpful and inspiring to one another! Such conditions always betray a lamentable want of the proper temperament and environment. It indicates a raw commercial atmosphere; a dull, primitive level of barter and sale; not perhaps necessarily wrong in itself, but oh! so wearisomely monotonous, cheap, and commonplace. Babies and animals know very little beyond the desire and struggle for nutriment, and in the exercise of their incessant cunning to obtain it they are less despicable than certain adults who work the medical societies, journals and hospitals solely as a means of advertisement, whereby they may earn an extra pot of potage. Such individuals wither and blight the art of medicine.

Another important fact to be noted in regard to the practice of an art is the laboriousness of it. Because the artistic temperament is a natural faculty the world has usually fancied that its exercise required no special effort. No greater mistake was ever made. Indeed genius, which is generally deemed the exemplar of the highest art, is sometimes defined as merely the capacity for taking infinite pains. I have heard it stated, upon good authority, that Paderewski repeated uninterruptedly a certain cadenza, during one of his practising periods, some seven hundred and odd times. "Art is no recreation," says Ruskin; "it cannot be learned at spare moments nor pursued when we have nothing better to do." As Bryant sang:

"Deem not the framing of an immortal lay

The idle pastime of a summer's day."

Yet many students and practitioners play at this most difficult and exacting art of medicine.

Ruskin further tells us to "remember always that there are two characters in which all greatness of art consists—first, the earnest and intense seizing of natural facts; then the ordering those facts by the strength of human intellect so as to make them, for all who look upon them, to the utmost serviceable, memorable, and beautiful." There are laws and principles—great truths, if you please—that underlie all art. Painting without a knowledge of color, drawing, and perspective is Chinese art. Music devoid of harmony and rhythm is not even, as Johnson defined music, "the least objectionable form of noise."

And now this brings me to the second part of my discourse, the *science of medicine*. As I have just intimated, the art of medicine is a farce unless it is guided by certain truths and based upon certain

established principles. These, however, constitute the science of medicine.

No term is more misused at the present time than this term science. Practically nowadays every sort of silly routine, every systematic form of human activity, is denominated a science. There is the science of pedestrianism and pugilism. Cookery and haberdashery are said to be sciences. There is a Christian science, and a scientific Christianity. Everything, everything, from the mowing of the lawn to the sleeping in one's bed at night is taught scientifically these days *ad nauseam ad infinitum*. Seriously, however, science is knowledge, and stands only for the correlation of phenomena whereby causative factors and underlying laws are discovered. The mere application of principles for the accomplishment of certain ends is no more science, in the true sense of the word, than are the mere observation and description of unexplained isolated phenomena. What is there scientific in eating peanuts for sixty days to prove that life in a certain individual can be sustained on such a diet? Such a performance and many like it repeated in our laboratories is about as scientific as the eating of a green apple by little Willie to prove that a painless existence is, after all, the happiest. Much of what is dignified as modern science is a roaring farce. It is nothing more, to say the most of it, than individual experience, and ranks with such knowledge as that corns on one's toes are disagreeable and that wintry blasts are apt to be cold. Phenomena and their mere observation are not, as a rule, very illuminating. They need some explanation, some generalization, possibly even some theory or hypothesis to raise them to the dignity of scientific facts. When the Church of Rome forced Galileo to make his famous retraction in regard to the movements of the heavenly bodies, it based its authority upon simple observation and ecclesiastical dogma. It knew nothing of, and even denied, the generalizations and hypotheses that Galileo had worked out. It was satisfied that the earth stood still and all other bodies revolved around it, because such was the testimony of every man of common sense who had eyes to see. The inevitable soon occurred. The Church was shown to be puerile in its thinking, Galileo scientific. Tycho Brahe's long records in regard to the positions of the celestial spheres did not elevate astronomy to the plane of a science; only the generalizing of Kepler, from those long and laborious observations did that. Millions of people have watched apples fall. It was Sir Isaac Newton's enunciation of the hypothetical law of gravitation, however, that raised the phenomenon and its observation to a position of scientific interest. Medieval alchemy was the poor culmination of the mere observation of certain phenomena. The science of chemistry was born when Dalton and others developed the atomic theory and related explanatory hypotheses.

There are medical men to-day who publish form and detailed reports of cases which they have observed. There are pathologists who describe and depict most elaborately what they behold under the microscope. There are physiologists who construct most ingenious apparatuses for recording cardiographic tracings. There are psychiatrists who

cover reams of paper with mere repetitions descriptive of the actions of asylum inmates. The labors of every one of these men have, of course, a certain value. An infant's observation of the moon has also value. The worth of both sets of observations falls short of being scientific, until they are properly correlated and in some way explained. For the scientific elucidation of phenomena the inductive method of Bacon, when employed alone, is as faulty as the deductive method of Aristotle. Isolated and unexplained data stand for mere phenomena. Phenomena as such represent mere sensory reaction on the part of the observer. The observation is the only thing about them that can be truthfully denominated a fact. Observation *per se* is always liable to error by reason of the observer's personal equation and sensory instability. Such error can only be eliminated by the correlation of observations, by their rigid comparison and contrast, and this involves and results in the employment of imagination, reason, and judgment.

Facts, even most so called scientific facts, are not entirely beyond the charge of being mere descriptions of our sense organs. The word fact, so revered by the great untrained mind of man, is not synonymous with truth. It means when so used by this great untrained mind of man merely sense observation or phenomenon. It becomes synonymous with truth only when it stands for some correlated phenomenon, some principle, some law discovered amongst a mass of sense observations. Redness is a fact to common sense, but it is not a truth. The same is to be said of sound. The truth in both instances is a particular form of movement, vibration. All knowledge is more or less relative, and a commonly called fact is the most relative thing of all. This is the reason why the advance of human knowledge has been borne along on "facts" that have almost invariably been found later on to be in need of different interpretation. The newer interpretations have arisen out of the discovery of the causes and underlying principles. The latter and not the so called facts then established the science.

This confounding real knowledge with the mere observation of phenomena explains many curious things in the history of science. It renders intelligible, for instance, the fact that science had its origin in ancient mythology. It accounts for its long struggle through mediæval witchcraft, necromancy, and astrology. It affords a *raison d'être* for the modern camp following of science, consisting of the half informed, semireligious, queer folk.

The origin of life in the sea, typified in the ocean born Venus; the panorama of the dawn so poetically sung in the story of Orpheus and Eurydice; the growing and moaning of the forests, attributed to the Dryads; the unceasing flowing of the brooks, urged on by the sportive nymphs; the wanderings of the moon among the stars as Demeter chasing the deer; and the intense brilliancy and creativeness of the sun, depicted under the form of the glorious Apollo, are not more fantastic than are some of the half-scientific, supernatural explanations offered nowadays for phenomena which require rational, not mysterious and supernatural, explanations. Dreams, revelations, telepathy, spiritualism,

relation, systematization, something far more than the mere accumulation of statistics. Science is knowledge. As Stanislaus says, "Science, when well digested, is nothing but good sense and reason." Mere observation and the accumulation of statistics do not make very elaborate calls upon either good sense or reason. Oliver Wendell Holmes gently satirizes these mere observing, statistical men when he says, "Science is a first rate piece of furniture for a man's upper chamber, if he has common sense on the ground floor. But if a man hasn't got plenty of good common sense, the more science he has, the worse for his patient." As Stern intimates, this form of learning, namely, statistical observation, is the dictionary, whereas sense is the grammar of science. Anybody with drudgeliike persistency can compile a dictionary, but to create or evolve a grammar calls for a rare and superior type of intellect. This type of intellect is not more common in the medical profession than it is in any other class of men. Here, however, we witness much passing under the name of science that is nothing but multiplication of the simplest sort of observation. Long case reports full of insignificant detail and repetition, minute pathological descriptions, curious physiological experiments, and elaborate rehearsals of well known clinical phenomena are doubtless of some value, even as a child's description of an elephant, that it may have seen in one of its straying spells from home, is of value; but unless some explanation or correlation is vouchsafed at the same time, some hypothetical yet well deduced law affirmed for future approval or disapproval, the value is small. An eminent pathologist showed me some years ago a brain which he had just received, and which he said was histologically a most extraordinary specimen. His tone of dejection I shall never forget when he further said that the specimen was all but practically worthless for scientific purposes because the clinician who had sent it to him had not attempted to study the case in all of its symptomatic relationships. The clinical report could not be correlated with the pathological findings, and hence, though much time had been expended in mere observation in both, no real scientific knowledge was forthcoming. The lament of Thoreau voiced itself thus: "I should say that the most prominent scientific men of our country, and perhaps of this age, are either serving the arts and not pure science, or are performing faithful but quite subordinate labors in particular departments."

We are living in the age of science. Future historians will devote a chapter to it, as they do now to the Greek age of art, the Roman age of law and order, the ages of feudalism and of chivalry, of the Renaissance and reformation, of discovery and political revolution. The age of our time, the age it is to live in!—is treading close upon the footsteps of the Creator. It is learning the secrets of His handiwork. It is discovering the forces that He has employed in building the world, in the universe, through boundless space, in fixing the rocks and oceans and oceans in their appointed places, in developing life through all its varied forms up to the divine culmination, the human intellect. Wonderful are the revelations that daily open up before us. We marvel at our old ignorance and superstitions. We await in awe the newer light yet to be shed upon the

So rapid and startling are these scientific revelations and so wizardlike are their practical applications for our personal comfort, that, like little children upon a Christmas morning, we are excited, confused, and all but paralyzed with ecstasy. Some of us have utterly lost our heads and grown irreverent and egotistical. Others among us seem to crouch with fear and fly to newer and more ridiculous forms of superstition. Nearly all of us have become prone to laugh at authority and to stand with hands folded, obstinate and expectant, if not actually sceptical.

This is a transition age we live in. We have left darkness behind us, with yet many hidden mysteries in front of us. Now, if ever, do we need clear brains and reverent spirits. In an age like this men are wont always to go to extremes. Stunned by the magnitude of its discoveries, they seek relief in petty detail or prattle flippantly about that which is still unknown. Why do we not find the greatest thinkers of the world of art and literature among us today? Because of our engrossment in the petty details of research. Indeed, this age has been facetiously called "the age of the little"—the little story, the little piece of music, the little genre painting, the little bacteria. While this not strictly true, it is true that there is much overemphasis of the little at the present time. Our apparent bigness, as instanced in our railroads, office buildings, financial transactions, and commercial corporations, is largely a matter of mere reduplication. Hence one feels at times like Berlioz, I think it was, who, after leaving one of Chopin's most exquisitely soft and delicate piano recitals, shouted so loudly upon the street that one of his companions asked him if the music had, indeed, made him crazy. "No," he replied, "I am not crazy, but I have been listening to so much pianissimo that now I want a little fortissimo!"

This tendency to excess of detail, with bigness consisting of mere reduplication, leads, in this age, to the dangerous magnification of means with corresponding blindness to the end. As a recent writer in the *Atlantic Monthly* pointed out, the dominant fault of the average man is the hopeless losing of himself in the means. He allows himself to become immersed in it like a fly in a spider's web. As the writer shows, this is preeminently noticeable in the financial and commercial worlds. Money making has become the end here, though every child knows that money is absolutely useless except for what it brings or as a means to an end. Many are to-day entranced with machinery, telescopes, microscopes, automobiles, and the other means whereby we are striving to climb to knowledge and happiness. As this entanglement in the means results in the money world in greed, strife, discontent, irreverence, and even criminality, so in the world of intellectual achievement it results in a similar state of affairs, in the same kind of blindness, in the same kind of hypocrisy. That which is not knowledge is fawningly or fraudulently palmed off as knowledge. Truly, as the writer says, "the world is full of men who are like lizards in their phials, science has done for him what he could not do for himself. He has been engulfed in the little and lost in admiration of the means. He has been so busy with the means that he claimed that he could never learn anything from the fields and trees, or like Samuel Johnson when he announced that 'having seen a great deal, you find

seen them all." If ever an age were in need of well balanced idealists, men of broad liberal minds, men who can distinguish mere agency from finality, it is this age. Very recently I read a long and exhaustive article, published in two installments, full of petty details of description and illustration, at the conclusion of which the distinguished authors stated that what they had been trying to demonstrate was still a matter of complete uncertainty. All that paper and ink for that vapid conclusion! It doubtless looked and sounded very scientific. An investigator, however, less entranced with mere agencies, would have saved his readers' time and eyesight by stating that he had no information to give upon the subject in question. Let it be repeated, *science is knowledge*, not mere statistical accumulations. The greatness of Goethe's Faust lies partly in the fact that it represents a protest against the belittling, detailed science which is devoid of idealism and intellectual breadth. The present age is beginning to weary of scientific coxcombs, men who arrogate to themselves the name of scientists but who never add a single grain to the sum total of human knowledge. It wants men who can *interpret* and *explain*, not merely observe, the phenomena of the world about us. It has small rewards for the mere compilers of the commonplace, the laborious collectors of dry statistical husks and irrelevant accumulations.

In conclusion, then, let it be clearly recognized that there is an *art* and there is a *science* of medicine. Those who practise medicine as a fine art and as a real science are far from being numerous. In fact, they constitute quite a minority in the profession. There is still abundance of room for him who sincerely desires to develop this noble art and wonderful science. What Lincoln said about fooling all the people all the time is as true here as elsewhere, depend upon it. An honest and earnest effort to attain that which is the best, the highest, and the truest, even in medicine, never goes long unrecognized and unrewarded. I would merely add as my final word to you, young men, that you be true to yourselves and to your divine privilege of manhood. Live up to the full stature of your endowments and make for the advancement of your chosen profession along the lines of true art and science, as I have endeavored, all too briefly, to indicate them to you.

100 STATE STREET.

#### THE MANAGEMENT AND TREATMENT OF TUBERCULOSIS IN INFANTS AND CHILDREN.

By JOHN LOVETT MORSE, A. M., M. D.,  
Boston.

Professor of the Hospital Medical School, and Visiting Physician, Floating Hospital.

The general principles of the management and treatment of tuberculosis in early life are, of course, the same as in later life. They have to be somewhat modified in their application, however, because of the manner in which tuberculosis manifests itself in early life and because of the different way in which children bear exposure and react to climatic conditions.

The chief characteristics of tuberculosis in infancy are its malignancy and its tendency to dissemination.

The restriction of tuberculosis to a single organ and the involvement of the lungs, as it occurs in later childhood and in adult life, are very unusual. The fatality of tuberculosis at this age is so great, therefore, that little can be hoped for any form of treatment. In young children the tendency to localization is greater. The bones and serous membranes are much more frequently involved than the viscera, and there is also a decided predilection for the lymphatic system. In older children pulmonary lesions are more common, the frequency increasing directly with the age, but they are comparatively rare before puberty. The course of pulmonary tuberculosis at this age is more rapidly progressive than later. At puberty the lesions, course and treatment are essentially the same as in adults.

Children are more rapidly enervated by warm, moist climates than are adults. They are not, as a rule, robust enough to bear extremely cold climates, although there are exceptions. They are much less able than adults to bear exposure, and great care must be taken in "hardening" them, especially if they are young and delicate.

It is, as a rule, much easier to carry out proper treatment with children than with adults. They do not have to consider their own livelihood or that of others; they are not wage earners; nothing depends on them. Consequently they can devote their whole time to their treatment. Their mental attitude is better; they do not worry about themselves or others. They are more amenable to treatment and almost always make good patients. It is, however, rather more difficult to get them to sleep out alone as they are often afraid. They require, on the other hand, more attention and amusement. They must have manual and physical employment; they must be instructed and educated. It is easier to take care of them because of their small size. They can be carried about more easily; they require less room. A small balcony, for example, will do for a child, while a large one may have to be built for an adult.

They accommodate themselves to institutional life much better than do adults. They are almost never homesick after the first few days. They are not constantly wishing to get out and go to work. They are not anxious about their own future or that of their families. They are usually very happy with the other children and take to the life naturally. Discipline is much easier with them than with adults.

For practical purposes, tuberculosis in children may be divided into two classes; surgical, including "scrofulosis" and "lymphatism," and visceral.

Experience with children suffering from surgical tuberculosis in the sanatoria abroad shows that, on the whole, they do better at the seashore than inland, and that they do better at the seashore if the climate is temperate rather than cold or warm. Our experience at the Convalescent Home of the Children's Hospital, in Boston, however, shows that they may do well inland and in a cold climate. Experience also shows that in order to obtain a cure, a stay of at least a year is necessary, and that a few weeks or months is entirely insufficient. Children of the erithritic type, that is, the delicate, slender, and neurotic, usually do better, at any rate in the beginning, inland in comparatively mild climates. It is important not to overdo exercise with this class

of children. Children of the "torpid" type, that is, the heavy, coarse and phlegmatic, do better at the seashore than inland, and in comparatively cold climates. They bear "hardening" well and can take a good deal of exercise. If amyloid or kidney disease develops, both classes do much better in a warm and dry climate.

This country is far behind many of the European countries in the establishment of sanatoria for surgical tuberculosis, whether for the rich or poor. New York, as you know, has begun to do something during the last three years. Boston has for some years been doing a little at the Convalescent Home of the Children's Hospital in Wellesley. It is probable that other cities are also beginning to take steps in this direction. What is being done, however, is absolutely insufficient. Very few children are being taken care of, and these are not kept nearly long enough. Much more is being done in the way of excursions, country weeks, and so on. These are merely makeshifts, however, and while well enough as far as they go, are absolutely inadequate to give any permanent results.

Tuberculous peritonitis, while really a form of visceral tuberculosis, is as regards its climatic treatment and management essentially a form of surgical tuberculosis.

While visceral tuberculosis in adult life means to all intents and purposes pulmonary tuberculosis, in the vast majority of instances uncomplicated, this is not the case in early childhood. At this age pulmonary tuberculosis is usually not a local disease but part of a more or less generalized tuberculosis. The younger the child, the truer this is. The prognosis of pulmonary tuberculosis in early life is therefore much worse than in later life, and much less is to be expected from climatic treatment. In young children the disease is usually too far advanced when recognized to warrant sending them away from home, as at this time they belong, as a rule, in the incurable class. Children with pulmonary tuberculosis are even less able to bear extreme cold than are those with surgical tuberculosis, and withstand "hardening" and exposure very poorly.

The dietetic treatment of tuberculosis in early life is essentially the same as in adult life. Milk and eggs are at this age also the most valuable articles of food. Much greater skill is required, however, to feed a child, especially a young child, properly without upsetting its digestion, than an adult.

The drug treatment of tuberculosis in childhood is purely tonic and symptomatic. The susceptibility to opium in any form at this age must be remembered.

The various forms of tuberculin have been used much less in children than in adults, and there are comparatively few statistics on this point. I know nothing about it from my own experience. There seems no reason, however, why equally good results should not be obtained in children as in adults, if allowance is made for the greater severity of the disease at this age and the greater tendency to dissemination.

Thus far only children with tuberculosis have been mentioned. Two other classes ought, however, to be considered. These are the healthy children of tuberculous parents, and children with latent

tuberculosis or those who are predisposed to tuberculosis by the presence of other diseases or their parentage.

The children of tuberculous parents should, if possible, be sent away from home. The Society for the Protection of Children against Tuberculosis in France, established by Grancher, is adopting the proper methods for these children. When they cannot be sent away from home much can be done by regulation of their life and by guarding them against infection from the parents.

Children suffering from latent tuberculosis or for any reason predisposed to it should, if possible, be given proper climatic treatment or sent to sanatoria. If this is not possible, every attention should be paid to their hygiene, food, rest, and care. The children of the poorer classes should be sent to fresh air schools, and given the advantages of country weeks or seashore air whenever possible.

Finally, the great problem of the management of tuberculosis in childhood is to prevent its spread. It is very easy to see what should be done, but very difficult to carry it out. In the first place, all children in families in which there is open tuberculosis should be removed and sent to the country or seashore. The schools should be inspected at least once in six months and those affected with tuberculosis sent to sanatoria. Fresh air schools should be established for the pretuberculous and proper provision should be made to provide them with extra food. Children suffering from latent tuberculosis and surgical tuberculosis should be sent to sanatoria separate from those for open tuberculosis. When they cannot be sent away they should go to day camps established for the purpose. Those suffering from early open tuberculosis should be treated in camps or sanatoria. The advanced cases should be treated by themselves in special hospitals. It is very evident, however, that this course cannot be followed at present because of the expense, which is prohibitive. In any case, the matter is too large a one for private charity and must be taken up by the municipalities and States. While these plans cannot be carried out as they should be, there is, however, no reason why everything that can be done should not be done.

#### PRECAUTIONS TO BE TAKEN IN COMING SOUTH.

By W. F. ROBINSON, M. D.,  
Palm Beach, Fla.

As an introduction to this article the writer may state that he has been engaged in the practice of medicine for eight years in hot climates, and that the statements made in this article are the result of his experience during this time.

It is often very amusing to one accustomed to the Southern country to hear the various opinions held among the laity in the North as to the advisability of coming South from the standpoint of health. If a person from the North comes to Florida and contracts an attack of diarrhoea he is apt to hurry home as fast as the train can carry him and warn all his friends not to go to that terribly unhealthy country, as they will be certain to get sick if they do go. Another tourist will contract a

severe cold and hurry home with the same story. A third will have a severe attack of indigestion, and he will be inclined to blame the country and think it a poor place to go to.

These cases occur constantly, and are very easy of explanation. First, the journey, like all journeys, is apt to be tiresome. The travelers perhaps lose their rest and are forced to go without sufficient food. As a result they arrive in a strange climate tired and worn out and with the system in the most favorable condition to contract disease of any kind. In addition to this, they often start right out and do extremely foolish things, either through ignorance or carelessness. Then they wonder why it is that they get sick in a climate that they have been told is so very healthy.

Let us see now if there is not some way to avoid illness under these circumstances and what had better be done.

First, in view of the inevitable fatigues of travel, people should be very cautious when arriving at their journey's end, especially if they arrive just before or at dark. In hot climates there is apt to be quite a little fall in temperature about this time. A person who has traveled through the heat and dust of a tropical day is naturally tired, hot, and probably perspiring; he is dressed perhaps in the heavy clothing which he put on when he started his journey in the cold North. The sudden coolness of the late afternoon seems very refreshing, but before he realizes he has become unduly chilled, and the next day he may be attacked with a severe cold, if he is fortunate enough to escape pneumonia or pleurisy.

The writer sees these diseases constantly, but has yet to meet the first case that was not contracted on the train or immediately on arriving. Every traveler should be provided with a good warm wrap and should be careful to wrap himself up well in it if he arrives in the cool of the evening.

If the traveler is delicate or perhaps convalescent from acute disease, it is an excellent plan to go to bed on arriving, and if hot and perspiring, an alcohol bath and a stimulant would not be amiss. On waking the next morning, if not fully rested and refreshed, it might be just as well to stay in bed during the morning or even the whole day.

In this connection the case of a strong, healthy man may be mentioned who came to Palm Beach last winter. The weather was cold when he left the North and he got a chill on the train. He was half sick when he arrived, but refused to rest or take any care of himself. Instead, he insisted upon going out on the beach, where a strong and cool sea breeze was blowing, and he lay down on the sand to rest himself and enjoy it. As a result of this indiscretion he was obliged to go to bed with a severe attack of pneumonia, from which he very nearly died. If this man had taken the simple precautions which I have mentioned he would in all probability have escaped the attack, or at least would have had it in very much milder form. Cases of this kind could be multiplied by the writer if there was any object in so doing.

*Diet.*—Another important matter in this connection is diet. Just as a change of air is trying at first to the throat and lungs, so a change of diet and wa-

ter is a strain upon the digestive function. In the first class hotels of the South the food is just about the same as in the North, so that there is nothing special to be said in this regard. There are two articles of diet, however, that deserve special mention, namely, fish and fruit. Both these articles are especially fine in the South, and it is just for this reason that it is necessary to utter a note of warning.

One can go out to the plantations which cluster around all the resorts and see growing oranges, tangerines, kumquats, guavas, grapefruit, pineapples, and many other tropical fruits. To a person who has never seen this before it is a beautiful and wonderful sight, and the first impulse is to buy a lot of the luscious fruit and have it sent to their rooms. Once there they are almost certain to indulge too freely and bring on an attack of acute indigestion. When a doctor is consulted they are much surprised to learn that the fruit is the cause of the trouble. It should be said in explanation that fruit is an excellent thing to eat and very healthy. If travelers would begin eating fruit in moderation until the system becomes accustomed to the new diet, they would receive benefit instead of harm. It is the sudden and excessive indulgence that causes the mischief.

As with fruit, so it is with fish. The fish of Florida is justly celebrated, and lovers of this kind of food often come South prepared for a great treat. There are many kinds of fish caught in Southern waters, and one or another of them are generally served at every meal, so that the fish lover may eat his favorite dish three times a day. If he does, the same result that happened in the case of the fruit is almost certain to occur, and for precisely the same reason. After one lesson of this kind the sufferer learns by experience and may eat fish in moderation all the rest of his stay in the South.

*Clothing.*—Just a few words of caution as to the matter of clothes. People coming South in winter naturally have on their heavy clothing, and when they arrive at their destination they find them very oppressive and are anxious to get rid of them as soon as possible. This is perfectly right, but it is very important that the change to lighter clothing be made in a proper way, otherwise harm may result. A peculiarity of hot climates is that it is often hot and close in the early morning, and then later a breeze will spring up and it will be quite a little cooler. Suppose a newcomer gets up in the morning and puts on fairly heavy clothes. He goes out in the sunshine and finds it very hot and uncomfortable, so that he is glad to come back and exchange his heavy clothing for much lighter fabrics. He finds these very much more comfortable and starts out again, but this time he finds it quite a little cooler, with a brisk breeze blowing, and before he knows it he feels chilly and has taken cold. In view of these facts the writer formulated a rule in the early days of his practice in hot climates which he has never ceased to preach to the newcomers whom he meets professionally or otherwise. The rule is this: Never change the clothes you have on for lighter ones during the day. Look out of your window in the morning on rising, and if the day is warm and sunny do not fear to put on the thinnest things you have in your trunk and go out. If you find them too thin as the day goes on, then is the time to change to your

rush of blood into the ocular vessels, exercising a deleterious influence upon the inflammatory process.

The most important drug in the treatment of inflammatory conditions of the iris is atropine, which should be used energetically and continued until its physiological effect upon the pupil is manifest. A complete dilatation of the pupil as well as a complete immobilization of the ciliary muscles is desirable. The drug should be employed in order to keep the pupil well dilated until all the inflammatory symptoms have subsided. Atropine is best employed in a one per cent. solution and is instilled as often as occasion requires. In the beginning of the disease one drop should be instilled every hour until complete dilatation has been obtained; after that one drop three times daily in the affected eye should be used to maintain the mydriatic effect. Poisonous effects in adults need not be feared; in children, however, symptoms of atropine poison may easily manifest themselves, so that sometimes the drug has to be withdrawn and substituted by some other mydriatic.

R Duhoisine sulphate, .....gr.  $\frac{1}{4}$ ;  
Distilled water, ..... $\text{℥i}$ .

M. Sig.: One drop in the affected eye three times daily.

R Scopolamine hydrobromide, .....gr.  $\frac{1}{4}$ ;  
Distilled water, ..... $\text{℥i}$ .

M. Sig.: One drop in the affected eye three times daily.

Rarely is it necessary to discard with the more powerful mydriatics on account of poisonous symptoms and substitute the less effective drug homatropine until the symptoms of poison have disappeared. The homatropine must be instilled every hour and in a 4 per cent. solution.

R Homatropine hydrochloride, .....gr. x;  
Distilled water, ..... $\text{℥ss}$ .

M. Sig.: One drop every hour in the affected eye.

During the course of treatment one should carefully watch the tension of the eye so as to be on the guard against a possible development of secondary glaucoma. A temporary rise in the intraocular pressure does not mean necessarily a glaucomatous condition. This may be observed during the course of the disease, at certain times lasting several hours. A good evacuation of the bowels and absolute rest will soon reestablish a normal relation. It is best, however, to stop the atropine for twenty-four hours. Should the tension not be reduced to its normal condition, eserine may be employed:

R Eserine sulphate, .....gr.  $\frac{1}{2}$ ;  
Distilled water, ..... $\text{℥i}$ .

M. Sig.: One drop instilled in the affected eye every hour.

One drop of this mixture instilled every hour will soon reduce the high tension. It is not very often necessary to have recourse to this measure. Still more rare is the necessity to employ surgical means in the endeavor to bring down the tension of the eye. The value of atropine in iritis exists in the fact that it dilates the pupil and thus guards against the development of posterior synechiae; it contracts the iris and thus reduces the congestion, and, paralyzing the ciliary muscles, it puts the iris in a condition of absolute rest, very essential in the treatment of all inflammatory conditions. Atropine occasionally fails to dilate the pupil; it is well then to combine it with

the other powerful mydriatics, especially scopolamine, when its action is enhanced. Not infrequently it happens that all the mydriatics combined fail to produce the desired effect upon the pupil until some constitutional remedies have been administered for their general effect.

The pain in iritis requires special attention. When the pain is not very severe and is caused by the congestive condition of the iris the instillation of atropine will bring relief. In some cases the pain is more marked and atropine does not bring the desired relief; hot compresses applied to the eyeball will be found of great value. The best and most convenient way is the hot, moist compress. The compress must be changed as soon as the water evaporates. In Germany hot camomile is commonly employed. Poultices of any kind are not necessary, and they are more difficult to prepare than the ordinary hot, moist compress. During the acute stage of the disease this compress should be steadily used. If the pain is not relieved by this method, then it is best to resort to bleeding. In hospitals blood may be withdrawn by means of the artificial leech (*Heurte-loup's*); in private practice this instrument is not practical, and it is best to employ the living leech. One or two leeches applied to the temporal region will in the majority of cases relieve the pain. If necessary they may be repeated. No bad effects result from their use, while the pain is always lessened, and in the majority of cases the pain is completely relieved. In some cases, however—and especially is this the case in rheumatic iritis—the pain in the eyeball and the orbital region radiating to the head becomes intolerable, and all agents previously mentioned fail to give relief; the patient is very restless, he cannot sleep, and is in misery indeed. Under such circumstances it is best to employ an anodyne and hypnotic. Morphine is the best agent. It is best to use it hypodermatically. It may also be incorporated with the other medicaments for the constitutional condition. In rheumatic iritis the morphine may be combined with the silicates:

R Sodii salicylatis, ..... $\text{℥ss}$ ;  
Morphine sulphatis, ..... $\text{℥iii}$ ;  
Potassii iodidi, ..... $\text{℥ss}$ ;  
Syr. sarsaparillæ comp., ..... $\text{℥i}$ .

M. Sig.: Teaspoonful every four hours.

Whenever morphine is employed to relieve the pain it is well to administer an aperient so as to keep the bowels in good shape. As soon as the pain subsides the morphine should be stopped, and it should not be given unless the indication for its use is manifest.

Adrenalin is a useless agent and may be harmful in some cases.

Darier employs a combination of dionin (ethyl morphine hydrochloride), cocaine, and atropine locally.

R Ethyl morphine hydrochloride, .....gr. ii;  
Cocaine, .....gr. ss;  
Atropine, .....gr. ss;  
Water, ..... $\text{℥i}$ .

M. Sig.: One drop in the affected eye six to eight times daily.

This is a very useful combination.

Dionin does not, however, relieve the pain, but is a useful agent in promoting the absorption of the

inflammatory product. In some cases it also enhances the action of atropine, and thus it becomes a valuable synergetic in our armamentarium in the treatment of this disease.

Hypopion complicating iritis does rarely require special treatment. Rest, hot compresses, diionin locally, and a cathartic will usually cause the exudate to be absorbed. In rare cases surgical interference (paracentesis) may be necessary.

*Posterior synechia.* As a result of the inflammatory exudation very often the iris becomes adherent to the anterior portion of the lens, either in part, or, as it rarely happens, in total. This, of course, requires our utmost attention. The ideal treatment is prevention. Should, however, after all the vigilance of the physician, adhesions develop they must have special care. A few small adhesions do no or very little harm, and they are, perhaps, better let alone. An effort may be made to break the adhesions by means of a strong mydriatic. Occasionally it is well to contract the pupil first with eserine, then followed by a counteraction with a strong solution of atropine. If no success follows this process it is best to discontinue the drugs. It must be remembered that the prolonged administration of atropine may give rise to a secondary glaucoma. Large posterior synechia, and especially the annular synechia, are dangerous to the eyes, not because they are responsible for the recurrences, but because they eventually destroy the usefulness of the eye by causing a secondary glaucoma. It is advisable to do an iridectomy, although even the surgical procedure is not always crowned with good result.

When we consider the fact that iritis is only a local condition when it is of traumatic origin, that in the vast majority of cases the causal element is to be found in some constitutional diathesis, we can then well appreciate the necessity of constitutional treatment. The local treatment is of great service in giving complete rest to the inflamed organ, reducing the congestion as far as possible, but it is the constitutional treatment that aims at the removal of the causal factor. In fact, the efficacy of the drug used for its local effect is made more potent by the administration of internal medication that produces a constitutional effect. A study of the constitutional disorder is therefore essential in the scientific application of therapeutic measures. In other words, the ophthalmologist must be a general practitioner as well, for the local inflammatory process will not yield to any local application unless a powerful impression has been made upon the constitution. Occasionally we find that the iris will not yield to the mydriatic influence of atropine, or even to a combination of the most powerful dilators, until we resort to general internal treatment we have been able to produce a constitutional effect upon the inflamed organ—in other words, the potency of the local application has been enhanced by the physiological effect produced with the constitutional remedies. The medical treatment of iritis is both local and general.

By far the most important constitutional remedies in this class are those to combat syphilitic diathesis. All ophthalmologists agree with Taylor that at least 40 cases out of 100 are caused by syphilis.

It occurs mostly in the secondary stage, and has a great tendency to recur. Syphilitic iritis usually runs a milder course, the pain being less acute. Mercury is, of course, the remedy *par excellence*. It is best administered in the form of an ointment. One drachm of the unguentum hydrargirum should be rubbed into the skin twice daily, choosing different parts of the body at each application. Should symptoms of mercurialism manifest itself the quantity of the drug should be reduced, while the intervals between the application should be made longer. During the application of mercury an alkaline mouth wash should be prescribed and the effect of the drug should be carefully watched. Occasionally it is necessary to entirely withdraw the mercury on account of poisonous symptoms. The inunction is very easily employed. The hypodermatic method, the only virtue of which is that it enables us to know the exact quantity of the drug absorbed, can only be applied by the physician, is painful, and patients are not willing to submit to it readily. When the inflammatory symptoms are declining, potassium iodide is of great value in promoting the absorption of the inflammatory product. Small doses of mercury should be given even after the eye shows no more signs of inflammation. It is the only safeguard against a recurrence, which is so frequent in syphilitic cases, and which I believe is often caused by an altogether too early withdrawal of the constitutional medication. When on account of gastrointestinal disturbances the syphilitic treatment has to be withdrawn for a short time the syrup of hydriodic acid will be found of great value. The next in frequency, as far as existing causes are concerned, is rheumatism. Whatever may be understood—at the present state of our meagre knowledge of this disease—by this term, so much is beyond any doubt, that it is a constitutional disease which very often gives rise to inflammatory conditions of the iris.

The iritis being a local manifestation of the constitutional disturbance, it runs a severe course, and is accompanied by intense pain. Here the salicylates are of great value. They are best given in powders. In the beginning of the disease and during the height of the disease it is best to administer large doses, while small doses are advisable in the declining stage of the inflammatory process. During the acme of the disease one drachm should be administered daily in ten grain doses. At bedtime it is well to give twenty grains, especially when the pain is marked. When the patient, on account of severe pain, cannot sleep, we may combine with the salicylates morphine. Very often by making a powerful impression upon the constitution we find that the salicylates not only help to relieve the pain, but help through general effect to dilate the pupil, which atropine alone could not do.

If the salicylates are insufficiently potent should be combined with the salicylates and should be given in five grain doses four times daily. When larger doses are prescribed it is well to guard the action of the heart.

Eliminative waters are useful in the treatment of iritis. The iron preparations are very often useful. In all syphilitic and rheumatic patients iron is of great value.

dispensable drug. This was best demonstrated in a case under my care, in which I could not affect a dilatation of the pupil by all the powerful mydriatics known until I administered Blaud's pill. In scrofulous cases the hypophosphates seem to have a favorable influence. Good results have also been obtained by the use of oil of gaultheria in gonorrhoeal rheumatism. In malaria quinine is, of course, indicated. Fresh air, good food, and judicious medication are essential in building up the patient's constitution so as to combat with the aid of local therapeutics the inflammatory process of the iris.

To prevent recurrences it is best to continue treatment after the inflammatory symptoms subside for a short time. This is very important, for recurring iritis always reduces the visual acuity, and in a considerable number of cases as a result of the sequelae the eye becomes a useless organ.

97 SPRUCE STREET.

### SOME UNUSUAL EFFECTS OF GONOCOCCUS INFECTIONS.\*

BY WILLIAM FRANCIS CAMPBELL, M. D.,  
Brooklyn, N. Y.

It was once thought that certain infectious diseases which manifested in a certain locality were purely local diseases. Now we know that pneumonia is no more a local disease of the lung than typhoid fever is of Peyer's patches. From more recent indications it becomes evident that gonorrhoea will have to take its stand as a general disease along with the others. It is true that in 80 per cent. of the cases gonorrhoea is localized, but with a margin of 20 per cent. for untoward effects, it is evident that affections of such a nature may manifest themselves in numerous ways.

A review of the literature on gonorrhoea shows that there is not a single organ in the body which at one time or another may not be the victim of such an infection. Should we add to this the indirect effects of gonococcaemia, the disease under consideration takes on a most serious aspect. It is because of its very commonness that it is dangerous. Beginning with the meninges of the brain and ending with a felon, the gonococcus has manifested an ability that other germs would find difficult to emulate.

Ever since it was demonstrated by Neisser, in 1879, the gonococcus has repeatedly been shown to be an inhabitant of places both remote and foreign from the common site of infection. Thus we read with peculiar interest the case reported by C. A. Powers where a diffuse and severe inflammation of the entire upper extremity of one side was found to be due to a mixed infection with gonococci and staphylococci. A little later this author was able to isolate the gonococcus from the neck, chest, and parotid gland of the same patient. No less interesting is the case of gonorrhoeal pleuritis, reported by Mazza in 1894. Here, too, gonococci were found.

We have become so used to hearing the expression "gonorrhoeal rheumatism," that from a surgical

standpoint it has ceased to be the subject of absorbing interest it was some time ago. One peculiar effect, however, that may be connected with this outcome of gonorrhoea, is the interesting fact developed a few years ago by R. Kienbock. According to this investigator a protracted gonorrhoeal arthritis, especially of the wrist, is productive of a high grade of rarification of the bones attacked. We can easily imagine what this means to the bone.

Although not coming directly under the theme of this paper still because of the bearing it may have, a few figures in connection with gonorrhoeal arthritis may be cited. From 100 cases collected at random the gonococcus pure was found in 4 per cent., mixed in 13 per cent., and in 83 per cent. no organisms were found at all, the diagnosis being made from the history, objective and subjective symptoms, etc. In twenty-four cases mentioning the time of occurrence of the joint affection, fourteen followed the first attack, six the second, and of the four remaining cases, one occurred after the third, and three after subsequent attacks. In twenty-one of these twenty-four cases the disease ran a chronic course.

In connection with the subject of arthritis the case reported by Baer is worthy of attraction. His patient, the subject of acute gonorrhoea, had injured his wrist, but there was no open wound. After a short time the wrist swelled and became purulent. Gonococci were demonstrated in the pus.

Of further interest may be the statement of some authors that they obtained no toxine from the contents of joints the subjects of gonorrhoeal inflammation. However, once the gonococcus has invaded the blood, there is no knowing where it will strike, and the surgeon might just as well be ready for an abscess of the liver with this germ as the causative factor, as he is for pyosalpinx or suppurative prostatitis.

An effect not very common, but by no means rare in gonorrhoea and where the blood plays the leading rôle, is "gonorrhoeal pyæmia." While this turn of the disease is probably as old as the disease itself, the first case reported is that by Roswell Park, who, at a meeting of the Genitourinary Surgeons held in Washington in 1888, spoke of a case under his care where pyæmia followed acute gonorrhoea. When two weeks after the infection the discharge ceased, it was followed shortly by swollen knees, sepsis, a typhoidal condition, and death. At the autopsy pus was found in the sternoclavicular articulation in which also there was erosion of bone. Other joints also contained pus. The mesenteric gland and the spleen were enlarged. Dr. Park was not certain whether this was the patient's first attack of gonorrhoea, and he was not acquainted with the condition of the urethra before the attack.

Other cases have been reported since then, interesting among which is that of Silverstrim in whose patient the attack among other things caused great enlargement of the liver and icterus; and of T. J. Strong's patient in whom a metastatic focus formed and presented a large abscess in the neck.

Strange as it may seem cases of gonorrhoeal peritonitis have also been reported occurring in the male. Thomas reported two such, but very recently.

\*Read before the New York Medical Club, November, 1907.

A distressing surgical complication in which the gonococcus plays an important part is that of gonorrhoeal proctitis. According to König the affection is most frequent in the female sex, the ratio between the sexes being 1 to 8. He states that the gonococci are seldom demonstrable in the excreta and that the process may extend into the flexure, or by causing pararectal abscess lead to fistula. He mentions a case where perforation occurred into the vagina.

Though we are ready to be amazed at his report, Meyer brings it down to the commonplace when he declares that in his case of a felon from which the gonococcus was obtained in pure culture, contact infection was the responsible factor. This patient was a woman, twenty-three years of age, affected with gonorrhoeal vaginitis and multiple arthritis. A short time previous to admission she had injured the radial side of the index finger of the right hand by means of a small iron instrument. Three days after this accident a blister about the size of a quarter developed at the point of injury which contained thick, yellowish pus, and its base presented a ragged appearance. The skin defect took three and one half weeks to heal. The tendons and joints in the immediate neighborhood were not affected.

Less fortunate than this patient was the one reported by Jacobi and Goldman, who, following an injury of the tendons of the wrist and while the subject of gonorrhoeal infection, became afflicted with tendovaginitis, which left a kylosed joint.

The ability of the gonococcus to localize itself at a point where we would least suspect it, is further illustrated by the case of M. A. Gershel, who reports positive findings in a subcutaneous abscess in a child two years of age. The child was taken down with typhoid fever, and two days after admission to the hospital gave symptoms of gonorrhoea the origin of which could not be determined. The abscess occurred a week after admission and presented at the left of the anus. Three days later a similar abscess presented at the right side. Other cases with gonorrhoeal abscess of the skin and subcutaneous tissues have also been reported.

CASE.—On January 2, 1907, a male, eighteen years old, was thrown from a wagon and sustained a compound Pott's fracture. He was treated with all aseptic precautions, drained, and the limb immobilized in splint. Four days later pus appeared in the wound and continued to spread up the leg as far as the thigh, requiring extensive incisions about the leg and thigh to secure adequate drainage. Without any reference to the gonococcus, but desiring to find the germ cause of the extensive suppuration, a culture was made from the wound discharge a month after admission, and the gonococcus found. It was then discovered that the patient was suffering from gonorrhoea, a fact which had not been obtained on his admission to the hospital. He stated that he had acquired the infection three days after being exposed, about six weeks previous to his admission to the hospital. After four months the patient was discharged from the hospital cured with regard to the fracture, but still having slight urethral discharge. In this case infection by direct contact was impossible while the patient was at the hospital, and the cause of the suppuration can only be accounted for in two ways, (a) either the gonococcus circulating in his blood found a point of low resistance and there set up an focus, or (b) at the time of the accident the patient may have become inoculated from the germ in question present on his clothing. Personally I am inclined to believe the first of these suppositions to be the correct one.

## CARCINOMATOUS DEGENERATION OF BREAST CYSTS.

BY JOHN SPEESE, M. D.,  
Philadelphia,

Assistant Instructor in Surgery, University of Pennsylvania.  
Surgeon to the Dispensary of the Children's Hospital.  
From the Laboratory of Surgical Pathology, University of Pennsylvania.

The subject of precancerous conditions in the female breast is one which is ever of importance to the surgeon. The recognition of these conditions along with improvement in diagnosis and the education of the laity toward the appreciation of their significance, has led to our present success in operative measures. While the percentage of cures is increasing, we can hope for further advance only by careful observation and prompt surgical intervention in all cases which have any tendency toward malignancy. It is well known that the disease commonly termed chronic cystic mastitis, because of the marked tendency toward epithelial hyperplasia, frequently undergoes carcinomatous degeneration.

In a recent paper<sup>1</sup> I called attention to the fact that this degeneration occurs in a fairly large percentage of cases, 12 to 16, and since that series was collected I have had the opportunity of seeing three additional instances of malignancy secondary to chronic cystic mastitis. We find carcinoma likewise developing secondarily in other benign diseases, Greenough and Simmons<sup>2</sup> asserting from their studies that 15 per cent. of papillary cystadenomata undergo cancerous change. Cases have been carefully studied in which a malignant process apparently originated in the lining of cysts, a part of the series of changes observed in abnormal involution. References to such a transformation in the case of simple retention cysts are, however, meagre. Because of this danger and the necessity for its observance the writer is led to regard the condition as precancerous and, therefore, one demanding consideration.

The case which forms the basis of this paper occurred in the service of Dr. Edward Martin, to whom I am indebted for permission to report it. The history of the case is as follows:

The patient, aged sixty-seven, the mother of five children, gave an absolutely negative history in regard to mammary trouble. Nine months before her admission to the hospital she received a blow over the left breast, the force being of moderate severity. A short time after this, she noticed in the outer side of the breast a small nodule which was tender on pressure. The growth of the tumor was very slow at first, but during the two months before her admission it had quite perceptibly increased in volume. Accompanying this change the skin became purple in color, and there was constant, although not severe pain. On examination, a mass the size of an orange was detected in the lower and outer quadrant of the breast. Over its surface numerous large veins were seen, and fluctuation was elicited in the tumor which was freely movable on the underlying structures. There was no retraction of the nipple, the skin was slightly adherent to the growth, and a few axillary nodes were found enlarged and indurated.

While the cystic character of the tumor was appreciated, the possibility of malignancy due to the patient's age, the adherence of the skin, and the enlargement of the axillary lymph nodes demanded a radical operation. Accordingly the entire breast, including the cyst, was removed, and the

and has remained well for the sixteen months since the time of operation.

On opening the cyst, which was situated directly beneath the skin to which it was adherent, a thin, black fluid was evacuated. In view of the history of trauma, the color of the fluid was believed to be due to degenerated blood. The wall of the cyst presented a peculiar reticulated appearance, not unlike that seen in the ventricles of the heart. The remainder of the breast was in no way different from that seen in the state of normal involution, a fact confirmed by the microscopical examination. The histological examination of the cyst wall showed an infiltration of cells, epithelial in character. Numerous sections failed to reveal the point from which this invasion began, due possibly to marked degeneration and atrophy of the lining membrane of the cyst. The carcinomatous areas consisted of closely compressed cells arranged in thin processes, not unlike a scirrhous cancer. The surrounding tissue was almost devoid of glandular elements and was typical of an involuting breast. The case represents then the rather uncommon malignant degeneration of the lining of a retention cyst of the breast. The thorough examination of the surrounding mammary tissue excluded the possibility of a carcinoma infiltrating the cyst wall from without.

A discussion of the varieties and mode of formation of breast cysts, is not the object of this paper. References are not common in the literature concerning the formation of a malignant growth in a preexisting cyst although it is well known that cyst formation often results in malignant tumors. At one time it was denied that a cancer could primarily arise from a cyst, but recent studies have shown the contrary to be true. The occurrence of malignancy in fibroepithelial formations has already been alluded to. Occasionally we find a cancerous invasion of the cyst wall from without, the process developing primarily in the breast. Such a case is reported by Sheild.<sup>3</sup> While the origin of the carcinoma in many cases is not clear, the retrogressive changes which the epithelium undergoes is largely the cause of the malignant degeneration. The columnar cells become compressed as the result of the pressure exerted by the contents of the cyst, and are transformed into cuboidal or flat cells, or may undergo atrophy. In addition, retrograde changes in the fibrous wall may be detected; these varying factors having a more or less important rôle in the malignant degeneration which may follow. The actual origin of the cancer is not so important when once the disease is well established, for a radical operation is immediately indicated.

The diagnosis according to Sheild depends upon the age of the patient, the majority being forty to fifty years of age. Rapid enlargement of the cyst, especially if followed by the involvement of the axillary lymph nodes, should be regarded as very significant of beginning carcinomatous degeneration. The cysts are large, as a rule, round or oval in shape, and the contents clear, amber colored, or discolored by blood. In the majority of cases the presence of blood in a cyst, without an intracystic papilloma to explain the hemorrhage can be regarded according to Bloodgood,<sup>4</sup> as diagnostic of malignancy. When cysts are opened at the time of operation the lining should be carefully examined for thickened or indurated areas, and papillary projections. The latter in particular are apt to be overlooked, and even when quite small may be the seat of an early but highly malignant process. A case illustrating this danger was recently observed. An apparently benign cyst was re-

moved, and only on a second and more careful examination was a suspicious papilloma discovered. This, on microscopical examination, proved to be a malignant papillary cystadenoma, a fact which altered the prognosis and treatment of the case to a considerable extent. Aspiration of cyst contents as a diagnostic aid is no longer regarded as a proper surgical procedure, for if not immediately followed by operation much harm may result.

The treatment of cancerous cysts differs in no way from that of any malignant tumor of the breast. While in many cases the degree of malignancy is low, we are not justified in temporizing, but should resort to the usual radical removal when on inspection of the cyst contents and its walls, malignancy is suspected.

328 SOUTH SIXTEENTH STREET.

#### NOTES ON DENGUE IN CUBA.

By A. H. ALLEN, M. D.,  
Lajas, Santa Clara, Cuba,

Assistant Surgeon, United States Navy.

(Published under the Imprimatur of the American Society of Tropical Medicine.)

The towns of Lajas and Santo Domingo are situated about forty miles from the sea coast in the interior of Santa Clara province. Mosquitoes are abundant during the entire year, the most frequent species being the stegomyia, culicidæ, and anopheles, in the order named.

In August of 1907 I observed some cases of dengue fever which are reported on account of their mild character and failure to assume an epidemic form. In all, there were eighteen admissions to the sick list in two companies of United States marines stationed in the two towns mentioned.

*Incubation.*—The incubation period in one patient was three days, in two patients four days, in the others unknown, but probably not over three or four days.

*Prodromes.*—There were no prodromal symptoms, the first sign of the disease being frontal headache and vertigo, which were pronounced. Pain in the eyeballs was a prominent symptom in every case. Only one patient had severe pain in the joints, although six complained of pain in the loins and back, and all complained of a very slight rachialgia. One patient had abdominal pain with vomiting and diarrhoea, which lasted for twelve hours. In all patients the digestive system showed only the ordinary signs of the febrile state. In no case was pain a prominent feature.

Defervescence started on the first or second day, without crises of any kind.

*Rashes.*—The rash appeared on the second or third day. The so called "primary" rash was present in five cases. The face was flushed and the mucous membranes of the nose and throat were somewhat congested. The conjunctiva was slightly reddened. This condition disappeared in from twelve to twenty-four hours, either before or during defervescence, and was succeeded by the typical rash. This eruption showed a preference for the dorsal surface of the forearms, internal surface of the thighs, and the back and chest. It was present

in all cases. Its character was discrete, roundish maroon, or reddish spots from one quarter to three quarter inches in diameter, slightly raised. On the forearms and thighs the spots rapidly coalesced; on the back and chest they remained comparatively discrete. In one case the rash on the arms and neck gave the appearance of a severe sunburn. Fading took place in from twelve to twenty-four hours in the majority of cases, although in one the rash persisted for seventy-two hours, and in three for forty-eight hours. A very slight furfuraceous desquamation succeeded its disappearance.

**Glands.**—In three cases the superficial cervical glands were enlarged. In fourteen cases the inguinal glands became swollen without pain, although the fact that most of these patients had a previous venereal history must be noted.

**Temperature and Pulse.**—The highest temperature was  $103^{\circ}$  F., which occurred on admission, the average being about  $102.2^{\circ}$  F. The pulse was uniformly low. With fever of  $103^{\circ}$  F. the pulse was 92; with temperatures of  $102^{\circ}$  F. in six cases the pulse varied from 80 to 100. The highest pulse rate was 102.

**Blood.**—No blood examination was possible, as there was no microscope available, and the United States Army Hospital at Cienfuegos, Cuba, was contending at the time with an outbreak of yellow fever.

There was no albuminuria or any tendency to hæmorrhage in any case.

**Transmission.**—The theory of Graham and Bancroft, who consider the mosquito the infective agent, seems to receive some corroboration in these cases. In previous reports the presence of one case of dengue is soon followed by an epidemic. In these cases the barracks were fumigated with sulphur dioxide to destroy all infected insects, and the use of the mosquito bar was rigidly enforced. The patients were immediately removed to a screened building and treated under mosquito nets. One case of a hospital apprentice, who nursed the cases and was attacked with a typical seizure of the disease three days later, was thought to be due to lack of care in the use of the bar, as another apprentice, doing the same work, yet protecting himself securely at night, was not attacked with the disease.

**Conclusion.**—In summing up, the most noticeable features of the cases were the uniformity of the rash, the very slight amount of pain associated with the disease, the comparatively low pulse, the mild character of all cases, and the possibility of the mosquito being the transmitting agency of dengue.

### Correspondence.

#### LETTER FROM TORONTO

*The New Year of the Toronto General Hospital.*

Toronto, February 16, 1915.

For over sixteen months the special committee of the board of governors of the Toronto General Hospital have had under consideration a proposition to the staff of that hospital. Their final report has been made, and it has been very definitely laid down, especially when attached to hospitals with the little influence under the rule of men who have

years zealously and faithfully performed their duties. Were it only the older men who had got it, one would not grumble that they had been laid upon the shelf as "consulting staff," an honor of very doubtful value; but when many young men, who had done their work well, regularly, and constantly, are interestedly sacrificed, their sole fault being that they were not wire pullers, and had not sought any influence on the board to back them up, the injustice is so rank that it is almost surprising that even some of the good and high class ethical men on the new staff did not refuse to continue when some of their late confrères got it so "good and plenty." Of course, hospital boards must cater to the protégés of munificent donors—*verb. sap.*

The three heads of the department of surgery are Dr. George A. Bingham, Dr. Alexander Primrose, and Dr. H. A. Bruce. Dr. Bingham has under him Dr. Charles Shuttleworth, Dr. Wallace Scott, and Dr. A. B. Wright. Dr. Primrose has Dr. F. N. G. Starr, Dr. Stanley Ryerson, and Dr. S. H. Westman; Dr. Bruce, Dr. W. J. O. Malloch, Dr. Warner Jones, Dr. John McCollum, and Dr. A. A. Beatty. Mr. I. H. Cameron, as professor of surgery in Toronto University, is chief of the surgery class, and attached to him is Dr. Clarence L. Starr. There are three services in medicine, with Dr. Alexander McPhedran, Dr. W. P. Caven, and Dr. Graham Chambers as heads. Assisting Dr. McPhedran are Dr. A. R. Gordon and Dr. William Goldie; Dr. Caven, Dr. John Fotheringham, Dr. W. B. Thistle, Dr. E. C. Burson, and Dr. Joseph S. Graham; Dr. Chambers, Dr. R. D. Rudolf, Dr. Goldwin Howland, and Dr. George W. Ross. In charge of the tuberculosis clinic under Dr. McPhedran's clinic is Dr. H. C. Parsons. In charge of the department for the treatment of functional neuroses, under Dr. Caven's service, is Dr. D. C. Meyers. Dr. J. F. W. Ross is chief of the gynecological department, and associated with him are Dr. F. W. Marlow, Dr. W. B. Hendry, Dr. A. C. Hendrick, Dr. Ida Lynd, and Dr. Helen McMurchy. The obstetrical service is in charge of Dr. Kennedy McIlwraith, with Dr. Frederick Fenton and Dr. J. A. Kinnear as assistants. In the eye department are Dr. R. A. Reeve, chief, and Dr. C. Trow, Dr. J. M. MacCallum, Dr. D. N. MacLennan, Dr. Colin Campbell, and Dr. W. H. Lowry. The ear, nose, and throat department is under the charge of Dr. George R. McDonagh, with Dr. D. J. G. Wishart, Dr. Geoffrey Boyd, Dr. Perry Goldsmith, Dr. C. M. Stewart, and Dr. Gilbert Royce. Dr. Samuel Johnston will be the chief anæsthetist and Dr. D. M. Anderson assistant. Dr. Charles R. Dickson will continue to look after the electrical department, with Dr. George Balmer as assistant. Dr. J. A. Temple and Dr. F. LeM. Grasett had the cinch on the board, as they were life members of the Burnside Lying-in Department, and so could not be ousted. There have been associated life members of the active staff without service. The committee recommended the following old and new members as honorary members as consulting staff, although some of them are not yet entitled to sit in the "deliberated zone." In medicine: Dr. John L. Davison, Dr. W. H. B. Aikins, Dr. T. F. McManus, Dr. A. J. Paton, and Dr. John Owen. In surgery: Dr. Luke Teskev, Dr. R. B. Nevitt, and Dr.

N. A. Powell; in obstetrics, Dr. Adam H. Wright; in the eye and ear department, Dr. G. Stirling Rye-son, and Dr. George H. Burnham. Whether this "sop" will be satisfactory in removing any cardiac ulcerations it is hard to say. Those, however, who were so relentlessly and ruthlessly pole-axed may lay this flattering unction to their wounded feelings, which in the process of time, especially the time, may heal them: The committee expressed its appreciation of the excellent character of the service rendered by the staff, past and present, and in addition its grateful acknowledgment of the self sacrificing efforts in the interests of the sick and of medical education on the part of members now retiring (retiring is good), several of whom have been connected with the hospital for long periods, and have requested to be relieved from further duty—(but not chloroformed). There is balm in Gilead.

### Therapeutical Notes.

**Cocaine in Ointments.**—There exists an impression that when cocaine is prescribed in an ointment the alkaloid and not the hydrochloride should be used, on account of the insolubility of the latter in oils and fats. The hydrochloride, however, is more suitable in the majority of cases, for, if the ointment is to be applied to the eye or to a mucous membrane, the moisture will dissolve the salt and cause much more rapid absorption than if the alkaloid were employed. If wool fat is used as a basis, the water contained therein will dissolve the salt better than the fat will the alkaloid, and absorption will be immediate. According to Cripps (*The Prescriber*, February, 1908), the pure alkaloid is liable to decomposition in presence of fats.

**To Abort Lobar Pneumonia.**—The question of the abortion of an apparent first stage of pneumonia is discussed in the *Journal of the American Medical Association* for February 15. Except in instances in which the sputum has been found to contain pneumococci, and, under measures instituted, the congested lung has cleared up in a day or two, we are not justified in asserting that an attack of pneumonia has been aborted. On the other hand, with assistance and without assistance, we all see instances of congestion of one lobe of a lung occur, stop, and become normal in two or three days. Unfortunately, at this period of an apparent pneumonia there may be no sputum, and if there is, it is not examined for pneumococci, and it may not have been a pneumonia at all, but certainly it was a congestion of one lobe of a lung. Consequently an attempt to abort an apparent first stage of pneumonia should be made. If the patient is strong, sturdy, and especially if he is plethoric, venesection will often give good results, and is positively indicated if there is marked dyspnea, if the heart is laboring, the head full, and the face congested, even if there is no actual cyanosis. Life has been saved by venesection done under such conditions. If the symptoms are not dire enough to demand venesection and for other reasons it is deemed inadvisable, which is generally the case, a full dose of an antipyretic drug, such as antipyrine, sufficient to cause profuse sweating, is good treat-

ment. The antipyrine may be given in fifteen grain doses combined with calomel, unless there is sufficient pain to require an immediate dose of morphine. If the pain is severe, morphine should not be delayed, but given, if necessary, hypodermatically, in a dose sufficient to stop the pain, either 1/8 or 1/6 of a grain. It is better to repeat the dose of morphine when needed rather than give as large a dose as 1/4 of a grain, which will, perhaps, produce more profound sleep than is desired. If morphine is given for the first acute pain, a saline purgative should be given on the following day.

**Treatment of Biliary Calculus.**—A pill of the following composition is said to be useful in the treatment of biliary calculus; the formula being credited by the *Journal de médecine* to Gilbert Davis:

R Phenolphthaleine, ..... gr. 1/4;  
Sodium oleate, ..... gr. i;  
Salicylic acid, ..... gr. iss;  
Menthol, ..... gr. i.

M. ft. pil. No. i.

Sig.: One pill two or three time a day.

**Thymol Camphor in Abscesses.**—The liquid produced by mixing thymol and camphor is recommended by Risacher (*Journal de médecine de Paris* and *The Prescriber*) for reducing fungosities of a tuberculous character. Injected into abscesses it has two special actions: (1) An immediate action, permitting the rapid evacuation of a fungous abscess, or at least it relieves its tension and avoids formation of a fistulous tract; (2) a mediate action, which it exercises upon the contents of the abscess at the end of a few days; aspiration, at this time, brings away a viscid, chocolate colored fluid, of distinct camphoraceous odor. The injection is not followed by a fistula; the tract closes up in a few days and leaves no induration. In the case of a tuberculous lymph gland, a few drops of the solution are to be injected into the interior. After two or three injections, the gland becomes soft and fluctuates, and can then be treated like the preceding. In this way it is possible to remove strumous glands without producing a cicatrix, which the patient so much dreads, and which may become affected with keloid. No unpleasant symptoms follow these injections, unless the liquid should be accidentally thrown into a vein. The proportions recommended are thymol 16, camphor, 30.

**To Promote Diuresis in Uræmia** the following pills may be given:

R Extract of pilocarpus, }  
Extract of squill, } ..... aa gr. i.

M. ft. pil. No. i.

Sig.: One pill every three hours.

R Pulverized squill, }  
Pulverized scammony, } ..... aa gr. i.  
Pulverized digitalis, }

M. ft. pil. No. i.

Sig.: One pill every three hours.

To overcome œdema of the limbs the following powder is recommended:

R Potassium sulphate, ..... 3iss;  
Potassium bitartrate, ..... 3iss;  
Potassium nitrate, ..... 3iss;  
Powdered digitalis, ..... gr. xv.

M. et divide in chart xx. One to three powders a day, as needed.

**Hæmaturia in Hæmophylics.**—The treatment of bleeding from the kidneys is considered in an article in the *Journal of the American Medical Association* for February 15. In hæmophilia various drugs may be tried. Suprarenal extract may do good, and thyroid extract has often been of advantage, although in other instances it tends to increase the hæmorrhage. The exact element in the blood that is wrong or the exact internal secretion that is at fault in hæmophilia has not been discovered and may not be constant, hence the varied results from the administration of the various organic extracts. Gelatin has been fed with advantage in such instances, and calcium chloride has often been of benefit. Calcium chloride may be given as follows:

R Calcium chloride, ..... 5ss;  
Syrup of calcium lactophosphate, ..... ʒiv.  
M. et sig.: A teaspoonful, with plenty of water, every three hours.

**To Increase the Flow of Milk.**—To increase the flow of milk when it is desired to defer weaning the infant or changing the nurse it is often recommended to the nurse to take malt beverages such as light beer or ale and to use additional salt in the food. Certain aromatic and carminative drugs are also reputed to be of service, cumin, anise and fennel seed being used. In the *Journal de médecine de Paris*, for January 25, 1908, it is noted that Professor Del Arca, of Buenos Aires, recommends an infusion of the root or a decoction of the seeds of what is evidently an Argentine plant, tasi, the botanical name of which is given as *morrenia brachystephana*.<sup>1</sup> The preparations are made according to the following formulas:

*Infusion of the root:*

R Tasi root, ..... 30 parts;  
Boiling water, ..... 200 parts.  
Make an infusion and strain. To be taken in doses of one tablespoonful during twenty-four hours.

*Decoction of the seeds:*

R Tasi seeds, ..... 40 parts;  
Water, ..... 200 parts.  
Make a decoction by boiling.  
To be given during the day in tablespoonful doses.

In France the following preparations of nettle and galega (goats' rue) are employed as galactagogues:

R Galega leaves, ..... 50 parts;  
Make an infusion with  
Water, ..... 1,000 parts;  
And add  
Syrup, ..... 100 parts.

The whole of this is to be given during the twenty-four hours.

An aqueous extract of galega finds favor, made as follows:

R Extract of galega, ..... ʒss;  
Simple syrup, ..... Oil.  
M. Sig.: Tablespoonful every three hours.

A tincture of galega, made from the extract, is also employed:

R Extract of galega, ..... ʒss;  
Diluted alcohol, ..... Oil.  
M. Sig.: Fifty to 100 drops three or four times a day.

Galega may also be prescribed in pill form as follows:

R Galega, ..... ʒss;  
M. Sig.: One pill three or four times a day.

R Extract of galega, ..... ʒss;  
Excipient, ..... q. s.  
M. ft. pil. No. 1.  
Sig.: One pill three or four times a day.

Monin recommends the following compound pill:

R Extract of galega, ..... ʒss;  
Extract of nettle, ..... ʒss;  
Extract of orange, ..... ʒss;  
Calcium hypophosphite, ..... ʒss;  
Essence of cumin, ..... q. s.  
M. ft. pil. No. 1.  
Sig.: One to two pills twice or thrice daily with meals.

A tincture and a syrup of nettle are used in the same dosage, though the nettle preparations are more concentrated:

R Extract of nettle, ..... ʒss;  
Diluted alcohol, ..... Oil.  
M. Sig.: One to two teaspoonfuls every three hours.

*Syrup of nettle:*

R Extract of nettle, ..... ʒss;  
Simple syrup, ..... Oil.  
M. Sig.: Tablespoonful every three hours.

Potassium chlorate in doses of fifteen grains three times a day has been recommended by Harkin, of Belfast, but this drug must be used with caution.

**The Treatment of Chilblains** is thoroughly discussed by F. Gardier in *The Practitioner*, for February, 1908. He names ichthyl and formaldehyde as two drugs of preeminent value in the early stages. Ichthyl reduces congestion. While he has used it in full strength painted on, an ointment of wool fat containing ten to twenty per cent. of ichthyl serves most purposes. Spread thickly on linen, and worn at nights on the affected parts, ichthyl ointment often dispels a commencing attack after a few applications. If the odorous character of ichthyl is objected to, thigenol may be used in its stead. Formaldehyde requires more care in its application in consequence of its pungent odor and smarting effects on abraded surfaces. In ointment form it may be used in ten to fifty per cent. strength. Formaldehyde may be also applied pure. It is said to be more effective and lasting in its results, but much harsher in its action, therefore ichthyl is better suited for delicate skins. Exposure of the surface to x rays and high frequency currents have been used successfully in severely recurring cases. X rays are said to have an atrophic effect, this being more pronounced on unhealthy tissue, hence they reduce inflammation and remove pain. High frequency currents can be applied by the effleuve, or by the vacuum electrode. In the ulcerating stage the following paste forms a convenient application:

R Ammoniated mercury, ..... ʒss;  
Ichthyl, ..... ʒss;  
Starch, ..... ʒss;  
Zinc oxide, ..... ʒss;  
Petrolatum, ..... ʒss.

M. Sig.: Apply unsparingly on linen and change frequently.

**Inhalation for Whooping Cough.**—Edson (Practitioner) uses the following:

R Camphor, ..... ʒss;  
Essential oil of eucalyptus, ..... ʒss;  
Spt. chloroform, ..... ʒss;  
M. Sig.: Use inhalation fifteen to twenty times a day.

M. Sig.: Use inhalation fifteen to twenty times a day.

NEW YORK, SATURDAY, FEBRUARY 22, 1908.

SUPRARENAL PREPARATIONS IN  
DERMATOLOGICAL DIAGNOSIS.

Dr. Winkler, of Germany, has made interesting researches and experiments regarding the influence of adrenalin, hydrochloride of suprarenine, and synthetic suprarenine upon the skin, in which he gained the impression that the synthetic preparation did not act so well as the two natural ones.

He reports his results in the *Monatshefte für praktische Dermatologie* for February 1st, and refers to Alois Velich, who described his experiments in the *Wiener medizinische Blätter*, 1897, p. 735, and to Julius Baum, who wrote about the same subject in the *Archiv für Dermatologie und Syphilis*, 1905, p. 59.

Painting of uninjured skin with suprarenal preparations is not followed by any effect. But Winkler's method produces results; that is, if a thin layer of cotton wool impregnated with a suprarenal preparation is placed upon the uninjured skin and kept there under light pressure for about ten minutes, the area thus treated will remain white for about thirty minutes to four hours, according to the vaso-motor excitability of the skin, when it gradually resumes its normal color. Painting with the preparation makes only injured skin anæmic, such a lesion being produced by lightly rubbing with fine emery paper or ether. Furthermore, if a line is marked with a blunt glass rod upon a skin of ready vaso-motor excitability, this line will immediately become elevated and red, marked on both sides with a white

line; this red elevation, when covered with suprarenal wadding, will disappear and form with the white lines a broad white band. If the glass rod is applied to an area whitened by a suprarenal preparation in such a manner that uninfluenced skin is also touched on both sides, then the area will be surrounded by red and white lines, while the area itself becomes only slightly elevated.

These experiments have been used for diagnoses in dermatology. Thus, when an area of lupus vulgaris has been treated in the manner described, the red nodules will stand out prominently from the anæmic skin, while the brown red syphilides turn gray yellow, and in sclerosis a yellow coloring appears. Lupus erythematosus is not affected, while lupus tumidus shows a result. Erythema multiforme and erythema nodosum are strongly influenced, the bluish color disappearing. In a skin upon which suprarenal wadding has been placed and which is then treated with radium, the radium erythema does not appear, while, when it is present, the skin not having been treated with the suprarenal preparation, it will disappear on the application. Urticaria blotches pale and the itching stops. The redness of acute articular rheumatism disappears entirely, but that of syphilitic origin turns gray. In psoriasis the red scales turn white, and if there is desquamation, can easily be picked off.

Of interest is also the influence of suprarenal preparations upon eczema, where the rose red nodules in seborrhœic eczema turn yellow, thus distinguishing eczema from lichen urticatus, where the entire area is paled. In herpes zoster the vesicles do not change color, while the surrounding area pales slightly. Evidently the suprarenal preparations may find a place in dermatological diagnosis.

## A MUSEUM OF SAFETY DEVICES.

The establishment of the American Museum of Safety Devices and Industrial Hygiene seems to promise the adoption of many efficient means of preventing fatal and crippling accidents and the occurrence of disease due to causes now incident to certain occupations. It appears to us more likely than the enactment of an employers' liability law to promote the saving of life and health; at all events it may powerfully supplement such a law and restrict the necessity of resorting to its provisions.

At present the museum occupies the fifth floor of a large building at No. 231 West Thirty-ninth Street, near Broadway. There is no charge for admission to the display, which is open to the public daily from 10 a. m. to 6 p. m., except that on Saturdays it closes at 1 p. m. It is announced that special

arrangements can always be made for visitors on holidays and during conventions and "other events," also that competent persons will be in attendance to explain the devices and processes exhibited. An "industrial chamber of horrors" is to be made a feature of the museum, showing the unsuspected perils to which we are almost all frequently exposed, such as defective pieces of mechanism in passenger elevators, for example.

Certain prizes are announced. The *Scientific American* offers annually a gold medal for the best device for the protection of life and limb, limited for this year to devices pertaining to transportation. Dr. L. L. Seaman offers a prize of \$100 for the best essay on the economic waste due to occupational diseases, and a person whose name is not given offers a prize of the same amount for the best essay on the economic waste due to accidents. It is reasonable to suppose that other prizes will be open to general competition, and we may well hope that beneficent results will follow.

The museum is under the patronage of men whose names are a guarantee that its operation will be free from objectionable features. Bishop Potter presided at a meeting held in the Cooper Union on February 11th, in furtherance of the work of the museum. At that meeting addresses were made by the Hon. Carroll D. Wright, Rabbi Stephen S. Wise, Mr. Alfred J. Boulton, the Rev. Percy S. Grant, Dr. Josiah Strong, and Dr. William H. Tolman (the director of the museum). We understand that this undertaking is dependent for its financial support solely on the fees received from exhibitors and on contributions, and we hope that the latter will prove numerous and substantial. The treasurer is Mr. William B. Howland. A contribution to the funds of the museum would seem to be a direct benefaction to the people; not the people of New York alone, but also of the whole country.

#### ANATOMY AND PHYSIOLOGY AMONG THE CHINESE.

As we hear only severe criticism of the knowledge of medicine among the Chinese, we wonder how it is possible that a nation which is so highly cultivated and possesses such an old civilization could have been satisfied for many centuries with ignorant physicians. Dr. Grünhagen, of Schwerin, Germany, is therefore to be congratulated on having published in *Janus* for January a very interesting and instructive article dealing with this subject.

We hear from our learned author that since the seventeenth century the Chinese physicians have not been permitted to perform autopsies, partly from

religious respect for the dead, partly from the belief that every man should enter the other world with an uninjured, whole body, that he may lead a peaceful life in the hereafter and may not disturb his descendants. The anatomical knowledge of the Chinese dates, therefore, back to the time before this period, when post mortem examinations were still performed, and this knowledge has come to the Chinese of the present day as a tradition preserved from generation to generation, partly by word of mouth, partly in books. New investigations and corrections have not been added.

Superstitions have played an important rôle in our own medical science, but progress has mostly overcome this inheritance of the Dark Ages. Such, however, is not the case with the Chinese; superstitions have with them become a science, and they have built of them a structure with real Chinese consistency.

The Chinese physicians believe that the most important part of the body is the organ through which the soul enters it, the testicle in man, the uterus in woman, or, according to others, the kidneys, for male and female alike. The body consists of muscles, fat, arteries, skin, and bones. The functions and importance of the brain were not known formerly, while modern physicians classify the organ as the first of the intestines. The organs are divided into three classes: 1. The liver, the heart, the spleen, the lungs, and the genitals. 2. The gallbladder, the large and small intestines, the stomach, the urinary bladder, the kidneys, the testicles, and the three body cavities; these two classes constitute the intestines. 3. The twelve nerves, six to the arms and six to the legs. Each of these twelve nerves gives off three *yang* and three *yin*, which supply the organs of the body. The nerves consist of fine tubes, which, leading to all parts of the body, form the paths of travel for the soul.

The soul travelling from its point of entry to the centre of the body, which is situated at the junction of the nose and the upper lip, is sometimes thought to be in a gaseous, sometimes in a fluid form. From the centre of the body it supplies all parts with power and energy. The soul flows without interruption through the body, never returning to its place of entry. Where it flows more slowly or where it finds impediments, there will appear diseases. Anger makes the soul ascend quickly, happiness slowly, while fear makes it descend slowly, terror quickly; cold contracts the soul, heat expands it, and fatigue exhausts it.

There are points from the centre of the body two principal trunk arteries which supply the body and each with branches. One of the trunk arteries ascending vertically upwards to the cranium, and as

far as the end of the spinal column; the other vertically downward to the belly. The pulse can be felt in six places. Such is the traditional science of anatomy and physiology in old China.

### LOCO POISONING.

An interest not altogether devoid of mystery is connected with the loco poisoning of cattle on the plains east of the Rocky Mountains. The trouble is popularly attributed to the eating of certain plants by the cattle, plants known as loco weeds. The Bureau of Plant Industry of the United States Department of Agriculture has been investigating the subject, and Mr. C. Dwight Marsh, of the bureau, is satisfied that two plants, *Aragallus Lambertii* and *Astragalus mollissimus*, are capable of causing the disease known as loco poisoning. According to Mr. Albert C. Crawford, also of the bureau, the symptoms of loco disease may be produced in rabbits by feeding them with extracts of these plants. He attributes the poisonous action to the inorganic constituents, especially barium, at least as regards the plants collected at Hugo, Colorado.

Mr. Crawford remarks that there is a close analogy between the symptoms and lesions of barium poisoning and those that follow the administration of extracts of these plants. Small doses of barium salts, he says, may be administered to rabbits without apparent effect at first, but suddenly there are observed acute symptoms analogous to those reported as displayed by "locoed" cattle. Sulphates, especially magnesium sulphate, may be supposed to exert an antidotal effect, but it is doubtful how far they would be of service after the occurrence of anatomical changes. It seems that loco plants grown on certain soils contain no barium and are pharmacologically inactive. In testing loco plants for poisonous qualities, not only aqueous and alcoholic extracts should be used, but also extracts obtained by digesting the plants with the gastrointestinal ferments.

### THE PRESENT STATUS OF THE NEURONE DOCTRINE.

The neurone doctrine, as originally outlined by Waldeyer, like many other doctrines which have been promulgated by men of science, has led an uneven life. Alternately attacked and supported, it has seemed to come through the fierce light of opposition to gain a better foothold than before.

It is now only about seven years since Apathy's work on neurofibrils seemed to attack the principle at the very root of its being, and the onslaughts of

Bethe and Nissl from the morphological side added weight to the opposition, although it is now well recognized that these investigators did not make any serious inroads upon the doctrine. Hensen, in 1903, and Schultze, in 1905, however, to use Verworn's phrase in a recent address (*Medizinische Klinik*, January 24th) given by him on the neurone doctrine, "made serious breaks in the wall" when they gave evidence tending to show that the peripheral nerves might originate from a net or chain of cells rather than from the neuroblast, as originally laid down by His.

Swayed by the evidence of Schultze, Verworn's allegiance to the neurone doctrine suffered, as announced by him in the *Zeitschrift für allgemeine Physiologie*, vi, 1906, for the nucleus of the neurone doctrine lies in the conception that the body of the ganglion cell, with its nervous processes and dendrites, forms a cellular unit. The nerve prolongations, with their fibrillar differentiations as well as the dendrites, must be considered as a growth from the ganglion cell body and as constituting in their extension—i. e., the axis cylinder with its fibrillæ—the most important portion of the peripheral nervous system.

Should the cell chain origin be established, a radical viewpoint is reached that must modify our present conceptions of the neurone doctrine, but, as in times past, Ramón y Cajal comes to the rescue and shows, in a paper on the genesis of nerve fibres in the embryo (*Trabajos del Laboratorio de Investigaciones biológicas de la Universidad de Madrid*, Tomo iv, Madrid, 1906), that the old conception of His, which has been one of the most important foundations underlying the doctrine, is true, and that Schultze is incorrect in his deductions. Held, who at times has opposed the doctrine, supports Cajal in his studies, in a work on the histogenesis of the nerve fibres (*Anat. Anzeiger*, xxix), in which he traces the development of the neurofibrils from the protoplasm of the neuroblast, where they lie in a loose, turning mass, and develop into the nerve process as it grows out of the ganglion cell. Finally, from another source, an American investigator, Ross G. Harrison, in a series of studies on the transplanting of limbs and their bearing on the problems of the development of nerves (*Journal of Experimental Zoology*, 1907, 4), demonstrates with great definiteness that the cell chain theory of the origin of nerve fibres is not tenable. The question, then, again settles back to the original proposition that the nerve fibres are still to be considered as developments of the ganglion cell, and, in spite of the attacks of Apathy, Bethe, and Nissl, the essential feature of the neurone doctrine remains undisturbed.

## THE BUREAU OF ANIMAL INDUSTRY.

A modest pamphlet of sixty-nine pages constitutes the report of the bureau's work during the year 1907. Of course it is only a summary, the more elaborate reports on special subjects having been issued separately from time to time. We have frequently had occasion to mention the bureau's publications on matters of particular interest to the medical profession, and we have always found them commendable. In our opinion, the Bureau of Animal Industry of the United States Department of Agriculture is one of the most important agencies in advancing our knowledge of comparative medicine and therefore that of medicine in general.

## News Items.

**Changes of Address.**—Dr. Claude L. Wheeler, to 418 East Sixteenth street, Brooklyn (residence only).

**Manhattan State Hospital.**—Dr. William Seaman Bainbridge, of New York, has been appointed consulting surgeon to this hospital.

**The Pennsylvania State Board of Medical Examiners.**—Governor Stuart has appointed Dr. Winters D. Hamaker, of Crawford County, and Dr. M. P. Dickeson, of Delaware County, members of the State Board of Medical Examiners.

**Personal.**—Dr. T. Hewson Bradford, of Philadelphia, has retired from general practice and will devote his attention to medical insurance.

Dr. L. C. Ahlborn, of Waverly, West Virginia, is registered at the Philadelphia Polyclinic and College for Graduates in Medicine.

**The Harvey Society Course of Lectures.**—The seventh lecture in this course will be delivered by Professor Otto Folin, of Harvard Medical School, at the New York Academy of Medicine on Saturday evening, February 22d, at 8:30 p. m. The subject is Problems of Chemistry in Hospital Practice.

**Buffalo Academy of Medicine.**—A meeting of the Section in Pathology was held on Tuesday evening, February 18th. Dr. James A. Gibson read a paper entitled Some Observations on the Sphenoidal Sinus, and presented specimens, and Dr. A. L. Benedict gave a demonstration of a new method of determining urinary acidity.

**For the Suppression of Tuberculosis and Typhoid Fever in New York State.**—Dr. Eugene H. Porter, Health Commissioner of New York State, has asked the Legislature for an additional appropriation of \$75,000 to carry on the work of the campaign against tuberculosis, and \$30,000 to inspect local water supplies with a view to stamping out typhoid fever.

**The Section in Otolaryngology and Laryngology of the College of Physicians of Philadelphia** held a meeting on Wednesday evening, February 19th. Dr. George Morley read a paper entitled A New Method of Treating the Ethmoid and Sphenoidal Cavities and Orbit Operation, and Dr. J. L. Goodale, of Boston, delivered an address on the relation of Local Treatment to Acute Inflammation of the Throat from the Standpoint of Pathology. The Honorable Mr. Folger presided.

**Hartford, Conn., Medical Society.**—The Surgical Section will meet on Monday evening, February 24th, at 9 o'clock. Dr. A. J. White will read a paper entitled Peritonitis, with Infection from a Ruptured Appendix, and Dr. M. A. Bailey will report a case of Cellulitis Treated by Scarification. Dr. Oliver C. Smith will give a report of the case of a patient who had been treated at the Drs. Mayo, and the Chicago hospitals will be discussed by Dr. J. C. Smith and Dr. R. L. Smith.

**The Northern Medical Association of Philadelphia,** at its semi-monthly meeting, held on Friday, February 14th, had a symposium on gastric ulcer. Dr. A. O. J. Kelly spoke on the pathology, ætiology and symptomatology; Dr. Albert Bernheim spoke on the medical treatment, and Dr. William L. Rodman spoke on the surgical treatment.

**West End Medical Society, New York.**—The first regular meeting of this society for the year 1908 will be held at the residence of Dr. Theron W. Kilmer, 165 West Eighty-fifth street, on Saturday evening, February 22d, at 8:15 o'clock. Dr. Henry L. Shively will read a paper entitled The Association of Tuberculosis of the Lungs with Diabetes Mellitus.

**Rochester, N. Y., Academy of Medicine.**—The regular meeting of the Section in General Medicine, which includes neurology, psychiatry, materia medica, and therapeutics, was held on the evening of Wednesday, February 19th. Dr. William S. Ely read a paper on Human Asymmetry; Dr. Robert G. Cook read a paper on Acute Anterior Poliomyelitis; and Mr. John W. Radu gave a demonstration on the Action of the Valves of the Heart.

**Examination for Internes at the City Hospital.**—An examination will be held on March 27th and 28th to secure internes for the house staff of the City Hospital. The hospital has a capacity of about eight hundred beds, comprising all branches of medicine, and the term of service is eighteen months. All applications should be addressed to the chairman of the Examination Committee, Dr. Smith Ely Jelliffe, 64 West Fifty-sixth street, New York.

**Medical Society of the County of Kings, N. Y.**—A meeting of the Section in Pediatrics was held on Friday evening, February 21st. Dr. R. M. Beach presented a case of Enlarged Thymus cured by the x ray, and Dr. A. J. Summer presented a case and specimen of foetal rickets. Dr. Maurice Packard, of New York, read a paper on the Treatment of Pneumonia in Children, and Dr. John F. Crawford read a paper entitled A Review of English Pædiatric Literature.

**Syracuse, N. Y., Academy of Medicine.**—A regular meeting of this academy was held on Tuesday evening, February 18th. The programme included the following papers: Ectopic Gestation, by Dr. W. H. Maynard; Some Unusual Experiences in Scarlet Fever, by Dr. Robert H. Phelps, of Norwich; and The Early Recognition of Tuberculous Bone and Joint Disease in Children, by Dr. E. J. Wynkoop. Dr. C. E. Coon illustrated Dr. Wynkoop's paper with Röntgen ray lantern slides.

**Saratoga Springs, N. Y., Medical Society.**—A symposium on pleurisy was held by this society at its February 21st meeting. Dr. A. J. Leonard read a paper on the Ætiology and Pathology of Pleurisy, which was discussed by Dr. G. S. Towne; Dr. E. A. Palmer read a paper which dealt with the symptoms and diagnosis, and Dr. J. T. Humphrey read a paper on the treatment. Dr. F. J. Resseguie discussed Dr. Palmer's paper and Dr. D. C. Moriarty discussed Dr. Humphrey's paper.

**The Delaware County, Pa., Medical Society** held its regular monthly meeting in Chester, Pa., on Thursday, February 13th. Dr. John M. Swan, instructor in tropical medicine in the Philadelphia Polyclinic and College for Graduates in Medicine, addressed the society on the Diagnosis of Malaria. A demonstration of the plasmodium malariae was arranged. The president of the society, Dr. Frank J. Evans, of Chester, entertained the society at supper.

**Assistant Surgeons Wanted for the Medical Corps of the Army.**—It is announced that there are twenty-three vacancies in the Medical Corps of the Army, and to secure assistant surgeons to fill these vacancies examinations will be held in Massachusetts and New York at various points throughout the country where boards can be convened. Applicants must be citizens of the United States, must be between twenty-two and thirty years of age, graduate from a medical school in the United States, and shall have had at least one year's hospital training or its equivalent.

**The Medical Society of the Borough of the Bronx** held a meeting on February 12th. The evening was devoted to a symposium on Influenza, the following papers being read: The Diagnosis and Treatment of Influenza, by Dr. Thomas J. Dunn; Influenza in Children, by Dr. A. F. Brugman; the Nose and Throat Complications of Influenza, by Dr. Charles Graef; the Ear Complications of Influenza, by Dr. John B. Rae; and Influenza in Its Relation to the Nervous System, by Dr. William M. Leszynsky. The general discussion which followed the reading of the papers was opened by Dr. G. H. E. Starke.

**New York Academy of Medicine.**—At a stated meeting to be held on Thursday, March 5th, at 8:30 p. m., under the auspices of the Section in Medicine, there will be a discussion of the subject of Nutrition in Typhoid Fever. A paper on Metabolism and Diet in Typhoid Fever will be read by Dr. Warren Coleman and Dr. P. A. Shaffer, and Dr. Morris Manges will read a paper entitled The Limitations of Liberal Feeding in Typhoid Fever. Among those who will take part in the discussion are Dr. Graham Lusk, Dr. C. G. L. Wolf, Dr. W. Gilman Thompson, Dr. Egbert La Fevre, Dr. T. C. Janeway, and Dr. James Ewing.

**The Eastern Medical Society of the City of New York** held a meeting on Friday, February 14th, the evening being devoted to a symposium on Diseases of the Bones and Joints. Dr. Leo Buerger read a paper on Bone Sarcomata; Dr. Martin W. Ware gave a stereoscopic demonstration of radiograms of Syphilitic Bone Disease; Dr. P. W. Nathan read a paper on Mechanical Treatment of Bone and Joint Tuberculosis; Dr. Willy Myer read a paper on Bier's Hyperæmic Treatment in Tuberculous Affections of the Joints; and Dr. Joseph Weiner read a paper on General Considerations of Bone and Joint Tuberculosis.

**Scientific Society Meetings in Philadelphia for the Week Ending February 29, 1908.**—*Monday, February 24th*, Mineralogical and Geological Section, Academy of Natural Sciences; Society of Normal and Pathological Physiology, University of Pennsylvania. *Tuesday, February 25th*, Philadelphia Neurological Society. *Wednesday, February 26th*, Philadelphia County Medical Society. *Thursday, February 27th*, Pathological Society; Entomological Section, Academy of Natural Sciences; Section Meeting, Franklin Institute. *Friday, February 28th*, South Branch, Philadelphia County Medical Society; Northern Medical Association.

**Charitable Bequests.**—By the will of George W. Warner, the Orphans' Home and Asylum for the Aged and Infirm of the Evangelical Lutheran Church of Germantown, the Northern Home for Friendless Children, the Home for Aged and Infirm Colored Persons, and the Pennsylvania Home for Blind Women, become contingent legatees to the extent of \$2,500 each. The Pennsylvania Hospital, the Episcopal Hospital, and the Pennsylvania Institution for the Instruction of the Blind are also contingent legatees.

By the will of Catherine Cullin, St. Joseph's Home for Homeless Boys and St. Francis's Industrial School, Philadelphia, receive \$100 each. The Catholic Home for Destitute Children receives \$50.

**The Mortality of Chicago.**—According to the report of the Department of Health for the week ending February 8th, there were during the week 747 deaths from all causes, as compared with 783 for the corresponding week in 1907. The annual death rate was 17.08 in 1,000 of population. The principal causes of death were: Apoplexy, 14; Bright's disease, 40; bronchitis, 351; consumption, 171; cancer, 33; convulsions, 8; diphtheria, 10; heart diseases, 57; influenza, 43; intestinal diseases, acute, 42; measles, 3; nervous diseases, 25; pneumonia, 149; scarlet fever, 10; suicide, 7; typhoid fever, 7; violence, other than suicide, 30; whooping cough, 5; all other causes, 149. More than one-third of the total numbers of deaths were caused by consumption, pneumonia, and bronchitis.

**Vital Statistics of New Jersey.**—The monthly statement of vital statistics issued by the Board of Health of the State of New Jersey for the month of January shows that there were 411 deaths from pneumonia during that month, which is an increase of 195 over the preceding month and 79 over the corresponding month for last year. Pulmonary tuberculosis was the cause of 284 deaths, which is 30 less than the average monthly death rate from this

disease. These two diseases are responsible for more deaths than any other single disease reported. During the month 1,000 bacteriological examinations have been made, 514 of which were from suspected cases of diphtheria, 296 from tuberculosis, 171 from typhoid fever, and 9 from malaria. Out of 428 specimens of food and drugs examined, 89 were below the standard, 339 above.

#### Infectious Diseases in New York:

*We are indebted to the Bureau of Records of the Department of Health for the following statement of new cases and deaths reported for the two weeks ending February 18, 1908:*

	February 11.—		February 25.—	
	Cases.	Deaths.	Cases.	Deaths.
Tuberculosis pulmonary	339	268	349	225
Diphtheria	42	55	371	46
Measles	1,163	25	1,164	26
Scarlet fever	744	52	756	55
Smallpox	1	..	4	..
Varicella	162	..	155	..
Typhoid fever	21	3	20	5
Whooping cough	11	..	9	5
Cerebral meningitis	13	6	7	8
Totals	27,6	553	2,772	379

#### Society Meetings for the Coming Week:

**MONDAY, February 24th.**—Medical Society of the County of New York.

**TUESDAY, February 25th.**—New York Medical Union; New York Dermatological Society; Metropolitan Medical Society of the City of New York; Buffalo Academy of Medicine (Section in Obstetrics and Gynecology).

**WEDNESDAY, February 26th.**—New York Academy of Medicine (Section in Laryngology and Rhinology); New York Surgical Society.

**THURSDAY, February 27th.**—New York Academy of Medicine (Section in Obstetrics and Gynecology); New York Celtic Medical Society; Brooklyn Pathological Society; Hospital Graduates' Club, New York; Brooklyn Society for Neurology.

**FRIDAY, February 28th.**—New York Clinical Society; New York Society of German Physicians; Academy of Pathological Sciences.

#### The Medical Jurisprudence Society of Philadelphia.

The seventy-fourth stated meeting of this society, which was held on Monday evening, February 17th, was devoted to a symposium on the Public's Gain by State Control of Medical Practice. Papers were read as follows: What People Have Gained Through the Present State Medical Examination Law, by Dr. John B. Roberts; What the Public Gains by a Single Examining Board System for Lawyers, by Thomas W. Barlow, Esq.; Newspaper Publicity Necessary to Warn the People as to Insufficient Protection by the Present Multiple Medical Examining Boards Plan, by Mr. Edward Sterling; Some Facts Relating to Medical Education in the United States Discovered and Demonstrated by the Operation of the Act of Assembly Regulating Practice in Pennsylvania, by Dr. Henry Beates; Consolidation of Multiple Medical Examining Boards into a Union or One Board Plan Required to Give Full Protection, by Mr. Adolph Eicholz. A general discussion followed.

**The U. S. Pharmacopœia as a Textbook in Medical Schools.**—Professor Joseph P. Remington, chairman of the Committee of Revision of the U. S. Pharmacopœia, recently called an informal conference of the medical teachers of Philadelphia, at which the following resolution was passed:

*Resolved*, That it is of the utmost importance for accuracy in prescribing, and in the treatment of disease, that students of medicine be instructed fully as to those portions of the U. S. Pharmacopœia which are of value to the practitioner, and that members of the medical profession be urged to prescribe the preparations of that publication, and further, that this resolution be forwarded to the medical and pharmaceutical journals, and to the teachers of medicine and therapeutics in the United States.

Among those who attended the conference were Dr. James Tyson, Dr. John H. Musser, Dr. John Marshall, Dr. Horatio C. Wood, Jr., Dr. J. W. Holland, Dr. Hobart Amory Hare, Dr. James C. Wilson, Dr. E. Q. Thornton, Dr. John V. Shoemaker, Dr. Seneca Egbert, Dr. M. C. Huch, and Dr. J. Newton Smith.

**The Health of Philadelphia.**—During the week ending January 25, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Malarial fever, 2 cases, 0 deaths; typhoid fever, 87 cases, 21 deaths; typhus, 1 case, 0 deaths; chickenpox, 57 cases, 0 deaths; diphtheria, 54 cases, 7 deaths; cerebrospinal meningitis, 5 cases, 5 deaths; measles, 122 cases, 4 deaths; whooping cough, 12 cases, 0 deaths; pulmonary tuberculosis, 11 cases, 62 deaths; pneumonia, 90 cases, 98 deaths; erysipelas, 16 cases, 3 deaths; German measles, 1 case, 0 deaths; cancer, 28 cases, 25 deaths; mumps, 10 cases, 0 deaths; tetanus, 1 case, 1 death; hydrophobia, 1 case, 1 death; anthrax, 1 case, 1 death. The following deaths were reported from other transmissible diseases: Tuberculosis other than tuberculosis of the lungs, 5 cases; puerperal fever, 2 cases; diarrhoea and enteritis, under two years of age, 14 cases; septicemia, 1 case. The total deaths numbered 573 in an estimated population of 1,532,738, corresponding to an annual death rate of 19.40 in 1,000 of population.

**A New International Journal of Epilepsy**, to be called *Epilepsia*, is about to be launched as an international quarterly which will be devoted to the study and treatment of epilepsy. It is announced that this journal will be under the patronage of Dr. W. Bechterew, Dr. O. Binswanger, Dr. C. Hughlings Jackson, Dr. L. Luciani, Dr. H. Obersteiner, and Dr. F. Raymond. The editorial staff includes Dr. H. Claude, of Paris; Dr. A. Turner, of London; Dr. L. Bruns, of Hanover; Dr. W. P. Spratling, of Sonyea; Dr. J. Donath, of Budapest, who will be the active editor for the first year; and Dr. L. J. J. Muskens, of Amsterdam, who is the secretary. Among the collaborators and assistants are the following: Apelt, Grainger Stewart, Lejonne, Maes, Perusini, Southard, Agostini, Aschaffenburg, Alt, Alzheimer, Bastein, Batten, Brandos, Bruce, Ferrier, Gowers, Haskovec, Van Hamel, Hebold, Heilbronner, Henschen, Horsley, Jørgensen, Jelliffe, Kocher, Kowalewsky, Krause, Kure, Lewandowsky, Maxwell, Meyra, Nonne, Oppenheim, Probst, Cajal, Redlich, Stertz, Jurkel, Voisin, Weber, Salomonson, Wiersma, Winkler, and Ziehen. The official languages will be English, German, and French. Further information concerning this new publication may be obtained from the collaborators or from the *Journal for Nervous and Mental Disease*, New York.

**Coroners' Cases in Brooklyn During the Year 1907.**—According to the report of the Board of Coroners, the total number of cases that came within the jurisdiction of the coroners during the year 1907 was 3,474. Of these 1,810 were sudden deaths, or cases where medical attendance was lacking, 1,288 were deaths from some form of violence, and 376 were still births. The deaths by violence are classified as follows: Suicides: By illuminating gas, 75; pistol shot wound, 64; knife wounds, 14; poison, 34; strangulation, 36; jump from height, 6; drowning, 3; jump in front of "L" train, 2; total, 234. Homicides: By pistol shot wounds, 45; knife wounds, 10; blow from club, fist, etc., 18; poison, 1; illuminating gas, 3; total, 77. Railroads: By trolley, 102; elevated or motor trains, 26; steam railroads, 19; shock, third rail, 2; total, 149. By wagons, trucks, etc., 70; automobiles, 8; falls from windows, stoops, etc., 203; by being crushed, 60; kick of horse, 2; suffocation, gas, accidental, 82.

tion, children in bed, 6; accidental shooting, 3; accidental poison, 24; accidental drowning, 114; electricity (live wire), 6; abnormality, 1; burns, 1; head trauma, 10; bone, 1; eye, 1; muscle, 1; as follows: Exposure, 7; rabies, 7; vaccine poison, 2; explosion, 1, and choked while eating, 1.

**Vital Statistics of New York State.** During the year 1907 there were 20,743 deaths reported. Of these 10,422 were males, 10,321 were females, and 1,000 were children under 15 years of age. There were 10,000 deaths among persons of Indian and/or Chinese descent. The average length of life in the State was 46.8, and for New York City 50.2. The total number of deaths reported in 1907 was 14,442, or 14.4 per 1,000 of the population, as compared with 14.7 in 1906. The number of deaths in 1907 was 26,000 males and 27,426 females. Of the reported deaths in 1907, 14,900 were from infectious diseases, the largest number from any one disease group. There were 1,008 deaths from heart disease, and 1,006 from pneumonia. There were 1,668 deaths from typhoid fever, an increase of 100 over the previous year, 992 deaths from measles, a decrease of 374 from the previous year, 1,000 deaths from scarlet fever,

fever, an increase of 330 over the previous year; 2,600 deaths from diphtheria, an increase of about 100 over the previous year. There were 2,377 deaths from influenza, 483 from erysipelas, 222 from cerebrospinal meningitis, 6,400 from cancer, 14,668 from diseases of the nervous system, and 16,893 from diseases of the circulatory system. The deaths under one year of age were 27,957; from one to five years of age, 12,142; from five to ten years of age, 3,249; from ten to twenty years of age, 5,206; from twenty to forty years of age, 24,830; from forty to sixty years of age, 29,539; from sixty to eighty years of age, 34,516; and over eighty years of age, 9,838.

**The Health of the Canal Zone.**—During the month of December, 1907, the total number of deaths in the Canal Zone was 263, in a population of 110,713, corresponding to an annual death rate of 28.50 in 1,000 of population. There were 6 deaths from typhoid fever, 1 from relapsing fever, 33 from clinical malaria, 2 from malarial cachexia, 3 from hæmoglobinuric fever, 3 from amebic dysentery, 1 from clinical dysentery, 5 from beriberi, 26 from pulmonary tuberculosis, 2 from other forms of tuberculosis, 2 from syphilis, 2 from cancer, 3 from tetanus, 4 from bronchopneumonia, 28 from pneumonia, 20 from diarrhœa and enteritis under two years of age. There were 14 deaths among the white employees, 5 of which were natives of the United States. There were two deaths among the white American workmen, one from typhoid fever, one from aggradarum, and one from capillary bronchitis. It must, of course, be understood that the annual death rate of 28.50 above recorded includes the entire population of the Canal Zone as well as of Panama and Colon. The death rate in American territory was 21.67 in 1,000 of population; that in Panama and Colon, 36 in 1,000 of population.

**Meetings of Sections of the New York Academy of Medicine.**—At a meeting of the Section in Ophthalmology, held on Monday evening, February 17th, the following papers were read: When and How Shall We Use Cycloplegics in Refractive Work? by Dr. Alexander Duane. Report of a Case of Traumatic Rupture of Descemet's Membrane, by Dr. E. B. Coburn; Unguentum Hydragryi Oxidi Flavæ. Improved, by Dr. T. R. Chambers.

18th. Dr. H. W. Berg read a paper on General Phlebotomy and Dr. D. M. Kaplan read a paper entitled The Life History of the Malarial Parasite. Dr. G. R. Satterlee reported a case of Pernicious Malaria with Autopsy; Dr. T. C. Janeway reported a case of Rapidly Fatal Diabetes; Dr. L. A. Conner reported a case of Rapidly Fatal Diabetes with Unusual Cerebral Symptoms; and Dr. C. N. B. Camac reported a case of Diabetic Coma under Alkaline Treatment.

The Section in Orthopaedic Surgery met on Friday evening, February 21st. The general topic for discussion was Fractures Complicating Joints, the following papers being read: Epiphyseal Fracture of the Hip, by Dr. Royal Whitman; Surgery of Fracture Dislocations of the Shoulder, by Dr. Carleton P. Flint; and Fractures Complicating the Elbow Joint, by Dr. C. S. Cole. Dr. William C. Lusk presented a case of Supracondylar Fracture of the Humerus; Dr. Reginald H. Sayre presented a case of Fracture of the Anatomical Neck of the Humerus; Dr. Fred H. Albee presented two cases of Epiphyseal Fracture of the Upper End of the Humerus, showing the method of reduction; and Dr. John Carling presented two cases of Fracture of the Carpus.

The Southern Laryngology and Rhinology will meet on Wednesday, February 26th, at 8:15 p. m. The following program has been arranged: Dr. Robert C. Myles will present a case of Osteochondroma of the Septum, with Extensive Absorption of the Cristiform Plate, and Dr. J. W. Gleitsmann will present a case of Excision of Tuberculous Infiltration of the Epiglottis. There will be a symposium on Atrophic Rhinitis, including Ozena. Papers on the subject will be read as follows: A Consideration of the Head Throat, by Dr. J. M. H. Smith, of New York; Dr. Clement F. Theisen, of Albany, N. Y.: The Pathology of Atrophic Rhinitis, with Ozena, by Dr. D. Braden Kyle, of Philadelphia; and The Treatment of Atrophic Rhinitis, including Ozena, by Dr. George L. Kyrle, of New Bedford, Mass., and Dr. Robert C. Myles. The subject will be discussed by Dr. Francke H. Bosworth, Dr. Clarence C. Ross, Dr. D. Brayton, Dr. James F. New, and Dr. J. M. H. Smith.

## Pith of Current Literature.

## THE BOSTON MEDICAL AND SURGICAL JOURNAL.

February 13, 1908.

1. The Control of the Lymphatics in Injections of the Extremities, By HERBERT L. BURRELL.
2. On the Value of Malachite Green Media in Distinguishing Typhoid and Colon Bacilli, with the Description of a New Method for Isolating Typhoid Bacilli from Fæces, By F. W. PEABODY and J. H. PRATT.
3. Observations on Six Cases of Acute Perforating Ulcer of the Duodenum, By E. G. CODMAN.
4. The "Optometrist" and His "Colleges," By JOHN C. BOSSIDY.

2. **Malachite Green Media in Distinguishing Typhoid and Colon Bacilli.**—Peabody and Pratt remark that the cultural methods for the distinction of the typhoid bacillus from the other bacteria accompanying it in fæces, earth, and water, may be divided into two general classes. In those of the first attempts have been made to produce a characteristic typhoid growth—whether of form or of color. In the second, the object is to favor the growth of the typhoid bacillus, and to inhibit the growth of all other organisms, and more especially of the colon bacillus. The ideal medium for isolating the typhoid bacillus from the stools would be one upon which no other microorganism could develop. In 1903, before the Aertzlicher Verein, of Greifswald, Loeffler first demonstrated the use of malachite green culture media. He showed that the addition of a definite amount of this dye to ordinary agar favored the growth of typhoid bacilli, but inhibited the growth of colon and many other intestinal bacteria. Our authors have made experiments with malachite green media. The general results of these experiments has led them to hold the malachite green media in high esteem. They are not ideal, for their action is not absolutely specific; while they inhibit the growth of the colon bacillus, the microorganism most likely to be confounded with the typhoid bacillus, there are other bacteria which flourish in them. Furthermore, as Jorns and Klinger clearly showed, malachite green checks somewhat the development of the typhoid bacillus. It is, nevertheless, true that the discovery of the action of malachite green is a step forward in the search for a perfect differential culture medium. They have found it comparatively easy to make a medium on which the typhoid bacillus will grow and on which the colon bacillus will not grow. While it is true that various preparations of malachite green differ in their action, it is a simple process to determine the strength of solution to be used, and the proper reaction of the medium for the given preparation. The malachite green bouillon method is not only more economical in time and money than that of Lentz and Tietz, but in the author's laboratory has yielded better results.

3. **Observations on Six Cases of Acute Perforating Ulcer of the Duodenum.**—Codman gives the following points which would make him suspicious of duodenal ulcer instead of appendicitis: 1. Onset of pain more sudden and violent and more initial shock. 2. A contracted concave boardlike abdomen. This seems to be very characteristic,

though some cases of appendicitis have it, too. 3. Tympany over the normal area of liver dullness. This is by no means the rule, but when present is almost diagnostic. Gas may not always be noticed when the peritoneum is opened. 4. The vague symptoms of duodenal ulcer elicited by careful questioning. 5. Most of the patients are males between twenty and forty years. 6. Location of tenderness and pain is very deceptive. Of interest are also the following remarks of the author: If perforated ulcer is suspected, it is well to be sure that small, curved, round needles are on hand, for one is much embarrassed with straight needles in suturing the perforation. Make high appendix incision and examine condition of appendix first. Take it out if necessary, to be sure of the mucosa. If the appendix is not perforated or gangrenous, carry incision up rectus high enough to see whether there is fibrin about the pylorus. If there is, carry incision up to actual margin of ribs. One needs plenty of room to do suture quickly. One obtains the best view of the duodenum by pulling the gallbladder out with one hand and hepatic flexure down with the other. Most ulcers are easy of access. Suture the ulcer before washing out the abdomen. Unless the ulcer is large and indurated or extends beyond the pylorus to the stomach, or there is stenosis of the pylorus, or the history shows severe pain and distress in the past, gastroenterostomy should not be performed. Finally, the author asks the following questions, which he would like to have answered: Why is duodenal ulcer a male disease? What evidence is there to show that these small ulcers are intractable in healing? Why may the persistent symptoms not be due to the cause (duodenal stasis) or the result (periduodenal adhesions)? Can perforation into the pancreas cause a leakage of pancreatic juice into the intestine at the wrong time? Why may not the alkaline duodenal secretions be responsible for some of the pain attributed to acid gastric secretions?

1. The Problems of Sanitation, By EDWIN O. JORDAN.
2. Pregnancy as an Etiological Factor in Dental Disease, By JAMES E. POWER.
3. Physical Diagnosis: Urgent Need of Revision, By J. H. TYNDALE.
4. Simultaneous Sphygmomanometric Pressures as Modified by Postures, By A. H. SANFORD.
5. A Case of Hair Ball in the Stomach, By J. B. HARVEY.
6. Policephalitis Superior; Its Causation, Clinical Course, and Termination, with a Report of Six Cases, By WARD A. HOLDEN and JOSEPH COLLINS.
7. A Report of One Hundred Consecutive Perineal Prostatectomies Without a Death. With Remarks on the General Decrease in the Mortality of Prostatic Operations in Recent Years, By HUGH H. YOUNG.
8. Experiments on Subconscious Ideas, By E. W. SCRIPTURE.
9. Enuresis Following Prostatectomy. Report and Analysis of Eleven Cases, with Recommendations as to Treatment, By GRANVILLE MACGOWAN.
2. **Pregnancy as an Etiological Factor in Dental Disease.**—Power reminds us of the importance to keep the oral cavity in good condition during pregnancy. He remarks that since the physician is responsible directly, and the dentist indirectly, for the salvation of the teeth during the time the pregnant woman is in their charge, their

first duty is to impress on the mind of the patient how dependent is the entire system on the cleanliness of the oral cavity. The dentist should make a thorough examination, and should restore all the diseased teeth to a normal condition, so far as this is possible. The condition of the patient will regulate to a large degree the kind of material to be used in restoring the teeth. It is the author's custom to consider very carefully the physical state of the patient, whether she is irritable or not, how many months she has been pregnant, etc. He gives appointments to such patients about noon, as he found their condition is best at that time. The reservation of time is always short, never longer than one hour, and many times less, and he relies on his personal judgment, rather than that of the patient, as to her capacity for enduring the strain which is, to some degree at least, associated with dental operations, especially at this time. He extracts all broken down roots, after first subjecting parts to a local anæsthetic. The next important step is to clean the mouth thoroughly, and then arrange for the patient to make a monthly visit to the office, or for the dentist to make one to her home. This accomplishes two important objects: First, it causes the patient to take good care of the mouth, because she knows it is going to be inspected, and, second, one can observe any unlooked for conditions, and correct them immediately, as well as assist the patient in keeping the mouth clean. In his observation, the degree of morning sickness and the degree of dental caries are very closely related. During the day he advises the rinsing of the mouth with a solution of sodium bicarbonate or milk of magnesia every four hours, each mouthful of the solution to be held one full minute by the watch. In some severe cases he prescribes the use of tablets whose formula is sodium bicarbonate, with directions to allow it to dissolve after having placed it between the cheeks and the first and second molar teeth, in the region of Steno's duct. There is thus a remote possibility of any trouble of a dental nature occurring during the most critical period of pregnancy. The treatment of toothache or of an abscessed tooth is one of the conditions which the dentist must consider. In case of toothache he advocates the extraction of diseased teeth, treatment of which might be attended with pain sufficient to affect the life of the embryo and possibly also that of the mother in this condition. Under anæsthesia, if possible local, and with modern technique, it can be safely done. It is advisable to avoid it at times corresponding to the menstrual period on account of the greater risk than of abortion. Great care should be exercised in determining the source of dental pain, as often the source of pain appears more than manifest itself and treatment or extraction of an apparently aching tooth may complicate rather than simplify the case.

**4. Simultaneous Sphygmomanometric Pressures as Modified by Postures.**—Sanford concludes from his experiments that by carefully noting the changes in the pulse as compression is being applied, not only the point of obliteration is noticeable, measuring the systolic pressure in the vessel, but also the point of diminution of the amplitude of the pulse in the diastolic pressure, can

be observed, and, furthermore, in many instances, a marked oscillation occurs in the mercury column at and above the point of diastolic pressure. Posture affects both systolic and diastolic pressure. There is an increase of pressure in the arm in changing from the erect to the sitting, supine, and the head down positions, and at the same time a corresponding marked decrease in the pressure in the lower extremity. These changes of blood pressure are attended with a marked decrease in pulse rate. The pulse pressure, or difference between diastolic and systolic pressures, increases in the arm and decreases in the thigh as the body changes from the erect to the sitting, supine, and Trendelenburg postures. In the sphygmomanometer we have a convenient method of applying a known amount of compression to a limb, and thus may make of it a therapeutic instrument in methods of passive hyperæmia treatment.

**6. Poli-encephalitis Superior.**—Holden and Collins state that in regard to the ætiological and pathological contributions to our knowledge of the disease, the most important are, first, that the same causes that are responsible for inflammation of the gray matter in other parts of the central nervous system are responsible for this disease. Acute infections, such as influenza, pneumonia, and diphtheria, have all been accused of being the cause of the disease and a very strong case made out against them. It is not only infections, however, in whose wake it follows, for cases have been reported which seemed to show that lead, oxide of carbon, sulphuric acid, etc., were responsible factors. Study of the central nervous system of many of these cases in which a post mortem examination was held has shown that in a number of them the structural changes are slight and entirely out of proportion to the severity of the symptoms that existed. Indeed, in some instances no lesion adequate to account for the symptoms or the fatal termination of the disease was found. These cases are looked on as analogues of æsthetic bulbar paralysis (bulbar paralysis without anatomic foundation), in which it is supposed that several levels of the different segments of the central nervous system are so overwhelmed by some toxic agent that they become functionless to a certain degree, and in some instances wholly so. It is supposed that the injurious agency, whatever it may be, is not of sufficient severity to cause discernible morbid changes in the cells.

**9. Enuresis Following Prostatectomy.**—MacGowan, from his experience, is of the opinion that after removal of extremely large growths bladder control sometimes comes slowly, and a condition of enuresis, either partial or total, will exist for from six months to a year, and, perhaps, always. This condition, though lamentable, improves with time, and is apt to be best at night. There is no surgical remedy, if the operation has been complete. But he recommends, wherever the leakage has lasted for six months that various neural, anæsthetic, and mechanical measures be used, and if any remaining intraurethral or intravesical nodules be found that they be removed. There are some cases, however, not uncommon, which cannot be removed. Such cases should not be disturbed until the comfortable use of the bladder becomes impossible.

Through these a permanent groove or furrow must be made, preferably by the cautery apparatus of Chetwood. They will always leak. Where enuresis follows the imperfect removal of a small, hard prostate, the only remedy is the partial section of the fibrous ring and the prostate on its floor, and removal of the prostate, together with the nonresilient scar tissue. In such cases patients will then slowly regain control and be well people. If following a prostatectomy, usually perineal, and where the prostate has been only of moderate size, there is enuresis, and a careful rectal examination fails to show the presence of an intracapsular growth of palpable size, overlooked at the time of the operation, a careful examination of the posterior urethra and bladder, with suitable optical instruments, has sometimes revealed the presence of small tumors of glandular tissue hanging or pressing into the vesical outlet, preventing its closure, and the removal of such tumors by a second operation has resulted in a cure of the condition.

#### MEDICAL RECORD.

February 15, 1908.

1. What Shall We Do with Far Advanced Cancer of the Large Bowel? By R. C. COFFEY.
2. Sanitation of the Canal Zone, By COLONEL WILLIAM C. GORGAS.
3. A Method of Milk Production. By CHARLES E. NORTH.
4. The Importance of Correct Diagnosis in Diseases of the Eye Is the Chief Reason Why Opticians Should Not Prescribe Glasses, By A. EDWARD DAVIS.
5. Phthisis in Outdoor and Indoor Life and in Isolated and Cosmopolitan Races, By NORBURN B. JENKINS.

#### 1. For Advanced Cancer of the Large Bowel.

—Coffey quotes eleven cases of far advanced cancer of the large bowel operated on by Willy Meyer, sixteen by Jonas, and eleven by himself. He concludes that far advanced obstructive cancer, not pathologically extensive, should always be excised. For extensive growths producing obstruction, excision may be used in certain cases with hope of relief, if not cure, but a larger percentage are best treated by some form of enterostomy or colocolostomy or colostomy. Extensive growths with marked cachexia and producing no obstruction should be treated by meeting the medications with curetting, late colostomy, etc. In answer to those who say, "Let these far advanced cases die and get out of their misery," the author understands our duty to be: (1) Use desperate and radical means to remove cancers in all cases where there is a reasonable hope of cure, either temporary or permanent. (2) In irremovable cases, perform such operations as will prolong life or add to the comfort of the patient.

3. A Method of Milk Production.—North says that the use of sterile covered pails and sterile milk cans by the ordinary farmer will immensely reduce the bacteria in his milk, even though no other sanitary precautions are taken. The dairy house, where washing and sterilizing of utensils and cooling and bottling of milk are done, may be at a distance of several miles from the cow stable without materially increasing the bacterial count, provided the milk is delivered at the dairy house within one hour after milking. Five cents per quart to the farmer will pay him for his trouble of milking in a

sanitary way and for making two deliveries a day. In many instances it would compensate him for keeping his herd free from tuberculosis. Increase the functions of the creamery, so that it becomes a washing and sterilizing plant for all the milking pails and milk cans of all the farmers contributing milk to it. Substitute cover milk cans or "pailcans" for the wide open milking pails now in use. Let the creamery do all the cooling and bottling of milk. Take the cooling out of the hands of the farmer. Let the milk dealer pay the farmer five cents per quart for such milk, and the public pay the milk dealer ten cents per quart for milk delivered in the city. High prices for certified milk is due to the expense at the dairy house. Concentration of operations at the creamery for a large number of farmers would be business economy, and would likewise eliminate many sources of contamination.

5. Phthisis in Outdoor and Indoor Life and in Isolated and Cosmopolitan Races.—Jenkins remarks that indoor races, in centuries of environment favorable to tuberculosis, in order to survive have probably acquired especial aggressiveness against or resistance to the disease. This immunity has been acquired, since individuals and finally races, favored through variation and by heredity with resistance would escape or overcome the disease and in turn leave more strongly immunized offspring as racial survivors. On the other hand, individuals without resistance to the disease would tend to perish without offspring, thus eliminating the susceptible. In centuries of indoor contact with tuberculosis, phagocytes, enzymes, and opsonins may have acquired power or become trained to resist and overcome the disease. Again, the body may have selected superior tissue or certain as yet undiscovered bactericides with which to resist or arrest the disease. Such means of defense would be transmitted to the body's offspring, and thus not only the body itself, but also its successors would survive, even in the unfavorable environment of indoor life. Outdoor races in their natural environment probably escape tuberculosis without the especial resistance which indoor peoples require in order to survive contact with tuberculosis in indoor life. The agents which destroy, expel, transfer, or absorb the *Bacillus tuberculosis* may be partially or entirely absent, may be latent or rudimentary, may be in inherent or acquired weakness from centuries of nonuse or may be unable to combat unaccustomed infection and are inactive when tuberculous invasion occurs. Outdoor races, when in unchanged environment and at the same time exposed to the *Bacillus tuberculosis*, may resist the disease more successfully than when exposed to both the disease and the more or less unaccustomed environment of civilization. Biologically speaking, in tuberculosis of immune races, pulmonary structure and function, as well as the agents which dispose of the *Bacillus tuberculosis* and complicating or parasitic bacteria, may be in unfavorable variation, in arrest of evolution, or in reversion; and while such changes may allow invasion, they may result from disuse, tuberculosis, or other disease. In suitable environment variation would probably tend to evolve to the normal type and arrested evolution or even reversion might return to the original type.

1. Some of the Medical Aspects of Life Insurance.  
By SIR J. BARR.
2. A Second Report on Clinical Experiences with Spinal Analgesia: With a Second Series of One Hundred Cases.  
By A. E. BARKER.
3. Inherited Syphilis.  
By R. C. LUCAS.
4. The Medical Inspector of Schools as a Psychiatrist.  
By T. S. CLOUSTON.
5. The Critical Solution Point of Urine: A New Physico-chemical Method of Examination.  
By W. R. G. ATKINS.

**1. Life Insurance.**—Barr states that every insurance company should have at least three classes of risks—good, average, and moderate or impaired lives. 1. The candidate for insurance in the first class should live in healthy surroundings; he should be physically fit for his work, and his occupation should not be inimical to health. From the list should be excluded stock brokers and other gamblers, and physicians. He should be almost, if not entirely, a total abstainer from alcohol, and not a glutton; overeating kills almost as many as overdrinking. He should not be over six feet in height nor under five feet four inches. He should be in good health and free from all disease and processes of disease. Beware of the man who says he has never been ill a day in his life. Such diseases as measles, scarlet fever, etc., can be disregarded if they have left no sequelae. So also with coryza and common colds. But repeated attacks of influenza, or a history of such diseases as quinsy, pneumonia, pleurisy, bronchitis, rheumatism, gout, all forms of tuberculous diseases, diseases of the kidney, liver, and spleen, bad teeth and intestinal disorders, developmental defects, and hernia should at once exclude applicants from the first class. The applicant should have been vaccinated against smallpox at least twice. 2. The second class would contain the vast majority of the persons who insure at present. All persons should be excluded who have a strong family history of insanity and other diseases of the nervous system, consumption, cancer, rheumatism, gout, and syphilis. Every person with syphilis should pay a high premium. 3. The third class would include the derelicts, and yet with care it should be a large and profitable one. Carefully selected cases of heart disease are excellent risks, but great care must be taken to draw a distinction between lesions following rheumatic fever and those of a degenerative nature. Certain diseases of the kidneys also run a very chronic course. Frequent attacks of quinsy or rheumatism should be rated high, even though no heart disease has supervened, but glycosuria in a person over forty years of age need not be a complete bar to insurance. Myxodema being very amenable to treatment, may be accepted at a moderate rate, but exophthalmic goitre should pay a high premium. The following conditions should exclude from insurance except at prohibitive rates: Any acute illness with a high mortality until the danger is passed, all forms of active tuberculous mischief, malignant disease, diabetes in the young, Addison's disease, leucocytopenia, splenic anaemia, and lymphadenoma, insanity and all advanced diseases of the nervous system, advanced degenerative lesions of the heart and bloodvessels,

all diseases of the lungs where the vital capacity is reduced below two thirds of the normal, chronic alcoholism, etc.

**2. Spinal Analgesia.**—Barker, working with an injection compound much heavier than the cerebrospinal fluid, has obtained the following results: 1. The highest analgesias were obtained with the patient lying quietly on the side before and after injection. 2. The lowest analgesias were found after puncture in the sitting position, with subsequent change to the lying. 3. It was not found necessary to elevate into the Trendelenburg position with the head low at all, and it is unnecessary, if not positively dangerous. Further, this position becomes unnecessary for the convenience of operating, as the abdominal walls are so relaxed that manipulation within the peritoneum becomes easy. 4. The best results as to high analgesias and absence of after effects were found where the level of the body had not been altered after injection, and consequently the cerebrospinal fluid has been kept in a state of rest. The volume of the injected compound was about one c.c. The anæsthetic used was stovaine in a five per cent. solution of glucose in water. The specific gravity of the solution is 1.0230, as compared with 1.0070 of the cerebrospinal fluid. No adrenal derivative of any kind was used, and it is suggested that some of the ill effects reported may have been due to the adrenal principle employed and not to the anæsthetic drug at all.

By J. ADAMS.

**1. Inherited Syphilis.**—Lucas objects to the terms "congenital" and "hereditary" syphilis, and prefers "inherited," as implying only something derived from the parents, which is detachable and more correctly expresses the passing on of the spirochæta to the offspring. The cause of syphilis, whether inherited or acquired, is the presence in the blood of the spirochæta pallida, which can be demonstrated in the various secondary lesions, in the blood, and in the internal organs. It is a protozoan of spiral form from four to twenty micromillimetres long and one fourth micromillimetre in diameter, with a flagellum at each extremity. It stains a pale pink with Giemsa's fluid, while the coarser, highly refracting spirochæta refringens, with which it is often associated, stains dark purple. Inheritance of the disease from the father alone is entirely out of the question, and it follows that the infection of a mother by her syphilitic husband is essential. The inheritance is invariably through the syphilitic mother. This is supported by Colles's law that a syphilitic

infant cannot infect its mother's breast. When virulent the spirochæta penetrate the chorion or placenta and occasion miscarriages, macerated fetuses, or premature births; but when the virus is attenuated by time or treatment the placenta forms a complete protection to the developing fœtus, and it is the separation of the placenta at birth which allows the infection to take place through the umbilical vein. Hence the regularity of the secondary exanthematous stage from a fortnight to three months after birth. In these cases the separation of the placenta is the first stage and corresponds to the chance of acquired syphilis. Syphilis in a man is generally admitted to be capable of transmission to a succeeding generation for a much shorter time than syphilis in a woman, which supports the view that for transmission it is necessary that the woman be first infected. It is probable that the disease can be transmitted by milk, but not necessarily so. It is obvious, as the greater cannot be included in the less, that a spirochæta cannot be carried in a spermatozoon; but this does not exclude the possibility of the spirochæta being conveyed by the fluid parts of the semen. Indeed, it seems almost necessary for the latter to be so to account for the cases of inherited syphilis conveyed after the healing of the chancre. A question open to discussion is whether syphilis inherited is capable of transmission to the third generation. The author saw one instance in which the child of parents, both of whom suffered from inherited syphilis, was free from the disease. Syphilitic parentage is probably responsible for a greater infant mortality than any other single disease or condition. This mortality is greatest in those families where both parents have suffered from chancre syphilis and obvious secondaries. The trite definition that syphilis is "a fever diluted by time" is applicable to the inherited as well as to the acquired disease. The secondary stage of inherited syphilis is characterized by eruptions varying from slight brown macular syphilides to pompholyx, by snuffles, stomatitis, condyloma, wrinkled skin, and wasting, and enlargement of the spleen and liver. Then follow changes in the bones—epiphysitis, Parrot's nodes, craniotabes, and bent bones. It cannot be too strongly insisted on that the moist eruptions and ulcerations about the mouth and anus, as well as the vesicular skin affections, are charged with the spirochæta and are highly contagious. From the second to the sixth year there is commonly a rest in the symptoms, which is quite characteristic. But now the characteristic physiognomy has been gradually formed—the flattened nose, the square forehead, the stunted figure, and the pallid face. During the second dentition are to be noted the three signs pointed out by Hutchinson—the notched incisor teeth, interstitial corneitis, and syphilitic deafness. A characteristic change occurs in the first molars, as first described by Moon. They are reduced in size and dome shaped through the dwarfing of the central tubercle of each cusp. The eyes may be early affected by a choroidoretinitis, and the ears are also affected. Some of the characteristic lesions to be sought for in the illness. Enlarged spleen and liver associated with rickets are almost invariably of syphilitic origin. When the inherited disease attacks both the eyes and the ears, at menarche and at marriage, the patient is almost certain to die of syphilis.

known as infantilism is produced at a period when the sexual characteristics should be pronounced. A certain proportion, but not a large one, of epileptics, deaf mutes, and idiots show signs of inherited syphilis. Great care should be taken in diagnosis, in future the most certain test of the disease being syphilis will be the presence of spirochæta pallida in the part affected. This organism has an extraordinary persistency, producing local symptoms after lengthened periods. But mercury controls its development. Metchnikoff has shown that some hours after direct inoculation the application of a calomel ointment to the sore is sufficient to kill the organism and prevent the occurrence of secondary symptoms.

**4. Cytodiagnosis.**—Sawyer discusses the cytodiagnosis of pleural serous effusions, cerebrospinal fluids, and ascitic fluids. Speaking generally, the cells found in all effusions and the percentage of each kind of cell to the total number vary in the same way in all these pathological fluids, according to the disease which produces the effusion. In making a cytological examination it is necessary to obtain the fluid as soon as possible after it has been removed from the body, as after a few hours the cells begin to degenerate. Care should be taken not to centrifugalize too long or too forcibly. The cells to be considered from a cytological point of view are (1) the small lymphocytes; (2) the polymorphonuclear cells; and (3) the endothelial cells. Very few cells may be present in serous effusions or cerebrospinal fluids, especially the latter. As the result of his observations the writer reaches the following conclusions: 1. Effusions of tuberculous origin contain a large percentage of small lymphocytes, ranging from 50 to 100 per cent. 2. Effusions of acute inflammation contain a large percentage of polymorphonuclear cells, ranging from 64 to 97 per cent. 3. Mechanical effusions contain chiefly endothelial cells, the highest count being 98.8 per cent. 4. Effusions due to malignant disease can rarely be diagnosed by cytological methods alone, but when such a condition is suspected to be present the predominance of endothelial cells would greatly support that view.

1. Urgency Treatment of Wounds of Joints.  
By P. HARDOUIN.
  2. Study of the Gastric Secretion without Use of the Stomach Tube,  
By LÉON MUENIER.
  3. Anaphylaxis,  
By R. ROMME.
- 1. Urgency Treatment of Wounds of Joints.**—Hardouin says that the knee and the instep are the two joints which most frequently demand emergency treatment at the hands of the surgeon, and in this article he deals chiefly with surgical intervention in these joints. Early and thorough intervention is urged, and in conclusion he says that a surgeon in the presence of a wound of a joint should remember that if he is to attain success he must intervene quickly and freely, and that in the cases in which one becomes hesitant on account of the necessity of a rather extensive intervention he should hold to the idea that abstinence and hesitation continue to be the worst disasters in this class of cases.
- 2. Study of the Gastric Secretion without Use of the Stomach Tube.**—Muenier utilizes the

following method for the determination of the length of time required for dissolution in the gastric juice. A capsule of thin rubber tissue, with its aperture closed by means of catgut and containing a drop of ether, is swallowed by the patient during gastric digestion. The catgut is thus submitted to the action of the gastric juice, and after a certain length of time it gives way and allows the ether to escape and come into contact with the contents of the stomach, with the result that the patient indicates the precise moment of dissolution of the catgut by a very characteristic eructation of ether. He describes two series of experiments, and believes that this method possesses certain advantages over the usual method of washing out the stomach.

1. Protection of the Child. Puericulture in Lille, By V. BUE.
2. The Inclusion of Parafin at Seventy-eight in the Nasal Prothesis, By LEROUX.
3. Latent Nephritis in the Child, By R. ROMME.

**2. The Inclusion of Parafin at Seventy-eight in the Nasal Prothesis.**—Leroux alleges that there are great advantages of his operation over the usual method of injection of parafin into the subcutaneous tissues. The essential point of his operation is the subcutaneous preparation of a pocket into which the parafin is introduced and spread so as to produce the effect desired. He asserts that the æsthetic results are better than those obtained from injection, while the technique is simplified and all danger is removed.

11. Reply to the Above, By VON FRANQUÉ.
12. History and Indications for Oxygen Treatment, By GALLI.
13. Report for the First Year of the Institution for the Care of Children in Weissenburg (Concluded), By DÖRFLER.
14. Obituary of Moritz Schmidt, By SENATOR.

**2. Cutaneous Tuberculosis in Children.**—Hamburger says that the papulosquamous tuberculides are met with quite frequently in childhood, and that they are of great clinical interest from a diagnostic point of view at this age.

**3. Neurology of the Tongue.**—Flesch has studied by means of experiments the conditions present with 1, isolated paralysis of one genioglossus; 2, of one styloglossus; 3, paralysis of both genioglossi; 4, paralysis of the left genioglossus and lingualis; 5, paralysis of the left genioglossus and styloglossus; 6, isolated paralysis of the left hyoglossus; and, 7, paralysis of the internal muscles. Observations were made concerning the position and form of the tongue when at rest, the direction of the raphe, lateral and vertical motility, touching the molar teeth with the tip of the tongue, putting out the tongue, lateral motility of the tongue when put out, retraction of the tongue, empty swallowing, fibrillary twitchings, articulation, and sensibility. He divides the forms of paralysis met with into three groups, glossoplegia totalis, in which all of the muscles, both internal and external, are involved; glossoplegia externa; and glossoplegia interna. The following combinations were observed from foci in the cortex: 1, Glossoplegia bilateralis totalis; 2, facial paresis or motor aphasia combined with a monolateral external paresis of the tongue; 3, complete motor aphasia without paresis of the tongue. Hemiatrophy with tremor, without the reaction of degeneration, has been observed as the result of a lesion in the semi-oval centre near the internal capsule. He finds with regard to the peripheral paralyses of the hyoglossus that these should be divided into three groups: 1. If the lesion is situated between the base of the brain and the anterior condyloid foramen there will be a monolateral atrophic paralysis, glossoplegia totalis unilateralis atrophica, with reaction of degeneration, pain as a result of the lesion and motor involvement of the lower branches of the hypoglossus; 2, if the nerve is affected extracranially, as for example in the pharynx where the hypoglossus branch is given off there will be a monolateral atrophic weak glossoplegia, with involvement of the lower branches of the hypoglossus; 3, if the nerve is affected intracranially, as for example in the same side of the brain stem, there will be a monolateral atrophic weak glossoplegia, with reaction of degeneration, pain as a result of the lesion and motor involvement of the lower branches of the hypoglossus; 4, if the lesion is situated between the base of the brain and the anterior condyloid foramen there will be a monolateral atrophic paralysis, glossoplegia totalis unilateralis atrophica, with reaction of degeneration, pain as a result of the lesion and motor involvement of the lower branches of the hypoglossus; 5, if the lesion is situated between the base of the brain and the anterior condyloid foramen there will be a monolateral atrophic paralysis, glossoplegia totalis unilateralis atrophica, with reaction of degeneration, pain as a result of the lesion and motor involvement of the lower branches of the hypoglossus; 6, if the lesion is situated between the base of the brain and the anterior condyloid foramen there will be a monolateral atrophic paralysis, glossoplegia totalis unilateralis atrophica, with reaction of degeneration, pain as a result of the lesion and motor involvement of the lower branches of the hypoglossus; 7, if the lesion is situated between the base of the brain and the anterior condyloid foramen there will be a monolateral atrophic paralysis, glossoplegia totalis unilateralis atrophica, with reaction of degeneration, pain as a result of the lesion and motor involvement of the lower branches of the hypoglossus.

tation of movement in all. The author gives a brief account of a number of cases of nervous affections of the tongue which have come under his observation.

4. **Lumbar Anæsthesia.**—Holzbach describes the method of administration of the mixture of stovaine used for the lumbar anæsthesia in eighty cases of major operations on women. While the patient is sitting in her bed a puncture is made in the median line between the second and third lumbar vertebrae, the trocar removed from the needle, two or three c.c. of the cerebrospinal fluid allowed to escape, and the mixture of stovaine then injected very slowly through the tube, the injection lasting from three to four minutes. The needle is then removed with a jerk, which causes the patient to sit upright sharply and thus prevent any escape of the fluid through the puncture. Brusque changes of position are to be avoided, as they cause changes in the level of the fluid and may cause the extension of the poison to regions where the vital centres will be endangered.

5. **Treatment by Means of Bier's Hyperæmia.**—Gebele reviews the experiences in the surgical clinic at Munich with this form of treatment of tuberculosis of the bones and joints.

7. **Subcutaneous Injection of Pyocyanasis.**—Bermbach says that a well marked local and general reaction follows the injection of pyocyanasis. The local symptoms are redness, swelling, and pain, the general fever, with increase of temperature and acceleration of the pulse, headache, dizziness, nausea, and vomiting. The cause of the reaction is the toxin contained. Treatment should be begun with very small doses, which are to be gradually increased.

8. The Limitation of Laparotomy by Vaginal Methods of Operation, By LEHMANN.
9. Concerning the Results as Yet Produced in the Consulting Places of Munich with Propositions for the Further Extension of These Arrangements, By OPPENHEIMER.
10. Concerning Ophthalmoreaction, By WIENS and GÜNTHER.
11. Treatment by Means of Bier's Hyperæmia (Concluded), By GEBELE.
12. Obituary of Professor Wilhelm Nieberding, By KUPFELSSNER.

1. **Parabiosis.**—Sauerbruch and Heyde give the name parabiosis to the new condition produced in animals which are experimented upon when they are organically connected together in an artificial manner, and present their observations in regard to the anatomy and the physiology of this condition.

2. **Meat Poisoning and Widal's Reaction.**—Liefmann observed fifty soldiers taken sick in barracks within a few days of each other with symptoms of ptomaine poisoning, ascribable to their food, and with the *Bacillus enteridis* Gärtner present.

Widal's reaction was positive in all, though no typhoid bacilli could be found.

5. **The Cutaneous Reaction to Tuberculin.**—Göbel thinks that in children between the ages of one and twelve the positive reaction to von Pirquet's cutaneous test is almost demonstrative of the presence of tuberculosis, but with adults a conclusion from the positive reaction must be drawn with care. A negative result in adults after repeated inoculations makes it extremely probable that that person is free from tuberculosis.

6. **Injury of the Duodenum by Contusion.**—Steintal reports a case of this nature. A man, eighteen years old, was run over by a wagon and brought to the hospital. Laparotomy was performed and lacerations found in the duodenum and elsewhere in the intestine which necessitated suturing and a gastroenterostomy. The patient recovered.

7. **Symptomatology of Exudative Pleuritis.**—Von Schroetter describes a number of cases which illustrate the changes observable by bronchoscopy in this disease.

8. **Limitation of Laparotomy by Vaginal Methods of Operation.**—Lehmann points out how since 1894 there has been a growing tendency for the vaginal methods of operation to take the place of laparotomy in all kinds of gynecological operations, and closes with an advocacy of the vaginal Cæsarean section.

11. **Bier's Hyperæmia.**—Gebele finds this treatment to be not a universal cure, but to be of good service in acute, fresh cases of inflammation, better than in cases of tuberculosis.

9. Ocular Symptoms and Diseases Accompanying Adenoids, By C. H. MAY.
10. Adenectomy during Acute Middle Ear Disease, By P. D. KERRISON.

3. **Myxœdema, with Report of a Case.**—Davis refers the term to Ord, who proposed it for "an essential condition in the cretinoid affection occasionally observed in middle aged women." It is synonymous with the *cachexia pachydermique* of Charcot, and the *cachexia strumipriva* of Kocher. Whether it follows removal of the thyroid, as alleged by some writers, there is certainly a marked atrophy of the thyroid in myxœdema, and the disease at least appears to be dependent upon loss of function of the thyroid gland. It occurs most frequently in married women between forty and forty-five. It may follow the exanthemata, rheumatism, erysipelas, malaria, and tuberculosis. One variety results from the destruction of gland tissue by disease, while the congenital or infantile form is also

known as cretinism. Another variety is that which follows the removal of the thyroid gland. If properly treated it is susceptible of great improvement. If untreated it lasts from six to twenty years. It is apt to be confounded with exophthalmic goitre and chronic nephritis. Suitable climate, baths, and good hygienic treatment in general are indicated; also arsenic, strychnine, ergot, pilocarpin, and thyroid extract.

**4. Subcutaneous Emphysema following Exploratory Puncture of the Chest.**—Gittings states that this sequel of pleural puncture has rarely been reported. Three cases are narrated. The lung is also punctured, a localized pneumothorax resulting, and this develops subcutaneous emphysema along the line of puncture. Another possible explanation is that it is due to infection from an air producing bacillus. There may be no ill effects from the emphysema, while a resulting pneumothorax causes discomfort, if not actual danger. In puncturing the chest one must not forget the possible proximity of firm and unyielding lung tissue to the chest wall, and the author thinks the operation is too often undertaken with disregard of the element of danger, especially in children. When a small collection of fluid overlays a more or less consolidated lung diagnosis by percussion and auscultation is often unsatisfactory, and puncture becomes imperative, but the lung must be avoided unless one is searching for an intrapulmonary collection of fluid.

**10. Adenectomy during Acute Middle Ear Disease.**—Kerrison thinks one should always ask whether the removal of the tonsils and adenoids is a necessity, and whether the pharyngeal growth will retard or check tympanic resolution. He offers the following facts: 1. The two operations should be performed at one sitting, under general anesthesia. 2. Adenectomy involves risk to the healthy ear. The acute inflammation is favorable for the throat operation, and if the drum membrane is incised further damage to the ear may be saved. 3. Free bleeding accompanying the removal of the adenoids favors tympanic resolution. 4. In many cases of acute otitis media recovery is not only tedious and slow, but will be incomplete until the adenoids are removed. The drum membrane remains retracted and congested, and slight provocation will induce recurrence of the middle ear trouble.

2. Some Experiences with X Ray and High Frequency Treatment. By F. GARDNER.
3. Rheumatoid Arthritis. Its Etiology, Clinical Symptoms, and Pathology. By KATHERINE S. CLARK.

**3. Rheumatoid Arthritis.**—Clark has observed a considerable number of cases of rheumatoid arthritis in different stages of the disease. She thinks that the opinion that rheumatoid arthritis owes its origin to some lesion of the nerves cannot be held. The bacterial theory is also improbable, because no specific organism, present in all cases, has been discovered. But she is of the opinion that it is of organismal origin, the organisms having their seat in some organ, where they evolve toxins, which are thrown

into the blood stream. She has found definite changes in the spleen, liver, kidney, pancreas, skin, ovary, stomach, and bladder. In the spleen the most prominent histological change was found in thickening of the walls of the central artery of the Malpighian body, this thickening being of the nature of a hyaline degeneration. The capsule and trabeculae were also more or less thickened with dilatation of the sinuses of the pulp and some thickening of walls. In the liver there was increased connective tissue in the portal tract, with thickening of the walls of ducts and vessels. The principal changes in the kidney were apparently primarily arterial, and the new tissue had undergone hyaline degeneration. In some part the glomerulus was markedly hyaline. Bowman's capsule frequently showed fibrous thickening, and throughout the organs, particularly along the vessels, were localized patches of fibrous connective tissue. In the pancreas the pathological changes were even more marked, increase of connective tissue throughout the organ being very extensive. There was degeneration of the parenchyma, and hyaline thickening of the vessels and ducts, with a proliferation of their lining epithelium. In the skin sections there were present atrophy of epithelium, glands, and hair follicles, increase of fibrous tissue in the cutis vera, with hyaline degeneration in the deeper layers. The ovary showed little abnormality, except in the greatly thickened vessels, the coats of which were markedly hyaline. In one case, the almost total absence of germinal epithelium and follicles was noticeable, also extensive fibrosis, and thickening of the hyaline vessels. The hollow organs, stomach and bladder, were to the naked eye markedly thickened, this change being principally in the muscular coat. Amongst these pathological changes, perhaps the most remarkable are those described in connection with the skin, changes which are evidently widespread. It is difficult to account for these otherwise than on the ground of an apparently specific neuropathic origin, and probably, in addition, they may partly result directly from the arterial changes. These arterial changes, being so widespread throughout the body, can only be explained by the circulation of some chronic irritant in the blood stream, which, in its course, involves joints as well as organs. The author is therefore of the opinion that the joint changes are merely symptomatic and that they are only part of a general chronic toxæmia.

#### Proceedings of Societies.

##### NEW YORK ACADEMY OF MEDICINE.

Meeting of January 13, 1908.

The President, Dr. JOHN A. WYETH, in the Chair.

Following the reading of the annual reports was a "symposium" on tuberculosis in infants and children, under the auspices of the Section in Paediatrics.

**The Pathological Findings.**—Dr. JOHN McCREA, of Montreal, read this paper. He said that when one dealt with the pathology of tuberculosis in children one met with many conflicting statements

and ventured at once on controversial ground. Much interest centred about the primary tuberculosis of young children. Some English pathologists gave a considerable frequency for this, and he thought that every one in this country would concur in the reasonableness of Dr. Bovaird's twice in 125 cases and Dr. Holt and Dr. Northrup's 1.3 per cent. It was probably the case that the average human being could overcome an infection by bovine bacilli more easily than that by human bacilli. The statement that bovine tuberculosis was less virulent than human tuberculosis for human beings rested upon the fact that the cases so observed had generally been of the lymphoid form or from cases of slow progression. To the contrary must be stated the observation that apes were more virulently attacked by bovine than by human tuberculosis. There was a slow type of infection in children which they called "bovine," viz., a slowly progressive tuberculosis, tending to overgrowth and dry caseation, affecting mainly the lymph nodes. Children were liable to infection by air borne bacilli of the human, less frequently of the bovine type, and were liable to infection by ingestion of bovine bacilli from milk and other forms of food of which milk was a component part. European figures, collected in Lubarsch and Ostertag, showed that, of 396 examinations of milk, 9 per cent. contained bacilli; and of 244 butter examinations, bacilli were found in 8.3 per cent. This was probably a greater percentage than existed in the United States or Canada. The exact cultural studies made in Germany, the United States, and England upon the bacilli isolated from cases of tuberculosis showed that, of children under five years of age affected by tuberculosis, four fifths were probably infected by air borne human bacilli. One fifth might show the "bovine" form, and this percentage decreased as the age progressed. We must admit that in all probability the bacilli could pass through tissues and glands without leaving visible traces, and could remain in tissues for a considerable time without exciting even so slight a lesion as to be recognizable only by the microscope. When infection occurred in children, the first site in air borne infections was in some part of the lymphoid tissues of the upper air passages or the lungs, and in intestinal infections the mesenteric nodes. He asked if it was possible to fix positively the primary seat of infection as intestinal. If the mesenteric nodes showed caseous or calcareo-caseous changes more marked than the thoracic, or if there was ulceration of the bowel or tubercles of the mucosa without cavitation, all these in artificially fed children suggested intestinal infection. Advanced thoracic lesions should be allowed to weigh in favor of infection by the respiratory channels. One must also admit that tubercle bacilli from milk might stick to the fauces and gain a foothold on the thoracic lymphatics, but, on the other hand, inspired bacilli might go down with food or with saliva, so in that regard honors were almost even. His personal experience with foundlings, artificially fed on milk that was pasteurized, showed that they were practically free from tuberculosis. In 747 autopsies, in which sixty per cent. of the subjects were three months of age or under, tuberculosis was found but five times (0.66 per cent.). He knew that these children were of low vitality, that pasteurized milk

might well contain bacilli, attenuated but not dead, that the Province of Quebec had a fair amount of bovine tuberculosis, and that three months of life was sufficient time to allow an infection to take good hold. There must surely be less intestinal tuberculosis of infants than had sometimes been urged. He thought the truth was that we had laid too great stress upon milk borne tuberculosis where the bovine disease was prevalent, and had forgotten that children were more liable to the human form than adults, in that, if they did become exposed to a house or other local infection, they spent less time away from their dangerous surroundings than their adult relatives. As to the other forms of tuberculosis, why in certain cases did the disease manifest itself in bone and joint and remain there? This phenomenon was some expression of the sum total of lower bacterial virulence and heightened resistance of the individual tissue. With regard to meningeal tuberculosis, he wished to show that in a large percentage of the cases it was merely a local evidence of a generalized tuberculosis. It occurred either as secondary to a bronchial or other gland infection, without there being disease elsewhere, or as a local manifestation of the disease that existed in many other organs. The latter was the more frequent.

**Recent Diagnostic Methods.**—Dr. WILLIAM H. PARK read this paper, and, before touching upon the technique, spoke on the meaning of the reaction following inoculation of skin and eye, as recently proposed. If one took an animal and injected into it a minute quantity of serum, after ten days that animal would be sensitized, so that if a fairly large quantity of serum was injected the animal would die in convulsions, whereas if the same dose of the serum was given to another animal not so sensitized the results would be absolutely harmless. White of egg would sensitize an animal; it was also found that other proteids, as well as bacterial proteids, would in the same way sensitize animals. Thus, if a guinea pig, rabbits, or even men, were injected with dead tubercle bacilli, they would, after ten days, be sensitized. This sensitizing would last for a considerable period of time, until the newly formed substances were eliminated from the body. The important point was that a minute quantity of suitable proteid would thoroughly sensitize an animal or man to similar proteids, and this sensitization would last for months or years. When one got a reaction from the subcutaneous injection of tuberculin, it was not a reaction because of the presence of tubercle poison in the body, but because of the formation of antibodies due to the body having reacted to the tuberculous infection. Therefore, if a body ceased to produce these protective substances, the poison in the tissues adjacent to the disease and in the circulation would not be neutralized, and no tuberculous reaction would occur. These reactions were not reactions to bacterial poison, but to the body products in response to the poison. In advanced cases, therefore, reactions would frequently not occur. After referring to the old method of injecting Koch's original tuberculin, he called attention to the new methods. Von Pirquet placed tuberculin upon the abraded skin, using a 1 to 4 strength, one drop of which was rubbed into the abraded skin. He found that in tuberculous cases he got a

typical reaction. He usually took an arm, and made a little vaccination mark; that would be the control spot. Then two other "vaccinations," or scarifications, were made, and into them was rubbed a 25 per cent. solution of Koch's tuberculin. In the course of eight, twelve, or twenty-four hours appeared a papular swelling and redness, of the size of a dime or larger. So by contrasting the reaction of the two scarifications with tuberculin with that without the tuberculin, one could judge of the difference between a very slight inflammatory reaction due to the abrasion and that due to tuberculin. Wolff-Eissner believed that he might get the same reaction without the use of this scarification by applying it to the conjunctiva, and he tried using a 1 to 10 dilution, placing one drop of it on the lower eyelid. This gave a marked reaction. Calmette, in order to avoid such a marked reaction or any non-specific irritation, tried a method of purifying the tuberculin by precipitating the toxins in 65 per cent. alcohol. This precipitate was washed and dried, and a 1 per cent. solution of it was made in water. This 1 per cent. solution was then used as in the Wolff-Eissner method. The reaction might develop in from six to thirty-six hours. It was very important in following up these new methods to carefully note the amount of reaction that occurred, and the following scheme had been adopted by many for the sake of uniformity: Two solutions were employed in diagnosis, which contained 0.5 per cent. (No. 1) and 1 per cent. (No. 2) respectively, and which might be used successively in each eye if time permitted. In this way unnecessarily severe reactions might be avoided. The eyelid should be held down until the drop was distributed about the sac without overflowing on the cheek. The same eye should not be used for a second test, as it appeared to become sensitized to some degree by one test. The tested eye should be kept from external irritation by rubbing, wind, dust, and smoke. The first symptoms of a reaction appeared in from three to twelve hours in some cases, but might be delayed twenty-four or even forty-eight hours, and continued for a week. The presence of a reaction was indicated by a scratchy feeling or secretion and redness of the inner canthus, caruncle, on lower lid, which might increase and include the entire conjunctiva with edema of the lids. The following schema was proposed for recording reactions: *Negative*: No difference in color when the lower eyelids were pulled down. *Doubtful*: Slight difference with redness of the caruncle.

± = Distinct palpebral redness with secretion.

• = Ocular and palpebral redness with secretion, well marked.

+++ = Deep injection of entire conjunctiva with edema of the lids and photophobia, and secretion. *Contraindications*: Any existing disease of the eye or lids, conjunctivitis, blepharitis, trachoma, keratitis, and iritis. Eye strain from errors of refraction need not prevent the use of the test so far as had been observed. The objections to the test were slight. No permanent ill effects had remained. Dr. Paul said it was set too early to estimate the exact value of either the skin or the eye reaction. Most observers believed that the skin reaction was little less apt to occur than the eye reaction. In young

children the reaction was believed to indicate generally an active focus of tuberculosis, while in older children the reaction became less definite, as it might mean either a present or recently healed infection. In the adult the reaction was present in such a large percentage of the cases that it was hard to know whether there was an active or a late tuberculosis, or whether the bacilli had simply been absorbed through the mucous membrane, giving no reaction whatever except sensitizing the individual. Negative results were always helpful in excluding absorbed tubercle bacilli, latent or active tuberculosis.

**Laboratory Aids to the Diagnosis of Tuberculosis.**—Dr. T. HOMER COFFIN considered this subject in its relation to the examination of the blood, urine, sputum, feces, bodily fluids, discharges, etc. Microscopical examination of the blood in various forms of tuberculosis of children usually showed a marked diminution in the hemoglobin and the number of red cells. There might be a leucocytosis if the process was associated with suppuration, though there were some cases of tuberculous suppuration which showed none. A blood count might in some cases be of value in distinguishing tuberculous from other forms of meningitis. Chronic cystitis or a tuberculous pyelitis might be a local manifestation of a general tuberculous process. The bloody or bloody purulent sediment of the acid urine in urogenital tuberculosis contained shredlike or rounded, sometimes ragged, flocculi, pin head in size, which upon microscopical examination showed pus cells and fatty detritus. If smears were made and stained, tubercle bacilli were found as dense collections among these cells. In examining urine for tubercle bacilli one should guard against mistakes with the smegma bacillus. The method of Findley was advocated to overcome the difficulty of obtaining sputum in infants and young children. Holt, in sixty-seven cases of pulmonary tuberculosis in children under two years of age, had made the diagnosis by an examination of the sputum in eighty per cent. of the cases when, according to the physical signs, the disease was not far advanced. A large number of uninuclears was present in tuberculous exudates; the process was usually insidious in development and was accompanied by slight inflammation. In tuberculosis of the cerebrospinal canal and the pleural, pericardial, and abdominal cavities the uninuclear cells did not always predominate in the fluid, for cases known to be tuberculous had shown the polymorphonuclears most numerous at an early stage of the process, but later the uninuclears predominated. Therefore the predominating type of cell was more indicative of the stage and severity of the disease than of its etiology. The cerebrospinal fluid in tuberculous meningitis was usually clear, and upon examination of the sediment the uninuclears were present in numbers. In epidemic and sporadic cases of meningitis the fluid was usually cloudy, and the specific bacteria were found among or in the multinuclear cells. Some writers expressed their opinions regarding the value of the examination of the feces in patients with tuberculous lesions. This examination might be of great value in children with pulmonary tuberculosis, for the bacilli are sometimes excreted in the feces. In the examination of the

the bacilli were often found in the stools after careful search. Tuberculous affections of the eye, ear, nose, throat, urethra, or vagina in children might often be distinguished from lesions due to other microorganisms by a microscopical examination of the secretions. Tuberculous glands were diagnosed by examination of sections of hardened tissues from portions of the excised glands.

**Channels of Communication; Their Relative Significance.**—Dr. S. McC. HAMIL, of Philadelphia, read this paper. He said the question of the modes of introduction of the tubercle bacillus into the human body remained at present entirely unsettled, more unsettled in fact than a few years ago, when we accepted it as proved on the basis of post mortem evidence that infection by inhalation was the chief if not the only channel. The avenues by which the tubercle bacillus got into the human body were the maternal circulation, the skin, the ear, the conjunctiva, the urogenital tract, and the respiratory and intestinal tracts. All but the last two of these were accepted as proved, but considered of such infrequent occurrence that they need have no place in the present discussion. In the vast majority of tuberculous subjects infection occurred either through the respiratory or the alimentary tract. The experimental results bearing on inhalation tuberculosis which were the most deserving of consideration in detail were those of Flügge. He produced tuberculosis of the lungs by inhalation in guinea pigs, rabbits, goats, calves, and dogs by means of a very small number of tubercle bacilli which were floated in the air in the shape of droplets. From these experiments he concluded: 1. That inhalation represented a mode of infection as efficacious as subcutaneous injection, with regard to the very small dose required, and that inhalation infection produced a disease more rapid in course than did subcutaneous injection. 2. That it might be accepted as proved by the inoculation of the peripheral parts of the lung into guinea pigs immediately after exposure to an atmosphere containing droplets that at least some of the bacilli inhaled with the air in the shape of droplets were carried to the finest bronchi. 3. That the quantity of bacilli required to produce manifest symptoms of disease, when ingested with the food, was millions of times larger than when infection was by inhalation, and a fatal termination took place at a much later period. He accepted it as proved, therefore, that inhaled tubercle bacilli were capable of producing tuberculosis directly, and not because some of them were swallowed and penetrated into the body from the intestine or throat. The contention of Flügge that the floating of bacilli infected droplets in the air was more dangerous than the bacilli laden dust was not in accordance with the results of other investigators and was directly opposed to clinical experience. The work of Bartel and Spicler seemed to indicate that the intestinal tract was the most common avenue of infection. Infection through the medium of the intestinal tract has obtained a great deal of support in recent years. The following conclusions were offered: 1. That it was impossible to gain any knowledge as to the port of entry either from the location or the degree of development of the tuberculous lesions. 2. That fetal infection was proved, but not common. 3. That infection through the mouth, tonsils, and pharynx was

of frequent occurrence and might be produced by inhalation or ingestion. 4. That primary inhalation infection through the lungs did occur. 5. That infection through the intestinal tract was definitely proved. 6. That the bronchial glands and lungs might be infected through the latter channel as well as through the lungs. 7. That the relative significance of the various modes of infection was very difficult to determine on the basis of our present knowledge, since it had been clearly shown that it mattered not from what point the tubercle bacillus was introduced—it could eventually reach the bronchial glands and lungs without leaving any evidence of its means of entrance. It was probable, however, on account of the greater exposure of those portions of the body, that infection through the upper respiratory and alimentary tracts was the most common, and next to this, for similar reasons, through the lower respiratory and intestinal tracts. As to which of the two latter constituted the more frequent channel, it would seem that the nature of the exposure should prove a determining factor. If infection occurred when the bacillus was carried in with the food or to the lips and mouth in kissing, or by infected hands, nipples, toys, drinking cups, or the various feeding utensils, it must almost certainly be by the alimentary tract. If, on the other hand, the bacilli laden dust or droplets were inspired, they were caught up in large part on the mucous membrane of the upper air passages, whence they might be swallowed, or they were carried on to the lungs. Certainly, in infants and children, exposure to the former group of conditions was much greater than it was in adults, and, since we must admit that the greater portion of inhaled bacilli found lodgment in the upper air passages, from which point they might be swallowed, and since infection by the intestinal tract had been absolutely determined in children as well as experimentally in animals, we could safely conclude that intestinal infection in early life was more common than in later years, and, with the additional support of much experimental work and much investigation, he was prepared to believe that infection by the intestinal tract was more common in infants and children than infection through the lungs.

**The Management and Treatment of Tuberculosis in Infants and Children.**—Dr. JOHN LOVETT MORSE, of Boston, read this paper. (See page 350.)

Dr. DAVID BOVAIRD, Jr., said it was a question of great importance to the public, and upon which a great deal depended in the fight against tuberculosis, to know the mode of infection and the relation between bovine and human tuberculosis. He called attention to the contention of the two prominent schools, each opposing the other.

Dr. HENRY DWIGHT CHAPIN said that those who had to deal with disease of childhood recognized the great difficulties encountered in the diagnosis of tuberculosis in its early stages. All clinicians looked upon laboratory aids with the greatest hopefulness. The surgical treatment of tuberculous peritonitis was filled with hope, but the trouble was in getting an early diagnosis of the condition. He believed that the danger from milk borne tuberculosis was overestimated, and it was a fact that, while tuberculosis in cattle was on the increase, tuberculosis in man was on the decrease. If bovine tuberculosis was of such

importance as a causative factor of tuberculosis in man, this would not be true.

Dr. HARLOW BROOKS said that, so far as the anatomical lesions went in judging of the point of infection, intestinal infection was rare, whereas respiratory tuberculosis was common. These anatomical lesions, however, were not infallible in locating the seat of infection. He had had considerable experience with infections occurring in animals, and at one time there had been an outbreak of tuberculosis in the orangoutang and chimpanzee, and he had stamped it out by attention to the prevention of its dissemination by respiration, the intestinal factor in these cases being negative. It was wiped out simply by preventing the possibility of infection by the respiratory tract.

Dr. WILLIAM P. NORTHRUP condemned the overheating of the apartments and houses, especially in New York; this caused much of the acute and catarrhal conditions in children and adults. One of the best ways to check tuberculosis was by cooling the houses. It was unfortunate that the trachea and oesophagus were situated so close together, for children were so apt to inhale what was regurgitated and swallow what was brought up through the trachea. He was surprised at Dr. McCrae's statement that tuberculoma in the brain was one fourth as frequent as meningeal involvement. His experience was that very little tuberculosis occurred in the brain itself. The Calmette reaction was a great aid, and presented a remarkable phenomenon.

Dr. ROLAND G. FREEMAN believed that, no matter what opinions had been held in the past regarding the channels of inoculation, such opinions must be modified by the results of the latest researches. There were many cases seen at autopsy which were apparently cases of inspiration tuberculosis, but which were, in fact, cases of intestinal origin, with little trace of the site of inoculation in the intestine left. Milk from tuberculous cows often contained no tubercle bacilli, or, if it did, they were so diluted that they might not gain an entrance into the system.

Dr. A. F. HESS said that at present one of the greatest points of variance in different countries and among various capable observers was in regard to the relative practical importance of bovine and human tuberculosis, especially as concerned infants and children. The importance of the question from a prophylactic point of view was not open to doubt. Attempts to solve this matter by means of ascertaining the frequency of tuberculosis in cattle or by entering into the previous history of the child and considering the question of exposure to bovine or human tuberculosis were indecisive. It seemed to him that the only way we could obtain an answer to this question was by the slow and tedious method of distinguishing the types of bacilli. It was well established that by means of morphology and cultural and biological tests the human and bovine types might be distinguished. This had been done here, but to a much greater extent by the British County and the German Imperial Health Departments. It was only by hundreds of such investigations of serial cases that we could come to any conclusions.

Dr. A. JACOBI dissented from what Dr. Meigs had said regarding the giving of opium to children.

It was not a rank poison, and might be of great value when they were subjects of tuberculosis. He believed the tubercle bacillus could get into the system through an intact mucous membrane, and he cited a case in proof of this statement. Pasteurizing milk was so carelessly done that Dr. Jacobi advocated the bringing of the milk to the boiling point; one then would be sure to obtain the proper temperature.

### Book Notices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

*Modern Medicine: Its Theory and Practice.* In Original Contributions by American and Foreign Authors. Edited by WILLIAM OSLER, M. D., Regius Professor of Medicine in Oxford University, England, etc.; Assisted by THOMAS McCRAE, M. D., Associate Professor of Medicine and Clinical Therapeutics in the Johns Hopkins University, Baltimore. Volume III. Infectious Diseases (Continued). Diseases of the Respiratory Tract. Illustrated. Philadelphia and New York: Lea Brothers & Co., 1907. Pp. ix-17 to 960.

Rather more than half of this volume is required to finish the consideration of infectious diseases; then the aetiological basis of classification is supplanted by the anatomical, and pneumonia, for example, though undoubtedly originating in infection, is more conveniently and therefore more properly dealt with as a disease of the respiratory tract. One might have expected the same course to be pursued with tuberculous disease, so overwhelmingly important are its pulmonary manifestations, but elsewhere than in the lungs it assumes a seriousness that is not to be underrated. We cannot yet classify diseases satisfactorily on any one plan, and it is doubtful whether a great deal could be gained if we could do so. Much *Gehirnschmerz* has been spilled over the unprofitable subject of classification.

Of the diseases classed as infectious, those treated of in this volume are: Malta fever (by Colonel David Bruce, of the British army), beriberi (by Dr. Maximilian Herzog, of Chicago), anthrax, rabies, and glanders (by Dr. M. P. Ravenel, of Madison, Wis.), tetanus (by Dr. James M. Anders, of Philadelphia), gonococcus infections (by Dr. Rufus I. Cole, of Baltimore), leprosy (by Dr. Isadore Dyer, of New Orleans), tuberculous disease (by Dr. Edward R. Baldwin, of Saranac Lake, N. Y., Dr. W. G. MacCallum, of Baltimore, and Dr. Lawrason Brown, of Saranac Lake, N. Y.), syphilis (by Dr. William Osler, of Oxford, England, and Dr. John W. Churchman, of Baltimore), and infectious diseases of doubtful nature, including febricula, glandular fever, infectious jaundice, miliary fever, Rocky Mountain spotted fever, psittacosis, foot and mouth disease, and milk sickness (by Dr. Thomas R. Boggs, of Baltimore).

Concerning the contention as to the identity of human and bovine tuberculous disease, Dr. Baldwin says conservatively: "Out of much strife the truth seems to be emerging in favor of an intermediate position between the standpoint of those who hold the belief in strictly distinct varieties and those who take an absolute unity for all." Elsewhere he cites the findings of Thorburn Smith, Ravenel, and the United States Bureau of Animal Industry as "a

tending to show that bovine infection is not unimportant for man." Dr. Baldwin adduces weighty reasons for believing that the direct transmission of tuberculous disease from parent to child must be very infrequent and practically always proceed from the mother. He adds: "Atavistic inheritance of the bacilli from the grandparents is wholly conceivable." Dr. Brown thinks that for diagnostic purposes tuberculin should be used only as a last resort, when the physical signs are indefinite and no bacilli can be found in the sputum. He regards Koch's original tuberculin as the best form for use. He speaks very guardedly of the ophthalmic tuberculin test. The pasteurization of milk to prevent inoculation, says Dr. Brown, is "much opposed" by von Behring on the ground that it "alters the immunizing qualities of the milk from immunized cows." If the author has an opinion of his own on this subject, he does not give it, so far as we have observed. It seems to us that the following are words of wisdom: "There is no more important factor in the treatment of cough than its proper discipline, first advocated by Galen. The patient should have fully explained to him that it is not necessary to raise the sputum from the lungs, for cilia are provided for that purpose, and every cough is an act of exertion and may further injure the lungs. The amount of exercise entailed in coughing should be made clear. Cough often begets cough, and a tendency once repressed may mean escape from a violent attack." The opsonin doctrine seems to be regarded as still *sub judice*. In the main, the whole subject of the treatment of tuberculous pulmonary disease is admirably handled.

The subject of syphilis is treated of at considerable length and very judiciously by Dr. Osler and Dr. Churchman. They accept the existence of parasymphylis and regard tabes as its type, though they do not appear convinced that tabes is always of syphilitic origin. The matter of preventing the spread of syphilis by the regulation of prostitution is considered in a masterly manner; indeed, what the authors say about it is among the most valuable contributions to the literature of the subject that we have ever seen.

Part II opens with an admirable chapter by Dr. Thomas R. Brown, of Baltimore, entitled *The Mechanics of Respiration and of the Respiratory Diseases*. The remaining chapters are on diseases of the nasopharynx, pharynx, and tonsils (by Dr. Francis R. Packard, of Philadelphia), hay fever (by Dr. W. P. Dunbar, of Hamburg), diseases of the larynx (by Dr. H. S. Birkett, of Montreal), diseases of the bronchi (by Dr. A. McPhedran, of Toronto), diseases of the lungs (by Dr. Hobart Amory Hare, of Philadelphia), diseases of the pleura (by Dr. Frederick T. Lord, of Boston), pneumothorax (by Dr. Walter B. James, of New York), and diseases of the mediastinum (by Dr. Henry A. Christian, of Boston). These chapters are all good, but we have not space to go into particulars with regard to them. We must, however, express our wonder that polanfin is invariably printed with an initial capital. This leads us to remark that the volume contains many faults of expression, as they seem to us, and several verbal errors, such as "intercerebral" injections (page 87), "epididymes" (page 238), "spirochaete bacteria" (page 321) and "contract of the baine" on a

prescription on page 510). But these are only blemishes; the substance of the volume is of sterling value.

*Light and X Ray Treatment of Skin Diseases.* By MALCOLM MORRIS, F. R. C. S., Ed., Dermatologist to King Edward the Seventh's Hospital for Officers, Surgeon to the Skin Department of the Seamen's Hospital, etc., and S. ERNEST DORE, M. D. (Cantab.), Assistant in the Skin Department of the Middlesex Hospital. With Twelve Plates. Chicago: W. T. Keener & Co., 1907. Pp. 172.

This small book is intended to be a summary of the methods of application and results of Finsen's light treatment, x rays, and other therapeutic agencies which have been introduced into dermatological practice within the last few years. Although it is not indicated by the title, the work embraces radium and the high frequency currents. Only three pages are devoted to radium, and, although the names of several investigators are mentioned, the work of Abbe, who has done more in this line than any other physician in America, has been entirely overlooked. Four pages are given to the important subject of high frequency currents, in which the author makes frequent reference to Allen's book, but fails to credit the work of previous American investigators. The rest of the book is devoted to x radiation and the Finsen treatment, and contains the usual report of cases. The portraits published in connection with the case reports are not of a standard to excite admiration in this country. The book will be instructive and interesting to those who know little or nothing of the subject, but is of little practical value to those who are well acquainted with the subject or who desire to enter this field of practice. It is a well printed English book, and, with the exception of the title page, very good paper is used.

#### BOOKS, PAMPHLETS, ETC., RECEIVED

*Hypnotic Therapeutics in Theory and Practice.* With Numerous Illustrations of Treatment by Suggestion. By John Duncan Quackenbos, A. M., M. D., Author of *Hypnotism in Mental and Moral Culture*, etc. New York and London: Harper & Brothers, 1908. Pp. 336.

*Surgery. Its Principles and Practice.* By Various Authors. Edited by William Williams Keen, M. D., LL. D., Emeritus Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College, Philadelphia. Volume III. With 562 Text Illustrations and 10 Colored Plates. Philadelphia and London: W. B. Saunders Company, 1908. Pp. 1132.

*The Theory and Practice of Hygiene* (Notter and Firth). Revised and Largely Rewritten by R. H. First, Lieutenant Colonel, Royal Army Medical Corps, etc. Third Edition. Philadelphia: P. Blakiston's Son & Co., 1908. Pp. 993. (Price, \$7.)

#### Miscellany.

**An Appeal to the Medical Profession.**—The Medical Society of the State of New York publishes the following appeal, and asks every physician to write at once to his representatives in the Legislature, both senator and assemblyman, urging opposition to these measures:

#### AN APPEAL TO THE MEDICAL PROFESSION.

There are now in the Legislature not less than three bills relating to vivisection and one relating to optometry. The bills, introduced by the Antivivisection Society, from which they receive their name, are formulated to prohibit animal experimentation. The statement is made that all such experiment is unnecessary and that the various

discoveries of science made possible by this method of investigation have not been productive of good to humanity. This assertion is proved incorrect by a plain statement of the facts from gentlemen of education, intelligence, and scientific attainment, professors in our various colleges, and scientists generally whose very names are synonymous with honor and integrity. They clearly show to any unprejudiced mind the inestimable value to humanity of the work which has been done, and is being done, along this line. The statement has been made that at present there is no restriction whatever placed by law on animal experimentation, whereas the fact is that there is now a law on the statute books which restricts the work to properly equipped institutions. If there have been isolated cases of violation of this law which have gone unpunished, the blame should be placed on those authorized to secure the law's enforcement. The assertion that great cruelty is inflicted on animals in these scientific experiments is denied absolutely and entirely by those in charge of experimental work in this State. There is really no reason for any enactment of a new law on this subject, and this should be made very clear to the members of the Legislature.

The optometry bill is the old measure, and should be defeated. This bill defines the practice of optometry as the measurement of the powers of vision and the adaptation of lenses for the aid thereof, all without the use of drugs. This bill gives authority to opticians to do the work, and at the same time prohibits the employment of the means necessary to do it. This bill authorizes opticians to adapt lenses to eyes for defects of vision which may be due to diseases in other parts of the body, and to diseases which may be situated in the eyes themselves. The adaptation of lenses to eyes under such circumstances, while improving vision for the time, may be the cause of deferring proper treatment until blindness or even death may be the result. To determine when defects of vision are due to defects in the eyes, or to diseases, requires the ability to make a distinctive diagnosis, and this knowledge can only be acquired, according to the laws of the State of New York, by four years' study in a medical college. Possibly some restrictions ought to be placed on the work opticians should do, but to give them the power this bill would confer would be to expose the people of this State to perils the members of the Legislature cannot have knowledge of unless we inform them.

The members of the Legislature are honest, sincere men, and their desire is to do what will be in the interest of the State. They listen with great courtesy to the expressed opinions of the medical profession, and it will require conclusive evidence on the part of opticians and others to convince the Legislature that any of these bills are necessary, or even safe, if we in good faith urge disapproval of them.

Will you not therefore at once do what you can in aiding us in defeating these measures, by writing the members of the Legislature that they may be able to act intelligently.

**Medical Onomatopoeia.**—Dr. H. C. Muller, of Utrecht, Holland, who has written many scientific works on classical philology and also on and in living Greek, is contributing a series of articles on Medical Onomatopoeia in *de Nederlandse Courant voor het Koninkrijk der Nederlanden*, with the co-operation of Dr. Rose, the first of the articles of Dr. Muller, *Bijdragen tot Hervorming der Geneeskundige Vaktaal* (contributions to the formation of medical technical language), appearing on November 10, 1907. It deals on psychical terms found in the writings of Hippocrates and Zichon. Dr. Muller gives a number of words like psychosis, the meaning of which has been changed in such a manner that the Greeks must be at loss to recognize what they shall signify. As a matter of course he also criticizes the use of *bastard words* (*Chimera*, *aphrodisia* or hybrid or bastard terms). It is highly interesting and important to study this critic's writings, because of his point of view, a physician is first made aware of cross-words and knows as well

as of living Greek, but who is not a medical man. In his letter to Dr. Rose he acknowledges the difficulty he experiences to study medical nomenclature without cooperating with a physician.—*Postgraduate*, December, 1907.

## Official News.

### Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and typhoid fever reported to the Surgeon General, Public Health and Marine Hospital Service, during the week ending February 14, 1908:

Location	Smallpox	Yellow Fever	Cholera	Typhoid Fever
Alabama—Mobile	Jan. 20	1	1	2
California—San Francisco	Jan. 23	1	1	13
Colorado—San Antonio	Jan. 24	1	1	1
Florida—St. Petersburg	Jan. 24	1	1	6
Georgia—Savannah	Jan. 24	1	1	1
Illinois—Chicago	Jan. 24	1	1	2
Indiana—Indianapolis	Jan. 24	1	1	1
Iowa—Des Moines	Jan. 24	1	1	1
Kansas—Topeka	Jan. 24	1	1	1
Michigan—Detroit	Jan. 24	1	1	3
Minnesota—St. Paul	Jan. 24	1	1	4
Mississippi—New Orleans	Jan. 24	1	1	1
Montana—Helena	Jan. 24	1	1	1
Nebraska—Omaha	Jan. 24	1	1	1
Nevada—Carson City	Jan. 24	1	1	1

BULLARD, J. T., Acting Assistant Surgeon. Granted leave of absence for thirty days from February 14, 1908.

COLLINS, G. L., Assistant Surgeon. Granted leave of absence for seven days from January 28, 1908, under paragraph 189, Service Regulations.

DUKE, B. F., Acting Assistant Surgeon. Granted leave of absence for twenty days from January 6, 1908, on account of sickness.

EAKINS, O. M., Acting Assistant Surgeon. Granted leave of absence for thirty days from April 10, 1908, and excused from duty for a further period of two months, without pay, from the expiration of said leave.

EARLE, B. H., Passed Assistant Surgeon. Granted extension of leave of absence for eight days from February 11, 1908.

FOSTER, M. H., Passed Assistant Surgeon. Directed to proceed to Ponce, P. R., for special temporary duty; upon completion of which to rejoin his station at San Juan, P. R.

FRANCIS, EDWARD, Passed Assistant Surgeon. Granted extension leave of absence for seven days from February 8, 1908.

GUITERAS, G. M., Surgeon. Directed to proceed to Fort Arthur, Texas, for special temporary duty; upon completion of which to rejoin his station at Mobile, Ala.

KEATLEY, H. W., Acting Assistant Surgeon. Granted leave of absence for one day, February 4, 1908, under paragraph 210, Service Regulations.

LAVINDER, C. H., Passed Assistant Surgeon. Granted an extension leave of absence for ten days from February 14, 1908.

McKAY, M., Pharmacist. Granted leave of absence for thirty days from March 1, 1908.

MILLER, CHARLES, Pharmacist. Temporarily relieved from duty at the Marine Hospital in San Francisco and directed to report to Passed Assistant Surgeon Blue, San Francisco, Cal., for special temporary duty.

MULLAN, E. H., Assistant Surgeon. Granted leave of absence for one day, January 4, 1908, under paragraph 191, Service Regulations; granted leave of absence for seven days from January 29, 1908, on account of sickness.

PARKER, H. B., Passed Assistant Surgeon. Granted leave of absence for five days from January 27, 1908, on account of sickness.

RAMUS, CARL, Passed Assistant Surgeon. Granted leave of absence for three months and twenty-three days from March 1, 1908, with permission to go beyond the sea.

ROBERTS, N., Assistant Surgeon. Granted leave of absence for six days from February 3, 1908, under paragraph 191, Service Regulations.

THOMPSON, W. R. P., Acting Assistant Surgeon. Granted leave of absence for twelve days from January 10, 1908.

WARD, W. K., Passed Assistant Surgeon. Granted leave of absence for one day from January 3, 1908, under paragraph 191, Service Regulations.

WARREN, B. S., Passed Assistant Surgeon. Relieved from duty at Chicago, Ill., and directed to proceed to St. Louis, Mo., and assume command of the Service at that port.

WOLLENBURG, R. A. C., Assistant Surgeon. Granted leave of absence for seven days from January 2, 1908, under paragraph 191, Service Regulations.

#### Board Convened

A board of medical officers was convened to meet at Fort Townsend Washington, February 14, 1908, for the purpose of making a physical examination of an officer of the Revenue Cutter Service, to determine his fitness for promotion. Detail for the board: Surgeon W. G. Stimpson, chairman, and Passed Assistant Surgeon J. H. Oakley, recorder.

#### Army Intelligence:

*Official list of changes in the stations and duties of officers serving in the medical department of the United States Navy for the week ending February 15, 1908.*

DAVIS, W. T., Captain and Assistant Surgeon. Leave of absence extended five days.

FLAGG, C. F. R., Captain and Assistant Surgeon. Assignment to duty in the Philippine Islands revoked.

GRAY, W. W., Lieutenant Colonel and Deputy Surgeon General. Relieved from duty as chief surgeon and attending surgeon, Department of the Gulf; ordered to proceed to the Philippine Islands, and upon arrival at Manila to report in person to the commanding general, Philippines Division, for assignment to duty.

SHIMER, I. A., Captain and Assistant Surgeon. Orders so amended as to direct him, on arrival at San Francisco, Cal., to report for duty as surgeon of the Transport *Crook*. Upon arrival at Manila, Captain Shimer to report in person to the commanding general, Philippines Division, for duty as heretofore ordered.

#### Navy Intelligence:

*Official list of changes in the medical corps of the United States Navy for the week ending February 15, 1908:*

BROWN, E. M., Passed Assistant Surgeon. Detached from the Naval Hospital, New Fort Lyon, Colo., and ordered to report at said hospital for treatment.

FAUNTLEROY, A. M., Passed Assistant Surgeon. Detached from the Naval Hospital, Mare Island, Cal., ordered home, and granted leave for two months.

### Births, Marriages, and Deaths.

#### Married.

CARR—ASHLEY.—In Wilkesbarre, Pennsylvania, on Wednesday, February 12th, Dr. Charles D. Carr, of Philadelphia, and Miss Sophia E. Ashley.

CULLER—LOSER.—In Philadelphia, on Wednesday, February 12th, Dr. Robert M. Culler, United States Army, and Miss Anna E. Loser.

SAXE—BAER.—In New York, on Thursday, February 20th, Dr. G. A. De Santos Saxe and Miss Laure Baer.

#### Died.

BADGER.—In Flushing, New York, on Thursday, February 13th, Dr. William Badger, aged seventy-four years.

BALDWIN.—In Newark, New Jersey, on Sunday, February 9th, Dr. Aaron K. Baldwin, aged sixty years.

BEST.—In Brucetown, Fredonia County, Virginia, on Wednesday, February 5th, Dr. William J. Best, aged seventy-five years.

BIRKHOFF.—In Chicago, Illinois, on Sunday, February 9th, Dr. David Birkhoff, aged fifty years.

DALTON.—In Tryon, North Carolina, on Tuesday, February 4th, Dr. Martin J. Dalton, of Melrose, Massachusetts, aged forty-eight years.

DANZIGER.—In Cincinnati, Ohio, on Friday, February 14th, Dr. Leo Danziger.

EGGLESTON.—In Worsham, Prince Edward County, Virginia, on Tuesday, February 11th, Dr. Joseph Dupuy Eggleston, aged seventy-six years.

GOLDSBOROUGH.—In Walkersville, Frederick County, Maryland, on Thursday, February 6th, Dr. Charles W. Goldsborough, aged sixty-seven years.

GROSS.—In Philadelphia, on Saturday, February 8th, Dr. William Dana Gross, aged forty-six years.

HEGEMAN.—In Troy, New York, on Wednesday, February 12th, Dr. William H. Hegeman, aged eighty-one years.

HEINEMAN.—In Paris, France, on Tuesday, February 11th, Dr. Henry Newton Heineman, aged fifty-five years.

HULLHORST.—In Lincoln, Nebraska, on Friday, February 7th, Dr. Charles G. A. Hullhorst.

LADLEY.—In St. Louis, Missouri, on Wednesday, February 5th, Dr. Leonidas H. Ladley, aged sixty-four years.

MOSS.—In Morgan Hill, California, on Tuesday, February 4th, Dr. Frank Hayden Moss, aged forty-three years.

PORTER.—In Wardsenville, Hampshire County, West Virginia, on Thursday, February 6th, Dr. Hampton Porter, aged seventy-two years.

PUTNAM.—In Lyons, New York, on Sunday, February 9th, Dr. J. W. Putnam, aged sixty-one years.

RICHARDSON.—In Buffalo, New York, on Wednesday, February 5th, Dr. Charles C. Richardson.

SCHLEY.—In New York, on Saturday, February 8th, Dr. Fayette E. Schley, aged fifty years.

TIEFENTHALER.—In Washington, D. C., on Thursday, February 6th, Dr. Benjamin F. Tiefertalher, aged thirty-nine years.

WILLIAMSON.—In Malone, New York, on Wednesday, February 5th, Dr. Stacy Dwight Williamson.

#### THE AFTER CARE OF THE INSANE.\*

By FREDERICK PETERSON, M. D.,  
New York,

Ex-President of the New York State Commission in Lunacy; Professor of Psychiatry, Columbia University.

In the ten minutes permitted me for the discussion of this particular type of care of convalescents, I can only briefly cover what has been accomplished in the matter of after care of the insane at home and abroad. At a recent dinner I heard a pessimist say that in almost everything relating to social organization the United States are at least fifty years behind Europe, and in the indignant discussion which followed I am afraid I had rather the best of the argument. However, it was generally agreed that no other country is so quick as ours to remedy its defects when once clearly recognized.

The circumstances surrounding insanity are very different from those associated with other forms of illness. Insanity is a protracted malady, and convalescence and cure are matters of months or even years after admission to hospitals. When the poor and friendless insane are finally discharged they come almost as strangers into the community and are often wrongly regarded, if their history is known, with some degree of suspicion, even apprehension. To have been in a hospital for the insane, even if now fully restored to health, is unfortunately looked upon as a handicap. By long sequestration one loses touch with old associates and feels among his former haunts like Rip Van Winkle after his sleep of twenty years. These conditions favor the recurrence of his malady. Then, too, the number of convalescent and cured insane is much larger than we ordinarily realize, and, as most of the hospitals for the insane are in the country far from civic centres, few of us know that their total population is about 27,000 in the State of New York alone. And when we consider that their mental disorder has often been the result of conditions of struggle and stress in the maelstrom of our social life, and that they must return to a similar or perhaps harsher environment, less well equipped for the battle because of the tragic infirmity they have suffered, we can readily see that an aid society for the recovered insane must make an especial appeal to our sympathies and take high rank among after care institutions.

I believe that it was nearly two hundred and twenty years ago that the first after care institution of any

kind was established, and this was in France for the benefit of convalescents from general hospitals. But it was almost two centuries later before it occurred to any one that an organization for the care of the convalescent and recovered insane would be a project worthy of our interest and consideration. It was a German who originated the first society for the help and protection of the recovered insane in 1829, followed twelve years later by the establishment of a similar society in France, and thirty years later by a Guild of Friends of the Infirm in Mind in England. Very soon after this there were in existence numerous active societies for the care of the convalescent insane in Germany, France, Austria, England, Switzerland, and Italy.

The first suggestion for creating societies of this kind in the United States seems to have come from Dr. P. M. Wise, formerly president of the State Commission in Lunacy of New York, in 1893, in a paper read before the American Medicopsychological Association, and in 1894 Dr. Henry R. Stedman, of Boston, read a paper entitled Management of Convalescence and the After Care of the Insane before the American Neurological Association. On the motion of Dr. C. L. Dana at this meeting a committee consisting of Dr. Stedman, Dr. Dana, and Dr. Dercum was appointed to investigate and report upon some feasible plan for the aid and supervision of the convalescent insane poor during the first month or two after their discharge from asylums. The report of the committee was published in the transactions of the association in 1897. There was an interval of several years before the after care idea had any further development in this country. In the meantime, Japan, always quick to adopt anything practically helpful from our western civilization, established an aid society for the insane in 1902.

Miss Louisa Lee Schuyler, of the New York State Charities Aid Association, who has done so much for the insane and epileptic, may be described as the founder of the first after care organization in this country, and it is owing to her efforts, combined with those of the superintendents of the State Hospitals for the insane, that an organization for after care of the insane in the State of New York was established in February, 1906, through the Committee on the Insane of the State Charities Aid Association. A subsequent amendment to the original act provides for an after care committee to be appointed by the State Charities Aid Association in each hospital district in the State. Already five of the State hospital districts have such after care committees, and the reports of what has already been done are very gratifying. The cause has been furthered very largely by the excellent papers of Dr. Kahlili

\*Read before the Section in Public Health of the New York Academy of Medicine, January 24, 1908.

Dewey in 1905 and of Dr. Adolf Meyer, Dr. William Mabon, and Dr. Robert M. Elliott in 1906 and 1907.

The rather unusual needs of the insane, as compared with the needs of other convalescents, has led of late to some extension of the functions of an after care society, so that the qualification "after care" does not fully represent our present conception of such an organization. This evolution of a new and larger ideal of work to be accomplished is due in great part to the suggestive papers of Dr. Adolf Meyer. Indeed, the old English designation, Guild of Friends of the Infirm in Mind, would better describe the present trend of combined efforts in this direction. It is hoped that the hospital physicians themselves will become members of the various after care committees, not only for the purpose of following up and aiding their recovered patients by wise counsel, but in order to better study the milieu in which the mental disorder arose, to better aid in the fight against the preventable causes of insanity. Take but one preventable cause, alcohol. How few realize that 5,400 of the present inmates of asylums in New York State alone owe their insanity to alcohol!

A guild of this kind composed of hospital physicians, local practitioners, lawyers, clergymen, business men, and their wives, as they become familiar with all matters pertaining to the insane through their relation to the immediate objects of after care, will diffuse ideas of prophylaxis through the community and educate the people in this important department of public health. Not only will preventable causes thus be more generally recognized and more strongly combatted, but the public will become more alive to the need of early treatment and take advantage of the opportunities now afforded for medical advice in mental disorders at outdoor departments of city clinics and country asylums. Fore care as well as after care of the insane is therefore one of the new features in connection with the type of institution under discussion here to-night.

#### CONSERVATIVE PROSTATECTOMY.\*

BY FOLLEN CABOT, M. D.,

NEW YORK.

Attending Genitourinary Surgeon, City Hospital; Professor, Genitourinary Diseases, Postgraduate Medical School and Hospital; Consulting Urologist to White Plains Hospital.

During the past few years much progress has been made in the treatment of prostatic hypertrophy. The advancement has been mainly along surgical lines. The mortality of 18 to 25 per cent. of ten years ago has been gradually reduced, till now it averages about 7 per cent. The results of the operation as to the urinary function, etc., have also shown much improvement. In my own series of seventy-two complete prostatectomies performed in the past five years I have lost five patients. Two of these were diabetics and the others were worn out from long suffering. In looking back over these deaths I believe, with my present experience and change in methods, I could have saved at least three of these men.

I have divided prostatitis into three groups.

1. In the first group I have placed the cases which are beginning to show evidence of prostatic obstruction. There is usually no appreciable residual urine, but the force of the stream is somewhat diminished, mild straining, increase in time of emptying bladder and some increase in frequency of urination. The patient probably rises twice during the night to empty his bladder. This fact may be the cause of his seeking his physician. Upon rectal examination we find as a rule some increase in size of the prostate. This change, however, may not be appreciable even to the trained finger. The increase in prostatic growth may be entirely vesical. By the careful employment of clean, flexible catheters and sounds the urethra may be searched for stricture. I have, however, never seen a stricture in a case of prostatic hypertrophy. The use of instruments may do harm unless handled with every care. The general condition of the patients in this first division is not materially affected.

2. In the second group I have placed those patients who have two or more ounces of residual urine, who are straining considerably, and getting up four to five times at night to empty the bladder. There is much falling off in the force of the stream and it may even not go beyond the shoes, but almost dribble away in some cases. As a result of the broken sleep and also usually cystitis and pain, the general health soon becomes involved. Slight exposure to cold, dampness, indiscretion in diet and use of alcohol will all aggravate the symptoms, and may even cause retention which necessitates use of the catheter for its relief. If the obstruction has been present for some time there is usually cystitis, and often in addition pyelitis.

Rectal examination nearly always reveals increase in size of the prostate. The enlargement, however, may be almost entirely vesical. The urinary distance as measured by the catheter is nearly always increased. In some of my patients a cystoscopic examination has been of value in determining the condition of the bladder, presence of stone, diverticula, and prostatic bulging. On the whole, though, I have been somewhat disappointed in this method

\*Read before the Medical Association of the Greater City of New York, January 20, 1908.

of diagnosis and do not use it except in my perineal cases.

3. In the third group I have placed those prostatics who can no longer be treated by palliative measures. They are usually very much shattered in health and will not withstand much surgical shock. The catheter no longer gives relief, but often is the cause of hæmorrhage, chills, and pain. The patient is in constant distress, night and day. The cystitis is of a severe grade, and occasionally there is stone in addition to the enlarged prostate. In many cases there will be a steady overflow and dribbling of urine. Bladder instrumentation is usually out of the question, and yet some relief must be given. There is nearly always a pyelitis and often a pyelonephritis.

By rectum we usually find a large prostatic overgrowth. Manipulation by the finger produces much pain as the prostate is pressed. This, no doubt, is due to the additional engorgement of the organ as a result of straining and inflammation. Hæmorrhoids, often very large, are common, and even prolapse of the rectum, as a result of efforts to empty the bladder.

A man's age really has little to do with his power to resist operative shock. The circulatory apparatus, kidneys, and general condition must, however, be carefully studied in every instance.

In the first group of prostatics, those in good health, with mild symptoms, no operation is advisable unless there is evidence of advance in the obstruction. This is shown by more frequent urination and straining on passing water. These patients, therefore, should be carefully watched for any evidence of advance in the process. Their lives should be carefully regulated. Medicine is usually of no use except in instances of infection, when urotropin is of value. The bladder may also be washed out two to three times a week. If, however, the disease shows a well marked tendency to advance, an early operation should be performed. It is much more conservative to advise it before the machinery has become impaired. It is easier for the patient and surgeon. We are now seeing these patients earlier in their disease, and, as a result, mortality is lower. This fact, combined with improved technique and better understanding of preliminary and after treatment, has placed surgery of the prostate in a very satisfactory state. Formerly no cases were operated on till the condition was well advanced into the second and even third group. The mortality therefore was necessarily high, and the operation often done as a last resort.

When a patient suffering with mild obstruction, as shown in the first group, presents himself for an opinion, and my observation convinces me that an operation will eventually be necessary, I present the probabilities to the patient and his physician. In all the cases I have operated in this group I have had uniformly satisfactory results. I am also seeing more of these cases now.

In the second group we usually have evidence of cystitis and often a secondary pyelitis. The catheter has to be used occasionally or perhaps constantly to keep the patient at all comfortable. The night is usually the worst time and although he may wear a urethral catheter he is never comfortable.

The broken rest use of catheter and all it entails

really convert the patient into an invalid. No poor man can afford it, and for any man except under peculiar conditions it is most undesirable. There are exceptional cases where proper use of the catheter and general care result in comfort and long life to the patient, but such cases are not common. There is always danger of infection and other complications which suddenly bring the patient into the third group. In this third group something of a surgical nature is necessary in order to preserve life. It often happens, too, that there can be no further delay. The question therefore arises in all cases in this group and some in those in the second one, too, what shall we advise? A complete prostatectomy is almost sure to be followed by death. My friend, Dr. Lilienthal, answered this question in 1896 by suggesting and carrying into practice a two stage operation. I have done this several times and believe it to be of the greatest value. In all cases of the least doubt of the patient's resistive power I do a two stage operation.

The patient in a state of shock or low resistive power is quickly prepared for operation. A suprapubic cystotomy is done under local or general anaesthesia. This should not take more than five to eight minutes. By this means we obtain all the advantages of a complete operation without its disadvantages. The patient is put to bed wearing a good sized drainage tube. He is made to sit up at the end of twenty-four to forty-eight hours and drained in this way till his condition is so good that a prostatectomy can be quickly performed through the same cut. This drainage may continue five days to four weeks. The patient may sometimes wear the tube indefinitely.

The cystitis gradually disappears, the condition improves, the engorgement of the prostate passes away, and the patient, through rest and forced feeding, regains his lost strength. He then is given a small amount of chloroform and the prostate is enucleated in a few minutes. The only cut made at the second operation is the one about the prostate.

If the patient cannot withstand these two small operations it would have been useless to perform a complete operation at one sitting. I believe this method will be used more all the time, and will further reduce the mortality.

The suprapubic route is the best one for this two stage operation, owing to the comfortable position of the tube.

There has been much discussion as to the best operative route. In my opinion the perineal is better in certain simple cases of a small prostate low down, while in the majority of instances the suprapubic route is the most satisfactory. We are better able to control hæmorrhage, dress the wound, and also, I believe, obtain better urinary results. The convalescence is, however, somewhat longer, and there is a little more shock than noted in perineal route. However, with the two stage method, a divided operation does away with the latter objection. I believe also it will make the various cauterizing operations unnecessary.

The question of the result in the sexual power has also been much discussed, and, I believe, exaggerated. I have never had but one man complain of loss of sexual power in my list of seventy-two

cases. It is usually much reduced before operation and causes no particular concern after it. In fact, I believe, with the operative results otherwise very satisfactory, we need pay no attention to the sexual side.\* In one case of perineal prostatectomy the man said he felt stronger in sexual power.

In closing I will give the history of a case operated on by the two stage method:

CASE.—This patient, referred to me by Dr. Hopke, of Brooklyn, was operated upon in December, 1906. He was seventy-five years old and had been suffering from symptoms of prostatic obstruction for twenty-five years. General condition was bad; irregular heart; well marked arteriosclerosis. Digestive system was in fairly good condition, some albumin and few casts in urine showing evidence of renal irritation as result of back pressure. There was very severe cystitis, alkaline urine with well marked ammoniacal decomposition. Urinating six or seven times at night and each hour or less in day till catheter life was begun shortly before I saw him. Residual urine, 14 oz. Urinary distance somewhat increased and prostate, by rectal touch, high up and difficult to reach. It was apparently not very large and felt smooth and firm. Recently patient complained of chills and had reacted badly to bladder irrigation, but had never passed much blood.

Owing to the patient's enfeebled condition and severe cystitis it seemed best to operate by two stages, and so I performed a suprapubicotomy under light chloroform anesthesia, it being thought best not to give nitrous oxide. The bladder was opened under air dilatation and tube of 44 French calibre introduced. The prostate and bladder were also carefully palpated, all of which took eight minutes. The third lobe or isthmus was hypertrophied and caused the difficulty. The rubber drainage tube was kept in place with a Bang's shield and the patient put to bed.

The old gentleman quickly recovered from the anesthesia. Strychnine sulphate gr. 1/30 each three hours was administered, also small quantities of soft, uncharged water were soon taken at frequent intervals. The latter was given to stimulate the kidneys. While the pulse never went over 100 and the temperature remained at about 99.5° F., there was considerable prostration the following day. However, in forty-eight hours the patient rallied well, and on the third day sat in a chair for an hour or two. Bladder was washed frequently with boric acid and saline solution. Cystitis gradually improved with addition of urinary antiseptics and acids to correct alkaline reaction. In about two weeks the patient was walking about and going downstairs to his meals. At the end of three weeks the urine was clear and free from albumin. He was in much better condition than he had been for several years. I then, without telling him that the operation had not been finished, operated again through same cut under chloroform, and in nine minutes removed the prostate. During the enucleation a catheter was introduced through the penis, hot saline solution was continually run into bladder and at the end of the operation several ounces of solution of adrenalin 1/3000 was introduced. There was a very small amount of hæmorrhage. The congestion about the prostate had disappeared during the period of rest and so there was less blood in and about the gland. The enucleation was carried out so that the whole prostate was removed in one piece. The prostatic capsule was packed with a strip of gauze which had been soaked in adrenalin 1 in 3000. The urethral catheter was left in place behind the packing to use for adrenalin in case of hæmorrhage and later, after the gauze was removed at end of forty-eight hours, for inlet to irrigation. The large tube in the suprapubic wound was for outlet to fluids.

The patient seemed to have less prostration following this final operation than he did from the preliminary one. I attribute this fact to his improved condition as a result of good drainage of bladder, rest, and nursing for three weeks. In three days he was up and at the end of seven days both tubes were removed. During the healing of wound a small catheter was daily passed into the bladder through wound and the cavity irrigated. In fourteen days the wound had completely closed and the patient was soon passing urine in a very satisfactory manner. The control was good from the first, as it usually is when the operation is performed suprapubically. After this time no further irrigation was em-

ployed and no urethral sounds passed at any time. It does not as a rule seem to be necessary unless there is some complicating condition in the urethra which needs it. Stricture, however, in my experience, is rare in prostatics. In June the patient reported himself in fine condition, was back at work, had no urinary symptoms, emptied his bladder completely and felt better than he had for twenty-five years.

## THE GASTROINTESTINAL SYMPTOMS OF MIDDLE EAR SUPPURATION.\*

By LOUIS FISCHER, M. D.,  
New York,

Attending Physician to the Children's Department of the Sydenham Hospital, and to the Willard Parker and Riverside Hospitals, etc.

When a child presents gastrointestinal symptoms one would naturally infer that the stomach or the intestines are the seat of the trouble. We must remember, however, that very many diseases are ushered in by vomiting, others by vomiting and diarrhœa, so that a careful distinction of the ætiological factor is demanded.

Vomiting and fever occurring in the preeruptive stage of scarlet fever has many times been diagnosed as a spoiled stomach. The careful inspection of the throat would have solved this mystery. Such serious mistakes may mean an exposure in school or home of healthy children to one of the worst infectious disorders of infancy and childhood. Vomiting is an early symptom in tuberculous meningitis, therefore a symptom that assumes greater dignity because it may mean an initial manifestation of any one of several disorders. In like manner an infection of the middle ear, be it due to the streptococcus or to the pneumococcus, frequently causes gastric or gastroenteric disturbances. The gastric symptoms, *per se*, be they vomiting, anorexia, or meteorismus, are simply toxic manifestations of the otic infection, and they are really the result rather than the cause of the trouble.

Secretions from the rhinopharynx in a young child are never expectorated, but invariably swallowed. Such discharges may increase the severity of the gastric symptoms. Kossel found that in a case of otitis infection due to *Bacillus pyocyaneus*, the same bacteria were found in the stomach as were found in the middle ear.

Pathogenic bacteria lie dormant in the mouth and in the rhinopharynx. They gain entrance to these parts first by the air, second through faulty hygiene. One of the most frequent means of introduction of pathogenic bacteria is the common nipple used to soothe the baby while crying.

Preysing<sup>†</sup> studied a series of 121 infected ears. He found a pneumococcus infection in 112 cases, or 92.5 per cent. This alone forced Preysing to believe that otitis media in nurslings is a specific entity due to a pneumococcus infection.

Zaufals found that we are dealing with a primary otitis due, according to him, to the pneumococcus infection, whereas the secondary infections

\*Read, by invitation, at a symposium on middle ear suppuration, before the Eastern Medical Society, January 10, 1908.

<sup>†</sup>Preysing: *Otitis Media in Säuglinge*, 1904.

are caused by the streptococcus. He then divides the primary conditions into those following exposure to cold and benign catarrh. In secondary cases, those following scarlet fever, measles, diphtheria, and typhoid. Influenza is looked upon as one of the most frequent causes of otitis by Gomperz.

Rasch<sup>2</sup> found the pneumococcus in thirty-three cases of mucus exudate out of a series of forty-three examined by him. Leutert<sup>3</sup> found in a study of the bacteriology of otitis in small children that when a tendency to empyema was found, then the streptococcus was the causative factor, so that it would seem that the streptococcus was demonstrated more often in those cases leading to an empyema, whereas the pneumococcus was found in the milder type of middle ear inflammation.

Weiss not only studied the superficial bacteria, but also studied sections of tissue to see how deep the bacteria penetrated. He found the *Diplococcus pneumoniae* in 42 per cent., the *Streptococcus pyogenes* in 39 per cent., the *Staphylococcus albus* in 27 per cent., the *Staphylococcus aureus* in 12 per cent. His cases were as young as twenty-five, thirteen, eleven, and two days old. Gomperz<sup>4</sup> believes that otitis is more frequent following influenza than it is in any other infectious disease.

**Method of Infection.**—Pathogenic bacteria can enter with air and nasal secretions through the nose into the Eustachian tube. In like manner an infection can take place from the pharynx or by infectious secretions from the bronchi. During the act of vomiting it is easy for pathogenic bacteria to gain entrance through the Eustachian tube in the rhinopharynx. The act of sneezing, yawning, coughing, swallowing, and muscular action associated with regurgitation of food, especially while the child is in the dorsal position, are all conditions which should be remembered in seeking the source of an infection. The ease with which nurslings vomit seems to call for especial stress. Fluids will frequently be expelled through the mouth and nose. If, therefore, the nose is obstructed by accumulated secretions, and there is a damming back of decomposed food in the rhinopharynx, bacteria if present can be forced easily into the Eustachian tube.

Netter<sup>5</sup> examined thirty-one cases post mortem and found that out of these, twenty-eight cases of otitis were caused by the pneumococcus. Kossel,<sup>6</sup> in studying nurslings with special reference to middle ear inflammation, found that out of 108 cases in the institute for infectious diseases in Berlin, eighty-five had inflammation of the middle ear; thirty-eight of these were carefully studied bacteriologically; half of these contained a bacillus resembling Pfeiffer's pseudoinfluenza bacillus. In ten cases he found Fränkel's pneumococcus, in four

staphylococcus, in two cases streptococcus and Friedlander's pneumonia bacillus. Once he found tubercle bacillus, also once *Bacillus pyocyaneus*. The same pathogenic bacteria found in broncho-pneumonia were also found in the middle ear. In thrombosis of the cerebral sinus he found the Friedlander's pneumonia bacillus. In the pyocyaneus infection, the same bacteria were found in the stomach, and thus gave rise to vomiting and diarrhoea.

Diarrhoea may be due to Nature's method of eliminating poisons stored in the body. If a child suddenly shows gastric disturbances and if the food suddenly disagrees, then the temperature should be taken. In addition to the careful examination of the stomach and intestines, the nose and throat should be examined. No diagnosis should be considered complete until the throat, and especially the ears, have been examined. The symptoms of an otic infection may so resemble an acute milk infection that only careful examination of the ears can determine the correctness of such diagnosis.

The gastrointestinal symptoms due to the toxæmia resulting from a pneumococcus infection or a streptococcus infection of the middle ear appear in the following manner:

**Breast Fed Infant.**—There is usually a history of some member in the family having had the grippe. The infant up to this time had been enjoying excellent health. It is suddenly taken sick. The human milk causes dyspeptic symptoms, such as vomiting, diarrhoea, greenish or curded stools, and anorexia. The infant turns away from the breast, and the mother in her anxiety to feed the baby commits the dietetic error of too frequent feeding. Accompanied by these symptoms there is a marked febrile disturbance. The temperature may be 101° F. and rise to 104° F., or even 105° F. The pulse rate is accelerated and may reach 130 or 140. The pulse never intermits as it does in tubercular meningitis. The respiration is also increased, and is usually between 30 and 40 per minute. There is no cough present, and there are no distinct evidences of pulmonary involvement. The surface of the skin feels hot, and the head is flushed. At times an erythematous or an urticarial eruption will be found on various parts of the body, chiefly confined to the face, thorax, and abdomen. This punctate eruption lasts from three to four days. The infant has a marked apathetic condition and moans at times as though in pain. The stomach and abdomen appear distended, and percussion shows marked meteorismus. The flatulence is also evident by frequent eructations as well as by the expulsion of flatus. The tongue is coated with a whitish fur. The pharynx and tonsils appear red and congested, but there are no visible patches. There is a marked odor of acetone perceptible from the breath. The cervical glands are not involved.

**Bottle Fed Infant.**—The clinical manifestations in an infant, brought up artificially, are usually more intensified. The same clinical picture of illness, vomiting, fever, and gastroenteric disturbances will also be found. In addition thereto the temperature may reach 105° F. at the very beginning, and the symptoms may be ushered in by convulsions. There

may be grinding of teeth. The stools, which until now have been of a uniform consistency, show evidences of enterocolitis. They are either green or muddy and contain mucous and undigested particles of food, and are foul smelling. They are accompanied by large quantities of gas. From the irritation of these acid stools there may be an excoriation around the anus and the buttocks are usually red and inflamed. The urine shows a high gravity and acetone in addition to quantities of indican, the latter indicating a disturbance of metabolism due to putrefactive absorption. The gastric symptoms will continue in spite of careful dieting. So, also, undigested particles of food will be found in the stool, showing the effect of the toxine on the glands of the stomach and intestines. When intestinal digestion is impaired, in spite of eliminative treatment and careful dieting, it proves that the seat of the trouble is located elsewhere. An examination of the blood in a doubtful case of prolonged fever may at times reveal obscure suppuration. If the polynuclear percentage is very high then it speaks for the presence of pus. The fever curve is one that shows wide variations similar to what we find in tuberculous meningitis.

As a rule the symptoms are more pronounced in the marasmic or atrophic child. It is hardly in the province of this paper to go into the details of secondary infections resulting from the acute exanthemata further than to say that an associated ear complication must always appeal to the physician, and hence as a routine method of watching the urine is demanded, so also must the ear be carefully supervised by the attending physician or by an aurist if necessary.

In a normal infant during the act of crying or screaming the drum membrane appears pink or rose colored. It is advisable, therefore, to examine the ear gently and quickly while the infant is asleep to prevent its waking and crying.

65 EAST NINETIETH STREET.

#### INDICATIONS FOR SURGICAL INTERVENTION IN SUPPURATING MIDDLE EAR DISEASES OF INFANCY AND CHILDHOOD.\*

BY FELIX COHN, M. D.,  
New York.

The first and important surgical intervention, the performance of which it is our duty to consider in middle ear disease of infancy and childhood, is the incision of the drum membrane, or, as it has been originally designated, the operation of paracentesis. While we still abide by the old appellation, it is well to remember that the simple puncture with the so called paracentesis needle has been laid aside by most otologists, a thorough incision having proved to be the more surgical procedure and the one giving the best results.

##### *Indications for Paracentesis.*

In formulating indications for paracentesis of the membrana tympani, it is necessary to consider the character of the inflammation from every point of

view, from the pathological, bacteriological, and surgical.

The pathologist recognizes two main forms of acute middle ear inflammation, an otitis media catarrhalis simplex acuta and an otitis media acuta mucopurulenta sive purulenta. In the former the exudate is usually serous or mucous in character; in the latter the discharge is always mucopurulent or purulent. The simple catarrhal otitis represents a lighter form of inflammation; the latter a graver one. From the bacteriological standpoint this distinction does not entirely hold, as we now recognize a streptococcal form of invasion, for instance, which may give a serous exudate accompanied by complications fully as severe as the mucopurulent or purulent types of inflammation. A practical subdivision, from the surgical point of view, and usually accepted, recognizes a nonperforative and a perforative form of inflammation.

We speak of a middle ear inflammation as being perforative if a *restitutio ad integrum* is impossible without artificial or spontaneous vent having been given to the exudate contained in the tympanic cavity. The acute catarrhal inflammation is usually a nonperforative form; the exudate, generally mucous or serous in character, becomes absorbed; in the perforative form, the exudate is usually mucopurulent or purulent. If we bear in mind these facts the formulations of our indications for paracentesis are almost obvious and we can logically conclude that:

I.—*Paracentesis is indicated in every form of perforative inflammation.*—It should be our aim and it is our duty in this form of inflammation to incise the drum membrane if possible before spontaneous rupture can occur, in order to alleviate all symptoms and establish the most efficient drainage. It follows likewise that in those cases in which rupture has occurred, it is our duty to aid Nature by making an incision if there are any symptoms pointing to retention, pressure, etc.

Bearing in mind our classification it follows naturally as an absolute and obvious deduction that:

II.—*Paracentesis is not indicated in the nonperforative form of inflammation.*—The formulation of these two indications would suffice were it not for the fact that in practice we meet with a group of cases in which we unfortunately are perplexed to determine the character of the otitis, and if we question ourselves, therefore, as to the fact whether we have any absolute guide which enables us to distinguish between these forms, we must frankly confess that even the most experienced will find it impossible in every case from its inception to determine absolutely upon the character of the inflammation.

We are, therefore, compelled to add as a third indication that:

III.—*Paracentesis should be performed in every doubtful case in which distinction is impossible or difficult, and whenever immediate depletion and diminution of tension in the tympanic cavity appear advisable.* Our aim, however, should be to evolve a symptomatology which will enable us to distinguish between the various forms of inflammation,

\*Read before the Eastern Medical Society, January 10, 1908.

and reduce our third indication—a *testimonium paupertatis*—to as few cases as possible.

The fact of the difficulty in distinguishing has made the subject of indication for paracentesis a very active and mooted one in the last years, and has tended to cause a great deal of discord among otologists; we might speak to-day of two camps, those otologists who perform paracentesis too often, and those who perform paracentesis too seldom. By carefully evolving the symptomatology in every case, take cognizance of the otoscopic picture, the subjective and objective symptoms, and remembering to individualize, a happy medium between these two violent extremes ought not to be difficult to find. As a guide to the practitioner, we can state that for most otologists a trias of symptoms has been considered as an indication for paracentesis, namely, a bulging drum membrane accompanied by pain and the presence of an elevated temperature. While for most cases this trias occurring simultaneously may be considered a safe guide for the diagnosis of a perforative otitis, I have found one modification of great service in enabling me to distinguish—of course I am simply outlining in general and not any particular case. For instance, earache not readily controlled by application of heat and recurring quickly after removal of poultice or water bag, accompanied by a rise in temperature and a bulging, usually speaks for the existence of a perforative form of inflammation. On the other hand, given a child suffering from intense earache, on examination you may find a high temperature, a typically bulging drum membrane, apparently the complete trias; if you apply moist heat or a water bag the child quiets down speedily, and in a few days you find a complete restitution to the normal, a type of *catarrhal* inflammation apparently simulating a perforative form. If we therefore take into consideration this fact, that in many cases a diagnosis can only be made by a little prolonged observation and in some cases by the application of a heat test, if I may so term this symptom, we formulate naturally as our fourth indication:

IV.—*Not to perform paracentesis too early; unless some aggravating symptoms demand such interference.* Wait until the symptoms have somewhat developed. That, of course, does not mean waiting indefinitely, but waiting from hour to hour and possibly from day to day.

There is another disadvantage to paracentesis made a little too early, before the inflammation has somewhat progressed, diminution of depleting effect of operation and tendency to closure of incision before formation of discharge. In formulating the indication not to do paracentesis too early, it must be understood that the term early refers to the course of the inflammation, rather than to the actual lapse of time. In one case a paracentesis at the end of twelve hours may be late; in another a paracentesis performed on the second or third day may be considered in that individual case a fairly early paracentesis. Usually the time when a paracentesis should be performed may range from the beginning of the onset up to the second, third, or even fourth day; and a careful consideration of the *total available* will enable us to select the suitable time for the incision of the drum membrane.

I do not wish to leave this subject, which, unfortunately, the allotted time does not permit me to exhaust properly, without warning the practitioner that occasionally there are cases without any symptoms—no trias, a slight history of earache, where only a pyæmic rise of temperature points to the presence of an exudate—which, above all others, require immediate paracentesis to prevent unfortunate and even fatal complications, such as a resulting otogenic pyæmia, a complicating circumscript abscess, etc., the apparently light form of otitis having been overlooked on account of the absence of the subjective earache to which the practitioner so frequently attaches too much importance.

In the perforative forms, however, the practitioner will rarely find normal or almost normal appearance of the drum membrane. In the ordinary perforative forms, except in those rare cases in which other dangerous symptoms predominate, a paracentesis should not be made before such changes as considerable swelling or partial swelling of the *membrana tympani* is noticeable, unless a distinct exudate accompanied by febrile symptoms is present and the exudate visible through the *tympanum*. Exceptions to this are in otitis occurring in the course of the so called infectious diseases, measles, scarlet fever, etc.; early paracentesis should be the rule in order to diminish the effect of the necrobiotic changes that take place in the tympanic cavity and drum membrane, thereby mitigating the ravages otherwise caused. Paracentesis should be made at the earliest indicated occasion; even a slight boggiess of Schrapnell, without bulging of the drum membrane, should be considered enough indication for paracentesis. The resulting depletion and reduction of pressure may assist us in preventing sloughing and destruction of the drum membrane, so often the sad sequelæ of morbillic and scarlatinous inflammations.

Let me emphasize the importance of the practice of absolute asepsis in our incision. Thorough cleansing of the canal, removal of cerumen and scales, and the regular practice of the application of an occlusion bandage for several hours after paracentesis may prevent secondary infection in those cases where discharge or exudate has not yet made its appearance, and a change of what might have been a nonperforative form of inflammation into a perforative form, with source of complications to the patient.

#### *Indications for Perforating the Mastoid.*

Congestion of the mastoid bone so frequently accompanies otitis media, and the otitis media itself is so often only a secondary or concomitant manifestation of a mastoid infection, that we cannot be surprised to find affections of the mastoid requiring operative interference an occasional sequel to the most carefully and scientifically treated otitis. In fact, congestions of the mastoid cells and the bone itself have been regular post mortem findings in children suffering from otitis, where even no symptoms pointing to these conditions were recognizable during life. It will be well, therefore, to utilize these anatomical facts, and right here emphasize that a *rigorousness of the method*, as exerted by introduction of pressure to the touch, or even a greater degree of inflammation, a periaural swelling, a

evinced by edema over the mastoid occurring in the beginning of an otitis, is no *mastoiditis* and does not require an immediate opening of the mastoid. On the contrary, these congestive conditions often disappear, and heal out spontaneously. Mastoid congestion may be readily compared to the inflammation of the accessory nasal sinuses found during attacks of influenza and acute rhinitis, which also terminate favorably if left to themselves.

The pathological conditions affecting the mastoid that may interest us from the point of surgical interference are briefly stated as follows: Mastoid osteitis and periosteitis, empyema of mastoid antrum and cells, epidural and cerebral abscesses, various forms of meningitis, circumscript abscesses, sinus phlebitis and thrombosis. For the sake of completeness let me recall the formation of deep and cutaneous abscesses of the neck and head, lymphangitis and lymphadenitis, general pyæmia, septicæmia, etc. The bacteriological sources of infection which interest us mainly are the streptococci, pneumococci, and staphylococci. It is important to elicit the character of the bacterial infection, as the form of bacterial invasion may influence us in the selection of the time for operative interference, whether to operate a little earlier than even the general symptoms might otherwise demand.

A notable symptom pointing to the presence of pathological changes in the mastoid has been already referred to, namely, sensitiveness of the mastoid on pressure. While sensitiveness of the mastoid on pressure, in the beginning of an otitis must not be valued as a diagnostic sign for operative interference, and though even a persistency of the sensitiveness for a time may be overlooked, provided it had been present from the beginning of the otitis and shown a tendency to retrograde, persistency of the tenderness or a sensitiveness first manifesting itself in the course of the otitis, after drainage has been freely established—say, at the second or third week—is a cardinal symptom in the consideration of operative interference. A recurring sensitiveness, after the sensitiveness had already disappeared, is also an important indication. If besides the presence of tenderness we find a gradual reddening over the mastoid, standing off of the auricle, cessation of the discharge, followed by swelling over the mastoid, or the presence of an increasing otorrhœa which becomes gradually more and more purulent, presenting the character of bone pus, if we find gradually increasing and exacerbating temperatures our picture of a mastoid inflammation, requiring operation, is complete.

Certain points of selection on the mastoid are also to be looked for, and will aid us in establishing our indication, tenderness on pressure immediately over the fovea antri, on the apex, or on the lateral portion of the mastoid in the region of the sinus or emissary vein.

The otoscopic picture, the quantity and the character of the discharge, the appearance of the upper wall of the osseous portion of the external canal, are all important guides. At times the character and quantity of the discharge, with a bare rise of temperature, may be the only symptoms to point to a mastoiditis, without the presence of any noticeable changes about the mastoid. Temperatures must be carefully watched, for in some cases, when the

symptoms are more or less obscure, a sudden rise in temperature, or gradual rise, will enable us to diagnose the presence of mastoid involvement requiring an operation.

I have already exceeded the time allotted to me, and therefore cannot enter into the complete symptomatology of more serious and secondary complications: Let me only refer to the presence of vertigo, headache, neuralgia, convulsions, chills, septic temperatures, the quality and character of the pulse, the aid that may be obtained from the bacteriological and blood examination, the condition of the fundus, all symptoms which, if carefully noted, will enable us to operate on our cases in due time and also guide us to the extent to which our operations should be carried, whether a simple and thorough mastoid operation will suffice, or whether a more extensive operative interference will be indicated, such as exposure of an existing circumscript or a cerebral abscess, removal of infected thrombi in sinus thrombosis, the ligation of the jugular, and so on.

### Conclusions.

In conclusion I desire to enumerate briefly the following indications which have guided me in my operations, and which were formulated by me in 1896 in an article on the Indications for Perforating the Mastoid.<sup>1</sup>

I.—The mastoid should be opened in all cases of diagnosed osteitis, if under the usual antiphlogistic treatment the inflammation shows no tendency to resolution.

II.—In pronounced cases of otitis media, complicated by antral empyema, in which the discharge is purulent, and shows no tendency to evacuate through the middle ear.

III.—In all cases of prolonged otitis with profuse otorrhœa which show no tendency to resolve within a reasonable period, the time chosen for operation depending upon the manifest symptoms, whether, for instance, retention is present or the mastoid bone itself is involved.

IV.—In every case of acute otitis, in which there are dangerous symptoms of resorption, and in which the drainage cannot be established by paracentesis or by the natural perforation. In those cases, even without manifest symptoms of mastoid affection, the mastoid should be opened in order to produce more favorable drainage and enable a thorough cleansing of the ear.

V.—In all cases of mucopurulent otitis, in which the otitis is evidently maintained by the mastoid osteitis, the time for operation depending upon the condition of the patient and the presence or absence of symptoms pointing to retention or other complication of a serious nature.

VI.—In cases of protracted otitis, in which there are symptoms of serious secondary complications involving danger of extension of the inflammation inward toward the brain or to the sinus or downward, toward the neck.

VII.—In case of uncomplicated acute otitis, in which stenosis of the external canal prevents drainage and thorough cleansing of the middle ear.

# THE PRESENT STATUS OF THE ETIOLOGY OF SYPHILIS.

## *The Spirochæta Pallida; Its Biology and Ætiological Relation to the Disease.\**

BY RANDLE C. ROSENBERGER, M. D.,  
Philadelphia,

Assistant Professor of Bacteriology, Jefferson Medical College, and  
Director of the Clinical Laboratory, Philadelphia Hospital.

Previous to the discovery of the *Spirochæta pallida*, the lesions of syphilis were seemingly successfully produced in the lower animals by inoculation with human virus by quite a number of observers, among whom may be mentioned Metchnikoff and Roux, Martineau, Adrian, Hugel, Holzhauer, and Neisser (quoted by Flexner, *Journal of Experimental Medicine*, ix, No. 4, July, 1907).

That the disease could be transmitted was proved especially in monkeys, but far better in anthropoid apes. From the lesions produced there seemed to be no specific organism isolated. Numerous organisms and so called parasites were recognized, and especially amongst these apparently specific parasites was the *Cytorrhynchus luis* of Siegel (*Münchener medizinische Wochenschrift*, lii, pp. 1323, 1384, 1574, 1905), a so called protozoon which he described as occurring in the blood and tissues of syphilitics and in rabbits inoculated with the blood and other syphilitic products. This was followed by the work of Schaudinn and Hoffmann upon syphilis, with the result that they observed an organism constantly in the lesions of syphilis which they termed the *Spirochæta pallida*.

The constancy with which the *Spirochæta pallida* is found in primary and secondary lesions of syphilis seems to strengthen the assertion of Schaudinn and Hoffmann that it is the probable cause of the disease. The only remaining step seemingly necessary to complete this assertion is the cultivation of the organism upon some culture medium. It has been found in the lesions; it has produced lesions when inoculated into numerous animals (apes, monkeys, sheep, dogs, rabbits), and has been recovered from these lesions, and agglutination reactions have also been recorded by some few observers.

### *Morphology of Spirochæta Pallida.*

Schaudinn and Hoffmann (*Arbeiten aus dem kaiserlichen Gesundheitsamte*, xvii, No. 2, p. 527, 1905), and Berneise (*Deutsche Wochenschrift*, 1905, p. 22) first describe two forms of spirochæta occurring in syphilitic lesions, not only in superficial but also in deep lesions, and in the connected lymph glands.

The *Spirochæta pallida* is delicate, 4 to 10 mikra in length, average length 7 mikra, its breadth about 0.25 mikron. The spirals number 6 to 14, are abrupt, narrow, regular, and deep. It has pointed ends, progresses by rotating upon its long axis, and when at rest shows undulatory movements in its whole length, suggestive of the play of a vibratile membrane. It stains with difficulty, and with Giemsa's stain takes on a light purple hue. Schaudinn later called the organism the *Treponema pallidum*.

The *Spirochæta refringens*, the second form of spirochæta observed by Schaudinn and Hoffmann, differs from the other spirochæta in that it is more

ly wider and the spirals are further apart, it stains more intensely with the dye. The latter organism is found in other conditions than syphilis.

Vuillemin (*Comptes rendus de l'Académie des sciences*, cxl, No. 23, p. 1567, 1905) proposed the term *spironema* for spirochætae with sharp ends. The *Spirochæta pallida* would thus become the *Spironema pallidum*.

Some observers thought that the organisms *Spirochæta refringens* and *Spirochæta pallida* were simply stages of one organism, but this was before the demonstration of the parasite (*Spirochæta pallida*) in the blood. Among these may be mentioned Jesionek (*Münchener medizinische Wochenschrift*, 1905, No. 49, p. 2394), Kiolomenglon and von Cube (*Ibidem*, 1905, No. 27).

According to Pfender (*American Medicine*, March 10, 1907, p. 350), the generic name spirochæta Cohn, 1872, simply represents an amended spelling of spirochæta Ehrenberg, 1834. As the name spironema is preoccupied in zoology, the present correct name under the International Code should be *Treponema pallidum*. Stiles and Pfender (*American Medicine*, December 2, 1905) also proposed the term microspironema.

Minchin (*Lancet*, September 7, 1907, p. 707) mentions that the question of considering the spirochæta amongst the hæmoflagellates and not amongst bacteria is still being debated, but the weight of evidence was now toward the belief that they were really protozoa.

Mott (*Lancet*, September 7, 1907, p. 712) in exhibiting specimens of gummata of the brain, mentioned the fact that syphilis "is coming to be regarded as due to one form of protozoon, the *Spirochæta pallida*."

Schaudinn (*Deutsche medizinische Wochenschrift*, 1905, p. 1665), and Hexheimer and Löser (*Münchener medizinische Wochenschrift*, 1905, p. 2212), with Loeffler's flagella stain, have demonstrated flagella upon the *Spirochæta pallida*. The latter observers also succeeded with ordinary dyes.

Thesing (*Sitzungsberichte der Gesellschaft Naturforschender Freunde*, Nos. 8-9, 1905) disputes the propriety of classifying the spirochæta among the protozoa, and denies that the significance of *Spirochæta pallida* as the cause of syphilis has been proved.

Norris, Pappenheimer, and Flournoy (*Journal of Infantile Diseases*, May, 1906) assert that the absence of any definite indication of long division and absence of such chromatic particles as justify belief in the existence of micronucleus and macronucleus; the unquestionable occurrence of transverse fission; the positive evidence of production of active immunity, and, as shown by Novy, the formation of antibodies in sufficient amount to lend passive immunity, these facts indicate that the spirochæta must not be considered as protozoa. *California Journal of Experimental Medicine*, vol. vi, No. 8, p. 451) also believes in the transverse division of the parasite.

Schaudinn places *Spirochæta pallida* with the protozoa rather than with spirillar bacteria, allying it to the trypanosome group.

At Schaudinn's death the *Spirochæta pallida* was still considered as a bacterium, and the following

\*Read before the Pathological Society of Philadelphia at its meeting of December 14, 1907.

employed by Schaudinn, and cannot understand Schaudinn's grounds for placing spirochæta amongst animal parasites.

Schaudinn (*loc. cit.*) alleges that the parasite may possess, besides flagella, a vibratile membrane, though this is not yet clearly demonstrable. As these characters separate *Spirochæta pallida* not only from spirochæta and spirilla, but from all other related forms he adopted at one time the name *spironema* (of Vuillemin).

Hexheimer and Löser (*Münchener medizinische Wochenschrift*, 1905, No. 46, p. 2212) describe the presence of granules in the *Spirochæta pallida*, possibly of the nature of blepharoblasts, also small free bodies with nucleus, protoplasm, and membrane, possibly representing a developmental stage. They think the appearances formerly described as a vibratile membrane were artefacts, and confirm the presence of flagella.

Dalou (*Journal des maladies cutanées et de syphilis*, xvii, 481, 1905), with a quartz lens and magnification of from 2,500 to 4,000 diameters, states that an undulating membrane can be demonstrated.

Wechselmann and Loewenthal (*Medizinische Klinik*, Berlin, i, No. 26) report the appearance of a nucleus in quite a number of specimens examined with an ultramicroscope.

Doflein (Fourteenth International Congress of Hygiene and Demogogy, *British Medical Journal*, October 19, 1907, p. 1075) regards the spirochæta as taking a position midway between the bacteria and protozoa, and prefers to speak of them as proflagellates. They multiplied partly by transverse and partly by longitudinal division; the former method was best marked in the smaller forms; in some, what he regarded as multiple division could be seen, and no sexual processes had been noted.

Levaditi (*Ibid.*) asserts that many of the spirochæta had no distinguishable morphological characters.

Manson and Sambon (*Medical Record*, October 5, 1907, p. 586), in a table upon the hæmoprotozoa, classify three genera under spirochaudinidae (the individuals characterized by elongating and breaking up into numerous sporozoites), the leucocytozoon, spirochaudinina, and the treponema.

Krzyształowicz and Siedlecki (*Bulletin de l'Académie de science de Cracovie*, No. 9, pp. 713-728, November, 1905) assert that the body of the *Spirochæta pallida* is contractile and can become thereby much shorter and thicker, with its curves less sharp and at the same time more refringent; but the pointed extremities remain a distinctive feature. At some point, generally not far from the middle of the body, it is seen that for a short distance the body is straight, or nearly so, and very slightly thickened, and in this region a clear spot can be observed which is regarded as the nucleus. The ordinary method of reproduction is by fission in a longitudinal direction. The fission may for a time stop short of completeness, with the result that the two sister individuals may remain connected by their ends. In addition to the ordinary individuals they also describe forms which they consider as sexual individuals. These are thick, spindle shaped forms, with a head, which the authors consider try-

panosome like and propose to name *Trypanosoma luis*, although the minuteness of the organism makes it impossible to identify the undulating membrane; secondly, minute spirillum like forms with several nuclei. The former are regarded as macrogametes derived each by growth of single treponema individuals; the latter as microgametes formed by a process akin to sporulation from an individual with multiple nuclei. Conjugation between the two forms was noticed in a single case in "materials taken from a very large primary ulceration which was beginning to cicatrize spontaneously."

Kreibich (*Wiener klinische Wochenschrift*, No. 21, 1907), in staining flagella of bacteria with silver solutions, noticed attached flagella which were often spiral and twisted together like braid, and being pointed at both ends reminded him very much in appearance of the *Spirochæta pallida*. He then questions whether on account of this similarity the *Spirochæta pallida* may not be a protozoan flagellum instead of a difficultly stained individual bacterium, especially because in the spirochæta distinction between nucleus and membrane has not been established. Kreibich answers his own question by saying that the *Spirochæta pallida* is unlikely to be identical with a flagellum, because no protozoan body from which the latter might have come has yet been discovered.

#### *Occurrence of the Spirochæta Pallida in the Lesions of Syphilis.*

Mulzer (*Berliner klinische Wochenschrift*, September 4, 1905) states that the *Spirochæta pallida* is almost always found in the products of infectious syphilis, and has never been observed in the healthy or in nonsyphilitic persons.

Levaditi and Petresco (*La Presse médicale*, September 30, 1907) blistered three syphilitic women and found the parasite in each case.

Levaditi and Salmon (*La Semaine médicale*, November 29, 1905, No. 48) found the organism generally distributed through all the organs, as lungs, adrenals, liver, skin, etc. (indicating an acute spirillosis), in a stillborn child. The disposition of the *Spirochæta pallida* in groups around the vessels in the liver seems to favor the penetration of the microorganism by the vascular route.

Scholtz (*Deutsche medizinische Wochenschrift*, September 14, 1905) found the *Spirochæta pallida* in four cases of syphilis comprising condyloma acuminata.

Burnet and Vincent (*La Semaine médicale*, November 29, 1905, No. 48), in recent syphilitic chancre (four or five days), found the organism abundant in the papillary layer of the adjacent skin, but rarely in the central part. They were also successful in demonstrating the parasite in the hypertrophied conjunctival layer and in the lymph spaces.

Levaditi and Manouelian (*Ibid.*) state that, in a study of a number of chancres and syphilitic papules, in all they were able to find the *Spirochæta pallida* in the tissues and bloodvessels and endothelial cells, undoubtedly playing a part in the production of periarthritis and the characteristic lesion or chancre.

Veillon and Girard (*Ibid.*, No. 52, December 27, 1905) assert that the roseola is not a toxic lesion,

but is caused by a true embolism of the parasite, which, transported by the blood, becomes fixed in the terminal capillaries, where it provokes an intense congestion.

Tchlenoff (*Roussky Vrach*, June 18, 1905) studied fourteen cases of syphilis, in which he was able to demonstrate the *Spirochæta pallida* in all instances of the secretion of chancres and inguinal glands. In all cases of hard chancres he found spirochætæ in the specimens and also in the moist papules, as well as a papule upon the tongue.

Soberheim (*Münchener medizinische Wochenschrift*, lii, No. 39) observed the *Spirochæta pallida* in fifty out of fifty-eight cases of certain syphilis, the positive cases being those with primary or secondary lesions, while the eight negative cases were tertiary. In thirty-four control cases of various affections the findings were invariably negative.

Schlumpert (*Deutsche medizinische Wochenschrift*, 1906, No. 36, p. 1452) found the *Spirochæta pallida* in the conjunctiva, sclerotic, cornea, iris, choroid, and in the muscles of the eye and lachrymal sac. It was most frequently seen within the vessels and free in the blood.

Schütz (*Münchener medizinische Wochenschrift*, liii, No. 12), in making comparative studies of Schaudinn's *Spirochæta pallida* and Siegel's *Cytorrhycles luis*, mentions the fact that both are always found together and close to or inside the red corpuscles. He thinks it is possible that they represent merely different phases in the life cycle of a single microorganism.

Schor (*Roussky Vrach*, September 10, 1905) examined twenty-five adults and seven children for the spirochætæ of syphilis. In twenty-five women with condyloma the organism was demonstrable in fifteen; in two chancres only one showed the parasite, and in three roseolous eruptions none showed a positive result. In thirteen out of fourteen cases of papular syphilide it was found; five cases of dry papules were negative. No organisms were found in the placenta of five women with condyloma, and in four infants no organisms were found in any of the organs.

Ravant and Ponselli (*Gazette des hôpitaux*, July 13, 1906) found the parasite in the blood of a child aged two months suffering from severe congenital syphilis. The blood was taken two hours before death.

Gierke (*loc. cit.*) reports positive findings in eleven cases of congenital syphilis. He obtained positive findings in tissues that had been preserved for years, especially those kept in formol. His findings also prove that the treponema long resists the effects of maceration.

Nattan-Lanier and Bergeron (*La Presse médicale*, January 10, 1906) report three cases of syphilis in which the *Spirochæta pallida* was found in the blood.

Baudi d'Agrè (*Atti degli ospedali e delle cliniche*, xvi, No. 51, 1906) calls attention to the importance of the accumulations of spirochætæ in the cells. According to him it is not a phagocytic process, as the organisms seem to be intact, while the cell seems to have suffered. He believes that the condition indicates actual vital parasitism of the cell.

MacLennan (*British Medical Journal*, May 12, 1906) was able to demonstrate *Spirochæta pallida* in only eight out of forty cases of syphilis in the female, but found the *Cytorrhycles luis* in every case.

Sydney Stephenson (*Ophthalmoscope*, March, 1906) states that he found the *Spirochæta pallida* in the corneal lesions in two cases of keratomalacia in syphilitic infants.

Mohn (*Zeitschrift für Geburtshilfe und Gynäkologie*, lix, No. 2) found the pale spirochætæ in more than 5 per cent. of umbilical cords examined, and in almost 70 per cent. of the placentæ. The absence of nerves in the placenta shows that the organisms found cannot be explained away as "silver stained nerve fibrils," as some have asserted in respect to other tissues. The fact that the placenta and membranes are free from external infection also excludes error from this source. They were never found in the decidua or intervillous spaces, but they swarmed in the foetal villi and in the umbilical cord when the foetus exhibited signs of syphilis—not otherwise. He further maintains that the parasites find their way into the ovum from the mother or in the spermatic fluid, or pass from the mother to the foetus later. They proliferate in the foetus, acquiring new virulence, and pass thence into the placental circulation.

Jacquet and Sevin (*Annales de dermatologie et de syphiligraphie*, June, 1905) found the *Spirochæta pallida* in secondary lesions, but failed in twenty-three tertiary lesions.

Kraus and Prantschoff (*Wiener klinische Wochenschrift*, 1905, No. 37, p. 941) found the *Spirochæta pallida* in thirty-two out of thirty-seven hard chancres; and in eighteen out of twenty-five papules. In the lesion of four macaque monkeys *Spirochæta pallida* were found.

Mulzer (*loc. cit.*) was successful in observing the parasite in twenty out of twenty-two cases; in one instance he found a mass of organisms of from twenty to forty individuals. He was unable to find roseolar blood and syphilis hæmorrhagica neonatorum.

Scholtz (*Deutsche medizinische Wochenschrift*, September, 1905, No. 37) doubts whether the *Spirochæta pallida* is of ætiological significance. In primary and secondary lesions he had nineteen positive and eleven negative results and two positive and one negative result in congenital syphilis.

Kille and Voekerdt (*Münchener medizinische Wochenschrift*, 1905, No. 34) found *Spirochæta pallida* in twenty-two different lesions in fourteen syphilitics. They obtained negative results in roseolar blood and syphilis hæmorrhagica neonatorum.

Sobernheim and Tomaszewski (*Ibid.*, 1905, No. 39, p. 1857) were successful in fifty primary and secondary syphilitics in demonstrating the *Spirochæta pallida*, but were unsuccessful in eight cases showing tertiary lesions.

In tertiary lesions Schaudinn (*Deutsche medizinische Wochenschrift*, October 10, 1905) observed the organism as a granular resting form. He also cites seventy cases of syphilis in which the organism was constantly found.

Siebert (*Ibid.*, 1905, No. 41) obtained positive results

sults in fifty-two out of sixty-six cases of primary, secondary, and congenital syphilis; negative in lesions not syphilitic, and in seven tertiary lesions.

Roscher (*Berliner klinische Wochenschrift*, 1905, Nos. 44, 45, 46), of 206 syphilitic lesions, obtained 184 positive and twenty-two negative results.

Zaboltny (*Roussky Vrach*, March 17, 1907) obtained fluid (by means of an aspirator from indurated chancres) which was rich in *Spirochæta pallida*. The addition of physiological salt solution retains the organism in viability for several days. The presence of serum of those suffering from syphilis, when brought in contact with these organisms, causes agglutination, which phenomenon is complete within three or four hours. This fact, the author thinks, speaks more for the specificity of the *Spirochæta pallida*.

Pasini (*Giornale italiano delle malattie veneree e della pelle*, 1906, No. 5, p. 4), in a child two and a half years old suffering from hereditary syphilis, presented two resumptions of the disease. The first was characterized by exanthematous papules, and the second time by an eruption of papules and a mucous patch on the palate. The child was treated by sublimated baths, by inunctions, and by injections. It died in two and a half years of tuberculosis of the lungs and did not present any acute lesions of syphilis after recovery of the second recurrence. On the left leg there was an atrophic lesion resulting from the first infection, and this was examined histologically by Bartanelli and Levaditi. Pasini found in this lesion numerous *Spirochæta pallida*, some intracellular, but for the most part extracellular, some perfectly preserved, others in a degenerating condition. He concludes that, in the treatment of this child, though apparent health had been restored, the *Spirochæta pallida* preserved itself during the long period of latency in the same tissues.

The same observer in a later article (*Ibid.*, 1906, No. 5, p. 5) asserts that the penetration of the epithelial cells by the *Spirochæta pallida* is not an agonizing phenomenon, but is followed by the phenomena of degeneration, and that the organism could well survive in the urine, saliva, and in the perspiration of children with hereditary syphilis, and in the sperm of an adult.

Wersilowa (*Centralblatt für Bakteriologie*, xlii, pp. 513 to 518, October, 1906) alleges that the transmission of syphilis to the child could be effected by the ovum and spermatozoa, sometimes by the placenta. He cites the history of three congenital syphilis: The first one was macerated, the second lived only several hours, and the third died one hour after birth. The mother was apparently healthy. The first two presented plantar pemphigus and numerous papules and the third did not present any cutaneous manifestations. Examination of spreads from the umbilical cord, heart, lungs, pemphigus, and papules revealed *Spirochæta pallida*, while sections showed numerous organisms in the placenta, umbilical cord, liver, heart, lungs, spleen, pemphigus, and papules. The author has made similar studies in twenty-five other cases of hereditary syphilis, but did not confirm the preceding declarations. Of all these examinations he concludes that the parasite of syphilis could be transmitted to the mother by the placenta or umbilical cord, and that he could

verify the spirochæta in the placenta and cord and the organs of the children without the mother presenting the least symptom of the malady.

Mühlens and Max Hartmann (*Ibid.*, xliii, January 17, 1907) state that the *Cytorrhynchus luis* of Siegel is not a protozoon and that similar bodies exist in the normal blood, and that these forms are to be considered as the products of disintegration of cells, especially the red blood cells.

Mühlens (*Ibid.*, xliii, March 23, 1907; April 6, 1907) confirms the relation of *Spirochæta pallida* as the ætiological factor of syphilis. In twenty-two cases of primary lesions and in buboes he found it in a number of cases. In eighteen syphilitic foetuses he found the organism constantly, even though the foetus was macerated. He also emphasizes the fact that the spirals obtained by Levaditi's method are true spirochætæ. He concludes by citing the case of a syphilitic infant that died four hours after birth and was examined one hour after death. Examination of spreads of different organs, liver, adrenal, and lung, showed great numbers of motile spirochætæ, fifty to a microscopic field, in the smear from the adrenal.

Ribadeau-Dumas et Poisot (*Comptes rendus de la Société de biologie*, lxii, February 16, 1907), in an infant presenting diffuse hepatitis with hæmorrhages and diffuse miliary gummata, showed uniform presence of *Spirochæta pallida*. In the other parenchymatous organs the parasites were found to be in such numbers as to constitute emboli.

Bab (*Zeitschrift für Geburtshilfe und Gynäkologie*, lix) in fourteen instances of congenital syphilis claims that the biological and bacteriological investigations gave exactly the same result. Not only those organs that were free from spirochætæ gave extracts free from autogens, and organs containing the parasites gave extracts containing autogens, but also a great number of spirochætæ corresponded to a great number of antigens. The contrary was also true, that a small number of spirochætæ contained a small number of antigens.

The important problem presents itself, that the placenta acts like a sponge and stores up the dissolved syphilitic toxines, and the granulation tissue elements act as phagocytes, which also absorb the dissolved toxines and by this process endeavor to make them inert. But it is possible that after a time the barrier becomes incompetent toward the mother or toward the child and becomes permeable to the toxines. The placenta seems to correspond to the foetal liver and spleen, which are sometimes swollen but contain no spirochætæ.

He examined sixty-four cases of syphilis and found the spirochæta most commonly situated in the vessel wall and in connective tissue. He was able to detect them in the spleen in 62.9 per cent. and in the thymus gland 55.6 per cent. In the foetal ovary the interstitial tissue is especially affected and one illustration accompanying his article shows a spirochæta in the ovum itself. This penetration into this structure proves distinctly that it cannot be nerve or other tissue fibres. In thirty-nine cases examined, he found the placenta free from spirochætæ in thirty-seven. In general the presence of the parasite seems to end at the navel, while in 50 per cent. the arterial walls and in 55.6 per cent. the venous walls of the

umbilical cord of his positive cases contained the organism. He also seems to think that one cannot avoid being impressed with the fact that the spirochætal masses are disseminated through the body into different organs in the same manner as an embolus is carried by the blood. He then mentions the case of a congenitally syphilitic infant from a woman who had intercourse with a syphilitic at the fourth month after conception, though herself healthy. The thymus gland, kidneys, uterus, meninges, and eyes contained spirochætae.

Buschke and W. Fischer (*Deutsche medizinische Wochenschrift*, 1906, xxxii, p. 752), Levaditi and Manouelien (*Comptes rendus de la Société de biologie*, 1906), Reischauer (*Deutsche medizinische Wochenschrift*, xxxiv, August 24, 1905), Oppenheim and Sachs (*Ibid.*, 1905, Nos. 29 and 31; and *Münchener medizinische Wochenschrift*, 1905, pp. 1507 and 1517), were also successful in obtaining positive results in the majority of cases studied. The last observers found *Spirochæta pallida* in thirty-nine hard chancres and papules, and failed in twenty-one. They were unsuccessful in the examination of nine buboes, twenty-one examinations of the blood, fifteen roseolar spots, two mucous plaques, seven gummata, and four cases of congenital syphilis. In forty-two nonsyphilitic conditions they found no *Spirochæta pallida*.

Bertarelli and Volpino (*Centralblatt für Bakteriologie*, November 24, 1905) found *Spirochæta pallida* in twenty-six cases out of forty-two primary and secondary cases. By the use of Levaditi's method they demonstrated great numbers of the organisms in sections of the liver in a congenitally syphilitic child, and control observations showed that they had not to deal with elastic fibres, connective tissue fibrils or nerve endings.

Rosenberger, in fifty-six cases of primary and secondary syphilis, as well as the viscera of congenitally syphilitic infants, found the *Spirochæta pallida* constantly. They were, as a rule, few in number in spreads, though in one chancre as many as forty or fifty organisms could be seen. They rapidly decreased in number when mercury was administered to the patient.

Chele and McKimie (*Journal of the American Medical Association*, February 16, 1907) report upon twenty-four cases of acquired syphilis in which positive findings were reported in fourteen and negative in ten. In the patients giving a negative result seven had received antisyphilitic treatment, the other three had not. They examined thirty-four pieces of tissue in all, including seven chancres, nineteen cutaneous secondary lesions, apparently healthy skin from syphilitics, four tuberculous syphilides, and one gumma of the brain.

Richards and Hunt (*Lancet*, September 30, 1907) found the *Spirochæta pallida* in three cases in the blood taken from the roseolar rash on each of ten successive days.

Dudgeon (*Ibid.*, March 10, 1906) observed the *Spirochæta pallida* in six cases of primary syphilis, two cases of secondary syphilis, one case of tertiary syphilis, and three cases of congenital syphilis.

Sherman (*Ibid.*, March 17, 1906) presented his personal research with an excellent bibliography on the subject. He records five hard chancres with positive

results; in two the results were doubtful, and three negative. Two nonulcerated papules gave positive results, two dry papulosquamous syphilides gave negative results, and two roseolar rashes were also negative. Of four condylomas examined, three were negative and one doubtful. Negative results were also obtained in four glands and one rupioid syphilide. He concludes that the *Spirochæta pallida* is found only in hard chancres and in closed papules; in other words, in typical syphilitic lesions.

Flexner (*loc. cit.*) gives the results of several cases of acquired syphilis and also of congenital syphilis in which he obtained positive and constant results in all cases. In the case of films made from lesions he was able to demonstrate the parasite several months afterward. Fragments of lung tissue kept in the refrigerator (2° to 4.5° C.) for one month showed very little if any change in the form and staining of *Spirochæta pallida*, while after three months no pallida could be stained. The slow autolysis without putrefaction shows the resistance displayed by the organism against the autolytic ferments.

Grouven and Fabry (*Deutsche medizinische Wochenschrift*, xxxi, No. 37) observed the *Spirochæta pallida* in fifteen out of twenty-one cases.

Kraus and Prantscoff (*Wiener klinische Wochenschrift*, xviii, No. 22) found the parasite in fifty out of sixty-two examinations of syphilides.

Schultz (*Journal of Medical Research*, xv, p. 363, 1906), reporting upon the distribution of the *Spirochæta pallida* in two cases of congenital syphilis, says that it is to a marked degree an intracellular parasite and that multiplication of the organism occurs chiefly in the perivascular lymphatics and within the tissues themselves; not within the larger bloodvessels.

Wiens (*Archiv für Schiffs- und Tropenhygiene*, x, No. 15, pp. 459-63, 1906) reports six cases of syphilis in Chinese in which he was able to demonstrate the *Spirochæta pallida*. In four cases he obtained it from chancres, in one from serum of a roseolous eruption, and in one case from juice from an inguinal gland.

Bab (*Deutsche medizinische Wochenschrift*, November 29, 1906, pp. 1945 to 1948) records finding the parasite in the different structures of the eye, except the crystalline lens, in a syphilitic fœtus. He thinks that the distribution of the organism in the different parts of the eye is in accord with the frequency of choroiditis, iritis, and parenchymatous keratitis in hereditary syphilis. The same observer in a later article (*Münchener medizinische Wochenschrift*, November 12, 1907, No. 46) was able to demonstrate the *Spirochæta pallida* in the liver, spleen, testicles, and costochondral articulations in a congenitally syphilitic child born of an apparently healthy mother.

Blaschko (*Berliner klinische Wochenschrift*, No. 12, 1907), in descriptive diagrams, showed by the method of Levaditi, found the *Spirochæta pallida* in all cases but observed the organisms most abundant at the periphery of the lesion.

Almeida and Doyal found the same organism in cases of hereditary syphilis caused by the presence of the *Spirochæta pallida* in the blood and all tissues, accompanied by extensive nodules in the

liver the congestion attains an extreme degree, recalling the characters of the "asystolic liver."

Reuter (*Zeitschrift für Hygiene und Infektionskrankheiten*, 1906, No. 49) found typical examples of *Spirochæta pallida* in the tunica intima of the aorta in a case of aortitis (Döhle and Heller's variety of aortitis) and also mentions finding the organism in a gumma of the lung, and in interstitial pancreatitis of a congenital syphilitic.

Nöggerath and Stahelin (*Münchener medizinische Wochenschrift*, August 1, 1905) allege to have observed the *Spirochæta pallida* in the blood obtained from the lobe of the ear in three cases of undoubted secondary syphilis.

Risso and Cipollino (*Riforma medica*, August 26, 1905) in ten cases of syphilis were successful in demonstrating the *Spirochæta pallida* in five out of seven cases in the gland, juice; also in several mucous patches and one condyloma. They failed, however, to find the organism in two chancres, ulcerated gummata, and in a closed gumma of the forehead.

#### Technique.

In spreads from chancres, papules, and other syphilitic lesions Schaudinn and Hoffmann originally recommended Giemsa's azure blue eosin stain, but very good results have been obtained with Wright's, Jenner's, Romanowsky's, Leishman's, and Goldhorn's stains. Many observers recommend various aniline dyes, a filtered saturated aqueous solution of gentian violet (Fox), and other modifications of the various blood stains.

Among those who recommend the anilin dyes may be mentioned Davidsohn (*Berliner klinische Wochenschrift*, xlii, No. 31); Rille and Vockerodt (*Münchener medizinische Wochenschrift*, lii, No. 34, pp. 1620-23); Ploeger (*Ibid.*, lii, No. 29); Hexheimer (*Ibid.*, 1905, No. 39); Oppenheim and Sachs (*Deutsche medizinische Wochenschrift*, xxxi, July 20); Bandi and Simonelli (*Gazzetta degli ospedali e delle cliniche*, 1905, Nos. 85 and 105); Moncorvo (*La Presse médicale*, 1905, 104-840); Dudgeon (*Lancet*, August 19, 1905, p. 522), and Weitlauer (*Münchener medizinische Wochenschrift*, 1905, No. 47, p. 2293).

In sections of tissue from syphilitics, it seems that the best results are obtained by impregnating with silver nitrate in strengths of from 1 to 3 per cent. The first investigators to use this method were Bertarelli and Volpino (*Centralblatt für Bakteriologie O.*, November 24, 1905). Since these observers used the method numerous others have obtained very good results, among whom may be mentioned Buschke and Fischer (*Berliner klinische Wochenschrift*, 1906, Nos. 1, 6), Gierke (*Münchener medizinische Wochenschrift*, liii, No. 9, 1906), and Levaditi (*Annales de l'Institut Pasteur*, No. 1, p. 43, January, 1906). The latter's technique, together with one which he and Manouelian (*Comptes rendus de la Société de biologie*, lx, No. 3, 1906) originated, are by far the best for the demonstration of the *Spirochæta pallida* in the tissues. The first technique is as follows:

The tissue is cut in small masses and fixed for twenty-four hours in a 10 per cent. solution of formaldehyde; then placed in alcohol for the same time. They are then washed in water for a short period,

after which they are put in a bath of 1.5 to 3 per cent. freshly made solution of silver nitrate for three days, changing the solution daily, maintaining the body temperature and excluding the light. The tissue is then placed in a reducing bath which consists of a 2 per cent. solution of pyrogalllic acid, with the addition of 5 per cent. formaldehyde. After twenty-four hours they are dehydrated, cleared in xylol, and embedded in paraffin.

The method recommended by Levaditi and Manouelian differs from the plain Levaditi method in that, just before impregnation with the silver they add 10 per cent. pyridine to this solution, and for the reducing bath a mixture of pyrogalllic acid, acetone, and pyridine. In the silver solution the tissues are kept four to six hours at 50° C., or at room temperature two to three hours in glass stoppered bottles.

Flexner (*loc. cit.*) prefers and obtains the best results in films by the use of the direct silver staining, recommending the technique of Stern (*Berliner klinische Wochenschrift*, lxiv, p. 400, 1907), which is as follows:

The exudation is placed in the incubator at 37° C. for one hour, then in a 10 per cent. solution of silver nitrate for one hour in diffuse daylight. A colorless glass vessel should be used. The preparation gradually takes on a brown color and when it has acquired a metallic sheen it is removed from the silver nitrate solution and washed in water. In such a preparation the form of the blood corpuscles is retained; they give a strong, dark contour and show fine granules. There is but little precipitate and it causes no annoyance in looking for the organism. The *Spirochæta pallida* appear deep black to bright brown against an almost colorless background. A reduction of the preparation is neither necessary nor advisable. Placing it in the sunlight gives the material a brown color, which becomes gray black from a quarter to half an hour later, and finally entirely black. The *Spirochæta pallida* appear almost colorless against a dark background.

Schmorl (*Deutsche medizinische Wochenschrift*, xxxiii, p. 876, 1907) fixes in 4 per cent. formaldehyde, cuts frozen sections, and places in formaldehyde or distilled water and stains with Giemsa's stain (one drop of stain to one c.c. of distilled water). Great precaution must be observed as to cleanliness of vessels used. After one hour place in a fresh staining solution and let it remain from twelve to twenty-four hours. When sufficiently stained, the section should be a deep red to violet blue. It is now placed in distilled water or in a concentrated solution of potassium alum until it becomes a bright blue. It requires but a short time in the potassium alum solution to distinguish the section. It should then be washed in water for a short period; too long washing is not good for the preparation. It is then mounted in glycerin jelly, cedar oil, or neutral Canada balsam.

Ravant and Ponselli (*loc. cit.*) take 30 c. c. of water and 30 drops of blood added drop by drop. The hæmoglobin becomes diffused through the water, and after three hours a fibrinous clot forms. The clot is withdrawn, washed several times to free it from water, cut into sections, and stained by Levaditi's method.

Levy-Bing (*Bulletin médical*, xix, No. 49) stains with an alcoholic (methyl) solution of azul blue and counterstains with eosin. The *Spirochæta pallida* is stained an orange rose color.

Reitman (*Deutsche medizinische Wochenschrift*, xxxi, p. 997) first fixes the spread in absolute alcohol, washes in water, places in a bath of phosphomolybdic acid, again washes in water, stains with carbol fuchsin, washes in water, then 70 per cent. alcohol, and alternates with water until no more color comes away. The spirochæta is stained a deep red.

Follet (*Comptes rendus de la Société de biologie*, lxii, p. 667, April 20, 1907) recommends collecting the saliva some time before a meal and staining with a mixture of glycerin, acid fuchsin, and carbolic acid, for the demonstration of spiral organisms. Another method, using a mixture of glycerin, methylen blue, and carbolic acid, he says has permitted him to observe from 00 to 300 spirals, "certainly not all the *Spirochæta pallida*." A third formula consisting of chloroform, methylen blue, acid fuchsin, and carbolic acid, is more rapid and gives less precipitate and presents the classic coloration of the *Spirochæta pallida*.

Proca and Vasilescu (*Ibid.*, lviii, p. 1044, 1905) recommend to fix the preparations in absolute alcohol for thirty minutes; then place in a bath composed of carbolic acid 50 c.c., tannin 40 grammes, water 100 c.c., fuchsin (2 to 5 per cent. alcoholic solution) 100 c.c. for ten minutes. Wash in water, and stain for ten minutes with carbol gentian violet.

Volpino (*Rendiconto delle sessioni dell' Accademia medica di Torino*, July 14, 1905) allows sections to remain in a solution composed of silver nitrate 0.5 grammes in 100 c.c. of distilled water for twenty-four to forty-eight hours. They are then washed in water, then transferred to a solution of tannin 3 grammes, gallic acid 5 grammes, sodium acetate 10 grammes, distilled water 350 c.c. Allow them to remain for fifteen minutes, until they are brownish in color; wash in water, dehydrate, clear, and mount in balsam.

Bab (*Zeitschrift für Geburtshilfe und Gynäkologie*, lx, No. 2, 1907) thinks that the organism possesses an affinity for mercury equal to that for silver, and recommends trying mercury phenylate.

Nöggerath and staehlin (*loc. cit.*) take one c.c. of blood from a vein, mix with 10 c.c. of 1 per cent. acetic acid in water, centrifugize, and examine the deposit in the ordinary way.

McNeal (*Journal of the American Medical Association*, February 16, 1907) recommends a mixture of methylene violet, methylene blue, yellowish eosin, and pure methyl alcohol. The stain is allowed to remain upon the smear for forty-five to sixty seconds, then immersed in about 10 c.c. of a 1 in 20,000 solution of sodium carbonate and the mixture stirred by tilting the dish. After one or two minutes' immersion the cover glass is removed, washed in distilled water, cleaned, and dried upon blotting paper and mounted in water and examined with a 1000x objective.

Schereschewsky (*Deutsche medizinische Wochenschrift*, March 21, 1907, p. 492) fixes one minute in osmic acid vapor, passes the cover slip three times in flame, then places in a mixture of 1 part Gram's

solution to 8 to 10 parts water. The preparation is heated in a Petri dish upon a water bath for ten to fourteen minutes, and when the cover slip presents a scum of a reddish color the procedure is at an end. It is said that by this method the preparations are so clear that the organisms can be observed with a dry objective.

Benda (*Berliner klinische Wochenschrift*, April 15, 1907, pp. 428-432; April 22, 1907, pp. 480-484) by studying the *Spirochæta pallida* by the silver process of Levaditi, asserts that the parasites are the same organisms that are found in spreads from organs, and not fragments of tissue elements.

Zabel (*Medizinische Klinik*, May 19, 1907, pp. 580-582), in staining sections of organs, fixes in formaldehyde and stains with silver nitrate. The organisms appear larger than those made from fresh preparations stained with anilin dyes.

Mandelbaum (*Münchener medizinische Wochenschrift*, November 12, 1907) recommends staining the *Spirochæta pallida* in the fresh state by mixing the scrapings from a chancre or papule with Loeffler's methylen blue, and examining in the hanging drop with a 1/12 inch oil immersion lens. By this method the spirochæta stains pale blue, while other spiral organs like *Spirochæta refringens* stain very heavily. By this method the granules described by Hexheimer are distinctly brought out. Mobility can be observed for twenty-four hours, though the cover glass preparation can be kept for weeks by sealing with paraffin.

Sabolotni and Maslakovitz (*Rousski Vrach*, No. 11, 1907) observed the *Spirochæta pallida* in the serum (obtained by Biers apparatus applied over the syphilitic lesions) become attached to one another at the ends, form star like masses, and eventually undergo granular degeneration.

#### Inoculation Experiments Upon Animals.

Metchnikoff (*Berliner klinische Wochenschrift*, May 22, 1905) found the *Spirochæta pallida* in the glands and chancres of his inoculated apes (twenty-three out of thirty-one experimental lesions), and Arnol and Salmon (*Annales de l'Institut Pasteur*, July 25, 1904) report upon the features of the lesions produced upon chimpanzees, a male and a female, both showing chancres which were identical histologically with those in man.

Piorkouski (*Berliner klinische Wochenschrift*, December 19, 1904) injected 5 to 10 c.c. of blood from a patient under active mercurial treatment into a horse, intravenously or subcutaneously. Four weeks later a maculopapular rash appeared, which, examined by various experts, was pronounced to be syphilitic in nature. (No mention of *Spirochæta pallida*.)

Neisser (*Deutsche medizinische Wochenschrift*, xxxii, No. 13) has succeeded in inoculating monkeys with tertiary lesions, provided the lesion is not destroyed by suppuration or necrosis. He was also successful in producing positive inoculations by using the nasal secretion, blood and tissues from various organs, from children with inherited syphilis. He asserts the bodies of children with inherited syphilis are swarming with parasites which can pass by way of the blood into the organs.

Hoffmann (*ibid.*) also reports experiments with monkeys which have confirmed the characteristic nature of the blood during the early stage of syphilis.

Metchnikoff and Roux (*Bulletin de l'Académie de médecine*, May 18, 1906) report upon the circulation of syphilitic material into apes and man, followed by the application of a strong mercurial ointment applied locally. They found that if this application was made within one to eighteen hours it destroyed the syphilitic virus, but if made later than this syphilis developed.

Neisser (*Bulletin de la Société française de prophylaxie sanitaire et morale*, Nos. 4 and 5, April and May, 1906) proceeded upon these lines, but without success. On the contrary, though the mercurial ointment was applied one hour after the inoculation, the chancre developed in due course. He came to the following conclusions: That the chancre developed in the same manner in a mercurialized subject as in one not under that treatment, and that the disease became generalized in exactly the same manner among animals which had been mercurialized and those which had not.

Metchnikoff (*British Medical Journal*, October 19, 1907, p. 1075) at a later date experimented upon the prophylaxis of syphilis, using instead of mercury, atoxyl. This material was found to protect the monkeys from the infection, even after a single dose. It was further found that the injection of atoxyl could be successfully carried out a week or even a fortnight after the inoculation. That the atoxyl had really neutralized the virus was shown by the fact that the monkeys could be reinfected with syphilis some months after the atoxyl treatment. He then spoke of giving atoxyl by the mouth, and concluded by saying that these preventive measures had been applied to man without any harmful after effects.

Yancke (*Medizinische Klinik*, April 28, 1907, pp. 486-7) took fragments of placenta, liver, kidney, spleen, and testicle from a syphilitic fetus of six months, macerated these in distilled water and filtered under pressure through a Chamberlin filter. The filtrate was inoculated into the superciliary region of a monkey, and was followed by a slight infiltration which reached its height in seven days. Forty-two days after inoculation he found a lesion similar to those noticed in primary syphilis. The long period of incubation was probably due to the small number of organisms contained in the filtrate. He attributed the result of this experiment to two factors: First, to the emulsion, and secondly, to the high pressure of  $2\frac{1}{2}$  atmospheres.

Thibierge, Ravant, and Burnet (*La Semaine médicale*, No. 7, p. 80, February 14, 1906) experimented upon macaque monkeys with fragments of enlarged glands, of papules, and chancres; inoculated them with a series of other animals, and found the *Treponema pallidum* in the secretions and sections of tissue. They conclude that the experiment in passage, from the man to the animal, of the parasite speaks in favor of the organism being the pathogenic microbe.

Simonelli and Bandi (*Gazzetta degli ospedali e delle cliniche*, January 7, 1906) inoculated a female ape with material from a syphilitic perianal hypertrophic papule. In due time a chancre developed, but the authors were unable to demonstrate the *Spirochæta pallida* in the lesions. They found certain

masses of very delicate threadlike structures, some of which were straight, and others wavy.

Metschnikoff and Roux (*Annales de l'Institut Pasteur*, November, 1904, p. 761, and *Bulletin de l'Académie de médecine*, 1905, p. 468) succeeded in infecting monkeys with syphilis, and in four out of six cases found *Spirochæta pallida* unaccompanied by other forms.

Hoffmann and Walter Bruning (*Deutsche medizinische Wochenschrift*, April 4, 1907, pp. 553-4) succeeded in inoculating a rabbit and then to inoculate the virus to monkeys. Two dogs were inoculated with the fragments of a chancre, which was followed in sixteen and twenty-one days by keratitis of a specific character, with the presence of *Spirochæta pallida*, and clinically possessing the characters described in the monkey. By scarifying the cornea they proved that laying bare of the bloodvessels is not absolutely necessary.

Bertarelli (*Centralblatt für Bakteriologie*, April 25, 1907, pp. 790 to 793) has successfully inoculated a sheep and a dog with virus that passed seven times through rabbits by inoculations into the cornea. The cornea of the dog was scarified and smeared with the virus from a cornea of a rabbit, and sixteen days later a keratitis, specific in character, was noticed. In the dog the lesion was more extensive than in the sheep. The syphilitic nature of the lesions was confirmed by microscopical examination, and only two gave positive results, and the organisms have also been few in these two cases.

Hoffmann (*Berliner klinische Wochenschrift*, xlv) is said to have successfully inoculated four monkeys (two *Macacus rhesus* and two cercopithecus) with syphilitic blood.

Finger and Laudsteiner (quoted by Flexner, *Medical News*, December 9, 1905) report a successful transmission of syphilis to the monkey by means of inoculation of a large amount of gummatous material.

Kraus and Prantschoff (*loc. cit.*) inoculated monkeys, *Macacus rhesus*, with syphilitic material, and found that the initial lesion produced contained numerous *Spirochæta pallida*, being identical morphologically and tinctorially with the organism found in man. They were also successful in inoculating from one ape to another.

E. Finger and Laudsteiner (*Sitzungsberichte der Kaiserlichen Akademie der Wissenschaften in Wien*, cxv, No. 3, April, 1906, pp. 179 to 199) inoculated six monkeys with the blood obtained from syphilitics in full eruptive period, and not one inoculation was followed by a positive result. These data seem to show that the blood collects in the cells in the course of the secondary eruption and is not constantly virulent, and accords with the histological examination of the blood, which has proved that the *Spirochæta pallida* is rarely found in this liquid. The milk of syphilitic women, and the sperm, did not contain the active virus, as the experiments upon *Macacus cynomolgus* were entirely negative. They inoculated a "papiou" with the centrifugized sediment of the semen from a person with a chancre of the foreskin, and lenticular papules of the arms and genital organs. Three weeks after inoculation the monkey showed an initial lesion. In one other experiment

they used the semen of a person presenting double interstitial orchitis (syphilis dating back three years) and the result was more marked than in the first. They also succeeded in engrafting syphilis upon inoculated monkeys if they inoculated the virus five days after the appearance of the primary lesion. Later than this (five days) immunity begins to manifest itself in the animal and it is impossible to obtain positive results. They also find that there is an absence of absolute immunity of the skin in the course of secondary and tertiary lesions. They then inoculated large quantities of the virus in subcutaneous pockets and they have seen not only in the course of the eruption, but also during the tertiary stage local lesions that were syphilitic in nature. They made control experiments with heated virus with negative results. These experiments confirm the work of Neisser (recent meeting of Congress of Dermatology, held at Berne) and also the observations of Metchnikoff and Roux, of Finger and Laudsteiner, of Kraus, Neisser's collaborators, Halberstadter and Baerman, and Siebert. Among these last the most important have certainly been those who have proved that the active virus is in the tissues as the marrow, spleen, lymphatic nodes, and testicles of the inoculated monkeys. Neisser found that eight hours after the inoculation, if the scarified area was extirpated it hindered only the development of primary syphilis; as in this short space of time the microbe of syphilis had invaded the surrounding tissues, and infiltrated very rapidly all the organs. He also found that previous to the development of the chancre the bone marrow and spleen contained the active virus of syphilis and it was inoculable into sensitive monkeys. This seems to prove the inefficiency of extirpation of the primary lesion.

Salmon (*Comptes rendus de la Société de biologie*, lxii, p. 254, February 16, 1907) remarks upon the work of Finger and Laudsteiner upon the re-inoculation of tertiary syphilitics being followed by the formation of lesions reproducing the aspect of tuberculous and ulcerating syphilides. He has obtained positive results in only two out of fourteen instances, and these were papulosquamous eruptions of contestable nature. He concludes that "the immunity coexists with persistent infection indefinitely; and that the syphilitic possesses an absolute cutaneous immunity against reinfection from the outside."

Siegel (*Centralblatt für Bakteriologie*, liii, March 5, 1907, also March 21, 1907) says he was the first to show that syphilis could be inoculated into the rabbit; that he was the first to show that the organs of inoculated monkeys contained the active virus; he alleges priority for the inoculation of the virus under the skin, and that he was able to obtain with great frequency the cutaneous manifestations in the chimpanzee; and that the examination of the internal organs, and especially the liver, should be carried out to consider the infection of a specific nature.

Hans Bab (*loc. cit.*) did not succeed in infecting apes by inoculating them intravenously, intraperitoneally, or subcutaneously, and expresses himself as being surprised that the intravenous inoculations were negative, as congenital syphilis offers itself as an

exquisite example of a blood infection. Rubbing the virus into the femoral vein and into incisions into the lymph glands also proved without result. In two instances inoculation into the parenchyma of the testicle was followed by syphilis in the ape. The first animal became resistant toward a second attack. The second ape was killed after thirty-six days, and with the bone marrow, two other monkeys were successfully infected. Those animals inoculated subcutaneously showed, without doubt, toxic symptoms, emaciation, cachexia, and high mortality. The *spirochætae* are by no means always present in the liver and spleen swelling, and this condition is perhaps caused by its toxine. He states that the penetration of the virus into the abdominal cavity may occur through the tubes, and that it is also possible that the virus may be mixed with the semen in the prostate or urethra.

#### Cultivation.

Leuriaux and Gelts (*Centralblatt für Bakteriologie*, xli, p. 684, 1906) in forty-two lumbar punctures obtained growths of *Spirochæta pallida* in three instances. One part neutral bouillon was added to 2 parts spinal fluid and the mixture placed at 37° C. for several days; centrifugalized twenty minutes, and then the sediment spread over coagulated pork serum. An ivory white, moist film was the result. Smears from young cultures showed bodies like *Cytorrhycles luis*, then a trypanosome, then a *spirochæta*.

De Souza, Jr., and Pereira (*Berliner klinische Wochenschrift*, 1905, No. 44) tried cultivating the organism in 5 per cent. each of sodium citrate and sodium chloride, but with negative results.

Bertarelli and Volpino (*loc. cit.*) failed in all efforts to cultivate the organisms, as did Mühleus (*loc. cit.*).

#### Remarks.

From the résumé of the literature herein recorded, though by no means complete, it seems that the majority of observers look upon the *Spirochæta pallida* as the probable cause of syphilis. I have been able to collect references of 1,210 lesions, including congenital syphilis, and in this number the parasite was present in 958. To enumerate still further it may be mentioned that of 333 chancres examined positive results were obtained in 299 and negative findings in thirty-four. Of forty-three papular eruptions thirty-five were positive and eight negative; of thirty-three mucous patches twenty-three were positive and ten negative, while of 122 roseola eighty-seven proved positive and thirty-five negative. In the lymph nodes, or more properly, the juice of the nodes, only six positive findings are recorded of twenty-four examined. Of thirty-five condylomata, twenty-two were positive and thirteen negative. Of 435 cases simply described as syphilitic, not definitely setting forth the lesions, 361 were positive. Of gummata there were records of only eleven being studied, two of which were positive and nine negative; in forty-seven cases of tertiary syphilis examined negative findings were recorded in all. By far the highest percentage of positive findings were in cases of congenital syphilis, for out of 221 instances of this form of the malady, in 123 the parasite was found.

My own personal observations have convinced me

that the *Spirocheta pallida* is the probable cause of syphilis. In congenital syphilis though the organism has been found most constantly, it is not always generally distributed in all the organs and tissues. It may only be demonstrable in one or two organs as the spleen and liver, or in the kidney, or skin, and then only in certain areas of these structures.

Anyone who has had histological training should not mistake the parasite when stained by the Levaditi method, for any tissue fibres in the different organs, while in spreads from lesions or organs it most certainly takes a practised eye to distinguish between delicate shreds of tissue and spirochaeta, especially when stained by the anilin dyes or any of the stains for blood.

Another point must also be borne in mind, and this is the certain disappearance or diminution in the number of parasites, when local or general treatment is resorted to. The examination should be made as early as possible, and I believe that the best stains to use for spreads from lesions or organs are Giemsa's azure eosin and the blood stain of either Wright or Leishman.

2330 NORTH THIRTEENTH STREET.

#### CASE OF AORTIC REGURGITATION AND FLOATING LIVER.\*

By E. F. MAGRUDER, A. M., M. D.,  
Washington, D. C.,

Medical and Surgical Associate at the Emergency Hospital.

CASE.—G. W. R., male, aged fifty-three, laborer, married; habits temperate, especially as to alcoholics.

History.—His father died of pneumonia, aged about forty-five; mother died at seventy-three, cause unknown; he had three brothers and two sisters, all dead; oldest brother died at fourteen, of diarrhoea; second, at seven, of smallpox; third at thirty, of sunstroke; one sister died at twenty-five, of sunstroke, the other at forty-four, effects of a fall.

The patient had measles and whooping cough in childhood; occasional chills and fever at twenty; about sixteen years ago he had an attack of articular rheumatism, and four years later another attack of the same disease, neither of which, he says, occasioned any serious illness. For the most part he has enjoyed good health, and always worked hard.

His present illness began November 20, 1905, after a hard day's work, lifting heavy stones in a quarry, where he had been working for some months. In the evening as he started homeward he noticed for the first time an unusual sound like the rubbing together of his overalls, but it came from his chest. Shortness of breath upon slight exertion soon followed. He consulted a physician, who told him he "must be more careful with himself and not do any heavy work." So far as could be learned he had been given digitalis.

He consulted the writer at the Emergency Hospital, Washington, D. C., in May, 1906. Examination.—This showed at that time a hepatoptosis and cardiac disturbances so grave that patient was advised to enter a hospital for treatment. He complained of dyspnoea, anorexia, bronchitis, broken sleep, loss of weight and strength; there were arterio-sclerosis, oedema of lower extremities, albuminuria 0.2 per cent., bronchial blood pressure 228 millimetres, great anxiety.

Present State.—Patient is about 5 feet 6 inches in height, muscular, erect, general appearance good; skin normal, no oedema or eruption; pulse arrhythmic, about 80; arteries somewhat tortuous, sclerosed; sphygmomanometer registered only 155; pulse strong, at times "Corrigan." Respiration 22, frequently arrhythmic. The striking symp-

ptoms are cardiac rather than hepatic. He complained of palpitation of the heart and a mild soreness upon pressure over the epigastrium.

He has occasional headache, sleeps well, no disturbance of sensation or motility. Buccal membranes markedly pigmented; tongue of good color; circumvallate papillae extraordinarily developed; appetite excellent; no thirst or vomiting; bowels regular, no gastropnoea. Respiration 22, rhythmical; occasional cough and expectoration; microscopic examination of the sputa shows the so called "heart disease cells"—i. e., alveolar epithelial cells, containing numerous hematoidin granules (first observed by Virchow). Urinalysis is negative.

Fluoroscopic.—No apparent enlargement of the right heart, but considerable enlargement of the left ventricle. The usual shadow of the liver is entirely absent.

Ætiology.—Cardiac: The following may be cited as conditions contributory to aortic regurgitation: 1. Acute endocarditis, attended with extensive ulceration, usually terminating in speedy death. 2. Syphilis, of which there is no history in the case before us. 3. Chemical irritants, such as uric acid, lead poisoning, alcohol—none suspected here. 4. Chronic endocarditis, affecting the aortic valves by direct extension of aortic endarteritis. We must remember, however, in this connection, that arteriosclerosis, present in this case, may be secondary to chronic valvulitis. 5. Pronounced dilatation in the ascending portion of the arch near the valve, which is rare; or an aneurysm just beyond the aortic orifice—neither of which could be observed in the fluoroscopic examination here. 6. Age and sex; much more frequent in males than females, primarily because a greater proportion of the former is engaged in occupations causally related to the disease. The great majority of cases arises in advanced middle life, a relatively smaller number in still later years than that found in young adult life. My patient is fifty-three years of age. 7. Augmented aortic tension strain. Occupation is more noteworthy than alcohol as a cause of aortic regurgitation by increasing vascular tension. We cannot deny that strong bodied men at middle life engaged in such occupations as demand strain—"not a sudden, forcible strain," says Osler, "but a persistent increase of the normal tension to which the segments are subject during the diastole of the ventricle—are the most frequent subjects of aortic regurgitation." This observation is of exceeding significance in the history of the case before us. "I was at Cleveland Park," says the patient, "engaged in lifting heavy stones." This work had been kept up for some months, there was "a persistent increase of the normal tension to which the segments were subject during the diastole of the ventricle," and up to that particular hour when his mental vision became perforce introspective, when this loud cardiac murmur for the first time caught his ear, the patient did not know he had a heart.

Ætiology.—Hepatic: Floating liver is very uncommon. So far as the writer has been able to learn there have been but eighty cases reported in the literature. About ten years ago J. E. Graham collected seventy cases from this source. Since then about ten more have been added. Nearly all have been females. The organ moves slightly in the pendulous abdomen of enteroptosis, and in cases of ascites repeated. At the posterior margin the organ is so bound to the inferior vena cava and diaphragm that

little mobility at this point is possible except in case of a mesohepar or a congenital ligamentous union of these structures. The suspensory and triangular ligaments may, however, be subject to considerable relaxation, the former three inches, the latter one and three-fifths inches, and, in the erect position, permitting the organ's upper surface to lie almost below the costal margin, as in the case before us. When the organ is tilted forward a very large surface of the lobes comes in contact with the abdominal wall, and the error in such instances is by no means rare to think that the organ is enlarged. Such, possibly, is the case in point, for the writer is much of the opinion that the dull soreness upon pressure over the epigastrium complained of by the patient, and for the relief of which he had been treated for indigestion, is due almost entirely to traction upon the suspensory ligament, for no better reason than that the abdominal bandage recommended by the writer gives absolute relief, the symptom returning as soon as the patient attempts to go without it.

It will be understood, of course, that in raising the liver, not only is traction upon the suspensory ligament, upon the connective tissue which unites the uncovered area of the right lobe of the liver to the diaphragm, and, as observed by Fauré, the traction upon the hepatic veins which join the vena cava—not only are they all relieved, but, what is of infinitely more interest to my long suffering patient than all this high sounding phraseology, is the fact that, in elevating the liver the stomach likewise is elevated, and traction upon the gastrohepatic omental attachment to the lesser curvature is prevented, and the patient is at ease.

**Symptoms.** Shortness of breath upon exertion; dyspnea, especially at night; pain over epigastrium; at times, cough; occasionally, vertigo.

**Physical Examination.—Inspection.**—His thorax is well developed and muscular; apex beat displaced one interspace below and two and three sixteenths inches to the left. There is a slight precordial bulge.

**Palpation.** There is a terrible heaving cardiac impulse, a very distinct purring thrill diffused over an area of three inches square at the base of the heart. **Mensuration.**—The left thoracic segment is greater than the right by five eighths inch. **Percussion.**—This gives considerable increase in the area of cardiac dullness, extending downward and to the left. **Auscultation.**—There is a loud diastolic murmur, with seat of maximum intensity at the sternal border of the second right interspace, transmitted anteriorly and posteriorly over the entire thorax and abdomen, from the clavicles above to the pelvic brim below, clearly heard also in the vessels of the neck and the femoral artery, completely obliterating the usual myocardial and valvular sounds. It is a loud, long drawn bruit, almost a moan, and the writer takes it, of course, as caused by the reflux of blood from the aorta into the ventricle. Frequently replacing this diastolic murmur is a reduplicated or double murmur, iambic in rhythm, the one diastolic, the other exactly presystolic in time. This last the writer takes for a "flint" murmur.

The flint murmur, as explained by himself, is due to an extreme dilatation of the ventricle, as a result of which the mitral segments during diastole are forced back against the wall, and, therefore, lying in the blood current, they produce a sort of relative narrowing, the result of which is a vibratory murmur in character not unlike the presystolic murmur of mitral stenosis.

Broadbent's theory in this regard is to the effect that the regurgitant current from the aorta, imping-

ing upon the anterior or aortic flap of the mitral valve, may set it into vibration and thus produce the murmur. While Osler observes: "This apex diastolic murmur of aortic insufficiency occurs in a considerable proportion of all cases." "It is variable and may disappear as the dilatation of the ventricle diminishes."

Let us look for a moment at our patient's arteries. There is visible pulsation in the peripheral vessels. The carotids throb forcibly, the temporals dilate, the brachials and radials expand with each heart beat. They have a characteristic jerking quality. The throbbing carotids in the neck suggested aneurysm, and led to the fluoroscopic examination. Notice the suprasternal notch and the great vessels beneath the right sternocleidomastoid; see the abdominal aorta lift the epigastrium at each systole, and feel the great prolapsed liver mass pulsate with the expansive force borrowed from the same source; look more closely for the capillary pulse, seen through the finger nails; grasp the forearm above the wrist, and, holding it high, feel the Corrigan or water hammer impulse forcibly strike the palpating finger with its quick, jerking effect, and its immediate recession or collapse; then observe that short but appreciable interval between the heart shot and the fall of the bullet just as it strikes the radial bulb's eye—in a word, observe this symptom complex, and tell me if this is not aortic regurgitation?

**Abdominal Inspection.**—The lower edge of the liver is seen as a distinct linear prominence, extending transversely from the right mammary line almost to the corresponding line on the opposite side. **Percussion.**—Relative dullness of the upper border of liver, right side, is at sixth interspace in the mammary line, eighth in midaxillary, eleventh in scapular line. Lower border of hepatic dullness, right side, is on a horizontal line with the umbilicus, curving an inch above the umbilicus at the median line, and extending two inches beyond this to the left.

The vertical width of hepatic dullness is as follows: On the right in mammary line, six inches; in midaxillary line, five inches; in scapular line, three inches; in anterior median line, seven inches; in left parasternal, six and one half inches.

**Palpation.**—An extensive hepatic area is easily palpable. By Glénard's *procédé du pouce* the edge of the organ may be felt to slip above the fingers with the respiratory movement. Its character is smooth and soft. The organ distinctly pulsates. It is freely movable from side to side and from below upward.

The physical signs of the stomach are those of a slight dilatation; the spleen is a trifle enlarged. There is no perceptible abdominal tumor except the liver mass. The kidneys are apparently in their normal position, and either may be felt on deep palpation. As stated before, the condition here is not that of enteroptosis.

**Diagnosis.—Cardiac.**—The diagnosis of aortic regurgitation is based upon a diastolic murmur over the aortic area, throbbing arteries, the peculiar pulse, hypertrophy of the left ventricle, and the sphygmographic charts.

**Diagnosis.—Hepatic.**—Floating liver is the diagnosis, made upon the presence of a large tumor in the abdomen, in this case easily distinguishable from tumefaction of the other abdominal organs for the following reasons: 1, The notch is palpable; 2, there is a tympanic note over the normal hepatic region; 3, the unusual mobility of the tumor; 4, it is possible to replace the organ; 5, its size and consistency; 6, the relatively long chest and lax recti muscles, favorable to the condition; 7, the confirmatory fluoroscopic examination, showing the total absence of the shadow as produced by the upper border of the normal liver.

**Prognosis.—Cardiac.**—Eventually unfavorable, though compensatory hypertrophy may go hand in hand with dilatation, and, while subject to sudden death to a larger degree than results from any other valvular lesion, one may, in the practice of moderation, live for years. This condition following endocarditis, however, is much more favorable than when dependent on arteriosclerosis. The heart, complicated with the use of the patient's body for twenty days, with progressive aortic regurgitation, the first case on record, upon the prognosis was very exact, namely, that degeneration and death in the end.

Prognosis.—Hepatic. Favorable.

Treatment.—Hepatic.—Mechanical support, a snugly fitting abdominal bandage, preferably of linen, and with straps passed around the buttocks, like a suspensory bandage, to prevent its riding above the hips.

Treatment.—Cardiac.—The writer protests against digitalis as a routine stimulus for cardiac failure. In dilatation—when by its use slow regularity supplants the many ineffective contractions of the overdistended ventricle, this followed by cardiorespiratory rhythm and the absorption of pulmonary oedema—digitalis produces striking effect. It is powerless, however, in fatty degeneration. It disturbs the stomach, and acts on the muscular arterioles as it does on the ventricle, and thus in arteriosclerosis increases an already too high tension. Nitroglycerin will counteract this undesirable vascular effect of digitalis by dilating the arterioles, while it stimulates cardiac systole.

Strophanthus—almost free from the contracting effect of digitalis upon the arterioles—is preferred, with strychnine sulphate and nitroglycerin as adjuvants.

A grain and a half of caffeine citrate is better than larger quantities, for in some cases long continued administration of three or four grains occasions cardiac arrhythmia and distress. Sparteine sulphate in doses of three quarters or one grain, combined with caffeine and strychnine, often acts better in aortic regurgitation than either digitalis or strophanthus.

Since muscular power is directly proportional to the amount of oxygen consumed, the patient is advised to spend as much time in the open air as the weather will permit. Iron, because a great oxygen carrier in the blood and a preventive of loss as regards the contractile power in hypertrophied muscles, has been added. Meat, because of the high tension pulse, has been largely interdicted, and the value of milk, vegetable diet, and fresh fruit emphasized. Beans, asparagus, and fibrous vegetables, as cabbage, turnips, and beets, are denied.

Constipation, raising the tension of the abdominal arteries, is prevented by the use of magnesium sulphate and sodium phosphate—one to two teaspoonfuls in a cup of hot water on rising.

But strong medicines have been allowed only a secondary rôle. With sufficient stimulation to keep the heart going, emphasis has been laid rather upon the importance of hygiene, diet, and rest.

Under this treatment the patient's blood pressure has fallen from 228 to 155; he has gained sixteen pounds in weight; oedema of the lower extremities has entirely disappeared; no trace of albumin is found in the urine; compensatory hypertrophy seems established, and his general improvement is certainly quite marked.

#### DISCUSSION.

DR. THOMAS A. CLAYTOR said that the hepatoptosis was very interesting and very rare. He has seen three cases, including that presented by Dr. Magruder; one was seen in Philadelphia and another at the Garfield Hospital here.

DR. LOUIS MACKALL, JR., said the case was of great interest, particularly on account of a presystolic thrill at the apex with no apical murmur, and the presence of the loud murmur at the base with no basilar thrill. The condition suggested to him aneurysm of the heart. The heart was not much hypertrophied, and on that account he did not think that the aortic regurgitation was of long duration. He believed that the condition of greatest moment was the hepatoptosis, which by pressure and drag on the aorta threatened or had already caused aneurysm. On that account he would urge suspension of the liver after the manner described by Le Page. Dr. Mackall believed that such an operation was strongly indicated in this case, in which the heart was already in bad condition and progressively growing worse.

DR. J. D. THOMAS said that the conditions under which he had examined the patient did not justify an accurate diagnosis. The murmur was a very unusual one, and though at first it seemed to be systolic, when compared with the pulse, it proved to be diastolic in time, or at least not systolic. Although the sounds did not indicate to his mind aortic regurgitation alone, that condition was present. A pathognomonic sign of that lesion is a double bruit in the large vessels, and that sign was plainly audible

in this case in the femoral artery. Some writers hold that the sign may also be heard in mitral stenosis. The case was of great interest, but he did not think that the sounds were altogether characteristic of aortic regurgitation alone.

DR. E. P. MAGRUDER, in closing, said that with regard to the thrill it might be felt at base and apex. He had referred in his paper to the double vascular murmur mentioned by Dr. Thomas. He did not think there was any involvement of the right heart. He agreed that possibly the mitral valve also was affected, producing at times the reduplicated or double murmur effect described by Flint as replacing that of simple aortic regurgitation. As to the time of the murmur careful study had convinced him that it was diastolic. He had no opinion to offer as to the relation between the floating liver and the cardiac condition.

In the course of the last year evidences of arteriosclerosis had increased. The pulse had also markedly changed in character, due no doubt to improved mode of living.

THE ASHLEY, EIGHTEENTH AND V STREETS.

#### ORTHOPÆDIC THERAPY DURING THE EARLY STAGES OF ACUTE ANTERIOR POLIOMYELITIS.\*

BY JOHN JOSEPH NUTT, M. D.,

New York,

Instructor in Orthopædic Surgery, Cornell University Medical College; Assistant Surgeon, New York State Hospital for Crippled and Deformed Children; Surgeon, Orthopædic Department, Cornell University.

Cessation of spontaneous improvement, without a complete cure of the paralysis, after an attack of acute anterior poliomyelitis, marks the beginning of a chronic stage. It is not the treatment during this stage which it is proposed to discuss here.

Believing, however, that proper and painstaking orthopædic treatment, instituted during the more acute stage, will greatly lessen the extent of the crippling results, and be the means, in some cases, of a complete cure, I shall attempt to discuss such treatment as appears to me to be rational and essential.

The ultimate disabilities are due to the paralysis and to the deformities. The deformities result from unopposed muscular action, from asymmetry in development, and from weight bearing in an abnormal position while the sustaining tissues have their motor and trophic centres paralyzed. The treatment, therefore, before the chronic stage, should be directed toward: 1, Keeping the parts in as healthy a condition as possible; 2, the preservation of the normal range of motion in all the joints; and, 3, preventing stretching and elongation of paralyzed and weakened tissues.

1. To keep the parts in as healthy a condition as possible. The importance of this cannot be overestimated. It must be borne in mind that, in these cases, the paralysis is not only a motor paralysis, but a trophic paralysis. Not only do the muscle fibres lose the influence of their trophic centres, but every tissue, bone, ligament and blood vessel suffers from this paralysis.

The means to be used to combat this condition are massage, electricity, heat, and hydrotherapy.

\*Read before the Society of Alumni of Bellevue Hospital, January 2, 1909.

Directions to simply rub the muscles every day are not sufficient. The failure of most American physicians to appreciate the value of scientific massage, and their unwillingness to do it themselves, is a serious loss to our armamentarium. Massage should be done daily, conscientiously, scientifically. Each séance should occupy from ten minutes to one half hour, depending upon the age of the patient and the parts to be massaged. Friction alone is insufficient. Each paralyzed muscle should be stripped of its blood supply and its capillaries engorged with fresh blood.

Electricity is of use in this as well as the later stage. If there is any response to the faradic current it may be used, otherwise the galvanic current is employed. A very few minutes, perhaps three or five to a muscle, of skillfully applied electricity, daily, is undoubtedly of great service toward combating the effects of both the motor and trophic paralysis.

The local temperature should be maintained. This is often a difficult matter. Hot water bags and electric heaters are not to be recommended, as the lowered temperature is not a temporary condition. It is best maintained by preventing loss of heat through radiation and conduction. Extra clothing, constantly worn, may accomplish this, but, if not, then wrapping in cotton batting or other means must be taken.

Hydrotherapy is of value as a stimulant to the vasomotor apparatus and also as a means of preserving the skin in a healthy condition. On account of the trophic disturbance to the skin and its consequent liability to ulceration, care must be observed in the use of soaps. The alternate hot and cold douching with sea salt solution is often most happy in its results. If, however, a reaction is not at once evidenced, the douching should be discontinued.

2. Normal range of motion at the joints is preserved by passive movements. These should be carried out daily from the beginning of treatment. Muscle shortening begins within a very few weeks. Normal movements may be impossible, without the use of force, as early as six weeks after the onset of the disease, as seen in a case this fall.

This shortening of the muscles and the subsequent ligamentous shortening is due to the physiological law enunciated by the late Henry G. Davis, in his *Conservative Surgery*, page 130:

"Ligament, or any soft tissue, when put under even a moderate degree of tension, if that tension is unremitting, will elongate by the addition of new material; on the contrary, when ligaments or other soft tissues remain uninterruptedly in a loose or lax state they will gradually shorten as the effete material is removed, until they come to maintain the same relation to the bony structures to which they are united that they did before their shortening."

3. To prevent stretching of paralyzed and weakened tissues: The paralyzing effect of overstretching a muscle is known to all physiologists, but, I believe, its importance as a factor in determining the amount of disability resulting from infantile paralysis is not sufficiently emphasized by surgeons. It has been demonstrated, time and again, that the application of an apparatus relieving muscles, which had been classed as paralyzed from the cord lesion

from a long continued and uninterrupted stretching force, has produced some return of power. Even after several years of nonuse from overstretching muscles may, by proper treatment, be partially restored to their normal functions.

It is to be remarked that of all the groups of muscles which may be paralyzed after an attack of acute anterior poliomyelitis, the muscles which receive the greatest strain, under ordinary circumstances, are the ones which, in the majority of cases, remain as the only reminiscence of the disease. In paralysis of the anterior tibial muscles, whether the patient is lying down or sitting up, those muscles are on a stretch the greater part of the time. Not only is gravity stretching them, but the calf muscles, providing they are not paralyzed, are constantly exerting a stretching force. To avoid this, passive movements once or twice a day are not sufficient. The ends of the dorsal extensors of the foot must be approximated and held in that position unremittingly, except for the short time that other treatment is being given. This should be done as soon as these muscles are found to be paralyzed. The same precautions should be taken to prevent stretching of any muscles, such as the peronei, the tibialis anticus alone, or the deltoid.

To illustrate the importance of preventing this stretching paralysis, which is so frequently classed as due to the cord lesion and considered permanent, I shall briefly relate a case which was recently sent to me from up the State.

CASE I.—L., thirteen years old. Family history was good. Previous history was negative. Present history: In August, 1905, patient had an attack of what was diagnosed as acute anterior poliomyelitis. Condition in September, 1907: There was paralysis of tibialis anticus of right leg, of all the anterior tibial muscles of the left leg, and probably the intrinsic muscles of the vertebrae, which produced a lateral curvature. During three months of daily treatment of the scoliosis her paralyzed leg muscles received, also daily, massage, electricity, extension of contracted gastrocnemius of left leg, douching with hot and cold salt solutions, and passive and, where possible, resisted active motions. A very slight reaction to the faradic current was present, at the beginning of treatment, in the muscles of the left leg, but none in the right tibialis anticus. At the present time all the muscles of the left leg, which had been considered as permanently paralyzed by destruction of the anterior horn cells, show a return of power. The right tibialis anticus is probably paralyzed from the destructive process of the disease.

Another instance, to my mind, of paralysis due to overstretching was the following:

CASE II.—Last summer a gentleman consulted me regarding his chauffeur. I found the young man, then twenty-one years of age, had a paralysis of the anterior leg group of the right leg. He had had this trouble as long as he could remember and had been treated at dispensaries in New York city for a number of years. The treatment had consisted only of braces which he had worn only intermittently. One year had he been in bed, and for the last year he had been a chauffeur, he had used the foot constantly on pedals and had found that he was obtaining some use of his toes. The pedaling, making a forced dorsal flexion, would have tended to stretch the contracted gastrocnemius and this may possibly, it would seem, have been sufficient to relieve the strain on the dorsal flexors, and permitted some return of power.

Contrary to the opinion of some, prolonged rest in bed does not appeal to me as the wisest of treatment. After the subsidence of the fever, every measure which will help to restore a normal circula-

tion to the cord and place the constitution of the patient in the best possible condition, are to be employed. When the question of applying a brace, therefore, arises, serious consideration must be given as to whether the importance of supporting a weakened joint or muscle overweighs the concomitant confinement of other joints and muscles. Functional use of muscle, ligament, and bone are to be encouraged. Great care is necessary while spontaneous improvement is progressing that an apparatus does not do more harm than good. Hard and fast rules cannot be laid down. Consideration must be taken of the age of the patient, his activity, and the strength of the supporting structures of the joint. A child unable to walk, either because too young to walk or from disability, will need, if any, but simple apparatus, while an active child, continuously on his feet, and using his legs as best he can, may need protection while yet his condition is perceptibly improving. In all such cases, the muscles and joints which are confined should receive exercise by passive and resisted active movements twice a day, with the brace removed.

"THE SEMINOLE," BROADWAY AND SIXTY-NINTH STREET.

#### A CASE OF BILIARY FISTULA BETWEEN THE GALLBLADDER AND THE STOMACH, WITH A STONE IN THE HEPATIC DUCT.

By GEORGE MORRIS DORRANCE, M. D.,

Philadelphia,

Surgeon to St. Agnes' Hospital.

In reviewing the literature of biliary fistula one is struck by the rarity of fistula into the stomach. Naun mentions that twelve cases had been reported, but only gave the references to nine (Courvoisier eight, Schlorth one); Moynihan records one, the Middlesex Museum one (No. 1595), Mayo Robson one, Oppolzer one, French one, and Jaefreson one. Undoubtedly many more have been recorded, but I have been unable to find them.

The history of my case is as follows:

Patient was seen in consultation with Dr. W. P. and Dr. E. M. Kistler, of Allentown, Pa. She was a woman, forty-seven years of age. Family history was negative; previous personal history also negative; no history of typhoid fever.

History of present illness: Patient had had three attacks of biliary colic in the past four years, accompanied by jaundice in two instances, but no gastric disturbances. The present attack began with pain in the gallbladder region without being transmitted. Jaundice was intermittent for the past eight days; at the time of operation the patient was slightly tinged.

Operation: On opening the abdomen, the anterior wall of the stomach, 6 centimetres from the pylorus, was adherent to the lower surface of the gallbladder, 1 centimetre below the apex. Very few adhesions were present. With the finger in the foramen of Winslow, the common duct was found free from stones, while the hepatic duct was obstructed by a large faceted stone. The stone was "milked" down and removed from the hepatic duct. The gallbladder was opened, and the little finger passed into the stomach through the fistula. The gallbladder was drained with a rubber tube, and the wound closed, except for a large gauze drain. The fistula was not closed, but left as I found it.

Subsequent history: The wound healed in three weeks. No gastric disturbances have occurred since, and the patient reports that she is entirely well.

### Our Readers' Discussions.

#### A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows:

LXXI.—How do you treat gallstone colic? (Closed February 15, 1908.)

LXXII.—How do you treat fracture of the patella? (Answers due not later than March 16, 1908.)

LXXIII.—How do you treat seasickness? (Answers due not later than April 15, 1908.)

Whoever answers one of these questions in the manner most satisfactory to the editors and their advisors will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred words.

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. All papers contributed become the property of the JOURNAL.

The prize of \$25 for the best essay submitted in answer to question LXX has been awarded to Dr. Beverley R. Tucker, of Richmond, Va., whose article appears below.

#### PRIZE QUESTION NO. LXX.

##### THE DIAGNOSIS OF ALCOHOLIC STUPOR.

By BEVERLEY R. TUCKER, M. D.,

Richmond, Va.

A medical student, cramming for some examination, learns a long list of distinctive diagnoses of stuporous states arranged for his edification in columns side by side. This table he quickly forgets or his impressions become sadly confused. In consequence of this he may thereafter have the embarrassing experience of being brought face to face with some case of unconsciousness and be at a loss to diagnose or treat it. I shall attempt rather to give only a brief picture of states that may be mistaken for alcoholic stupor.

The conditions we will consider are: 1, Alcoholic stupor. 2, Epilepsy. 3, Spontaneous cerebral hæmorrhage (apoplexy). 4, Cerebral trauma with stupor. 5, Heat stroke. 6, Uræmia. 7, Shock. 8, Diabetic coma. 9, Cardiac syncope; 10, Narcotism. 11, Hysteria and hypnotic states. 12, Malingering.

As aids to diagnosis, we should note the time of day or night when we first see the case, the surroundings, whether or not the patient is alone, and note the posture, general appearance, and complexion of the patient. See if marks of violence or injury are present, and notice if any weapons, bottles, or papers are lying about. We should feel the pulse and skin, and note the character of his breathing, the reaction of his pupils, and whether his limbs are stiff or relaxed, and whether there is any odor about him. We also must bear in mind that in organic cases the preponderance of symptoms are on one side, while in toxic conditions they are bilateral. All this will take but a few moments, and then we begin to classify our case.

1. *Alcoholic stupor*.—If the odor of alcohol is present it is not a reliable sign, but the absence of this odor is a valuable negative diagnostic point. The patient is usually lying on his face or side, and

his limbs are flaccid and partly flexed. Pressure over the supraorbital notch or ammonia inhaled will arouse him. If the extremities move it proves that part not paralyzed. He has no convulsions, and his knee jerks are usually absent. The pupils are dilated, but react to strong light. If cardiac compensation fails his face is pale and pulse weak, but usually the face is flushed, the skin damp, and the pulse full and rapid, though of low tension. His breathing is heavy, he mutters when aroused, and his temperature we may expect to find subnormal.

2. *Epilepsy*.—The convulsion itself is not mistaken for alcoholism, but the stuporous stage following may be. The history of an immediately preceding fit, and especially of the past occurrence of others, is a valuable point. A bitten tongue, froth on the mouth, and the absence of alcoholic odor separate the two conditions. The temperature in epileptic stupor is usually normal or slightly elevated. The knee jerks are abolished, and the pupils dilated and immobile, but these reflexes return as the patient becomes conscious.

3. *Spontaneous cerebral hemorrhage (apoplexy)*.—This occurs most frequently in people past middle life, who are high livered and who present evidence of arteriosclerosis, but it may occur when none of these conditions obtain. The pupils are dilated, but, unlike alcohol, do not respond to light. The blood pressure is increased, and there is paralysis of one side, the leg on this side being more flaccid and extended than on the healthy side. The Babinski sign is also found on the hemiplegic side. The knee jerks may be plus, minus, or absent, but the superficial reflexes are decreased. The temperature is subnormal and then rises. The cerebrospinal fluid contains traces of blood. If the hemorrhage is pontine the pupils are contracted, the symptoms bilateral, and there is marked perspiration, although the temperature is high. In cortical hemorrhage the muscles are spastic and deep reflexes increased.

4. In *cerebral trauma with stupor* the symptoms of concussion and laceration are similar, compression is different. In the first two the skin is pale, cool, and clammy, the pulse weak, the knee jerks abolished, the temperature subnormal, and the respiration feeble. Concussion may go to cerebral irritation of the frontal lobes, and the patient be excited, restless, lying in a curled up position, and roll from side to side. In compression the patient lies on his back, the skin is damp and hot, the pupils vary, the skull may show the depression, and there may be focal paralysis.

5. *Heat stroke*. The atmospheric conditions are extremely high body temperature, sometimes to  $112^{\circ}$  F., and the very flushed dry skin will usually be sufficient to distinguish.

6. *Uremia* presents albumin and casts in the urine, and the face may show a swollen pallor and the breath be uræmic. This condition is usually preceded by headache, vomiting, and convulsions.

7. *Shock*—see the history in the case of difficulty. The face is expressionless and pale, the temperature subnormal, the skin cool and the pulse weak and running.

8. *Diabetic coma*.—Sugar is found in the urine, which is of high specific gravity, and there is a

sweetish, acetone odor about the breath. If coma is deep the pupils do not react. The pulse is small and rapid. Headaches and drowsiness precede.

9. *Cardiac syncope*.—This condition, known to the laity as a fainting spell, need be only slightly considered. The attack is sudden, and lasts but a short time, the pulse slow and very weak, and the face pale.

10. *Narcotism*.—This embraces too large a field to be discussed here fully. In opium poisoning the pupils are contracted and do not react, the skin is pale, and the respiration and pulse slow and feeble. In ether and chloroform stupor the odor can be distinguished from alcohol. In carbon monoxide and carbon dioxide gas poisoning the surroundings in which the patient is found help us, together with the weak pulse and feeble respiration. Stupor from chloral is marked by a pale, clammy skin, absent deep reflexes, subnormal temperature, and sometimes pupura hæmorrhagica. The pulse is slow, then rapid and weak; the respiration labored, then weak; the pupils contracted, then dilated toward the last.

11. *Hysteria and hypnotic states*.—Hysteria occurs most frequently in young women; the posture is that of a pose; the patients resist having their eyelids opened; their pupils and pulse are normal, unless the latter is accelerated from exertion. The deep reflexes are present. In trance, hypnosis, etc., the pulse and respiration are slow but regular, the pupils normal, and the muscles not completely relaxed or may be rigid. The temperature and skin are usually normal.

12. *Malingering* may be told by the person over-acting the part, the pupils, pulse, temperature, reflexes being in normal condition.

We should try, if possible, to exclude every other condition before diagnosing alcoholic stupor, and I believe that if we make a thorough examination, picturing the salient features of each stuporous state, rather than trying to memorize extensive lists of signs and symptoms, and arriving at alcoholism by exclusion, we will obviate the many distressing errors that too frequently accompany the diagnosis of this condition.

Dr. John McCutcheon, St. Louis, Mo., says:

The conditions with which alcoholic stupor is most frequently confounded are uræmic coma, apoplexy, and opium poisoning.

In acute alcoholism there is deep flushing, sometimes cyanosis, of the face; the pupils are evenly dilated and react to light; the temperature is normal or subnormal; the pulse is full, regular, and bounding; the breath has a strong alcoholic odor (which is far from pathognomonic, however); the muscular resistance is equal on both sides; respiration is slightly accelerated and deep, but not stertorous; there is often twitching of the muscles, but rarely convulsions; and involuntary evacuation of the bladder or bowels may occur, although unconsciousness is rarely complete. Retinal examinations are negative, and albuminuria, other than of slight degree, is exceptional. The blood pressure is seldom very abnormal.

The clinical picture is somewhat different in chronic cases. The face is flushed or

ily dilated or medium in size. The ophthalmoscope shows the presence of albuminuric retinitis. The coma is deep, and stertorous breathing is the rule. Oftentimes the breath has a urinous odor. There is usually marked edema and puffiness beneath the eyes, the complexion is pale and "pasty" looking, convulsions are of frequent occurrence, and a hemiplegia may be present. A careful examination of the urine is, of course, the most important of all procedures here. In fact, it is a wise precaution to make a brief but exact uranalysis in all cases of coma from any cause. A portion of the bladder contents is withdrawn, with aseptic precautions, using a soft rubber catheter. It is safer to employ two methods for the detection of albumin. I prefer the one devised by Heller and the magnesium nitric test. If negative, an examination for sugar, by Fehling's solution, should follow, in order that diabetic coma may also be excluded. The blood pressure in these cases is high, much over 150 mm. as a rule, and the urine and feces are retained.

Apoplexy is frequently associated with alcoholism of varying degree, consequently the diagnostician cannot exhibit too much care in making a positive differentiation. The face may be cyanotic, but is often of an ashy gray pallor. Unconsciousness is profound; the breathing is stertorous, slow, and irregular at times. The pupils vary. They may be irregular, and are inactive. During expiration the cheeks (especially the one on the affected side) are puffed out, and a blowing noise is made by the lips as the air is expelled and the cheeks collapse. There is usually restriction of the thoracic movements on the paralyzed side. Conjugate deviation is often present. The affected muscles are commonly flaccid and nonresisting, although they may show marked rigidity. The pulse is slow, full, strong, and of high tension, the manometer showing a pressure of 175 mm. or more. The temperature is normal or subnormal at first, later there may be fever. The urine is slightly albuminous at times, but seldom more than a trace. If a fracture of the base exists, as a complication, it is accompanied by ecchymoses, especially in the infraorbital regions, there is escape of cerebrospinal fluid, alone or mixed with blood, from the ears, and signs of external violence, such as bruises and cuts, are present.

The symptoms in a case of opium poisoning are more typical. Here the invariable presence of the contracted "pin hole" pupils is of immense aid. The face is swollen and bluish in color; the respiratory movements are irregular, labored, and greatly decreased in frequency (six or eight per minute at times); the skin is cold and clammy; the pulse is slow, weak, and soft, and the unconsciousness is deeper than in alcoholic stupor. Muscular twitching is absent. If the opium taken was in the form of laudanum its odor is imparted to the breath.

At times an epileptic seizure may be mistaken for the insensibility due to alcoholic poisoning. The brief duration of the attack, the absence of odor on the breath, the presence of convulsions at the onset, if seen, and evidences of wounds on the tongue and bruises on other parts of the body will suffice for differentiation.

Diabetic coma sometimes gives rise to an incorrect diagnosis of acute alcoholism, but an exami-

nation of the urine, as suggested under *uræmia*, will speedily dissolve any existing doubt.

During the heated season cases of sunstroke and heatstroke may fail to be recognized, and the condition ascribed to excessive indulgence in alcohol. The temperature (which should always be taken per rectum here), the skin, and the pulse will give sufficient information for a correct diagnosis. In sunstroke there is a pronounced hyperpyrexia, varying from 105° to 112° F., with a hot, dry skin, and a strong, bounding pulse of high tension. In heatstroke, or heat exhaustion, the temperature is subnormal, the skin is pale, cold, and covered with moisture, and the pulse is thready and weak.

When rendering an opinion in a suspected case of alcoholic stupor the physician cannot be too circumspect. If an error is made it should always be on the safe side, the more serious condition being given the benefit of the doubt.

*Dr. W. Hays, of New York, states:*

Stupor, or semicoma, may be defined as an intermediate stage between somnolence and coma. A partial loss of consciousness, or profound slumber, is present, from which it is possible to arouse the patient only with great difficulty and by earnest entreaty.

It is exceedingly important in all cases, in which such unconsciousness obtains, to make a thorough but rapid examination, and note carefully all physical signs. Failure to do this may result in egregious and serious blunders, as, for instance, the diagnosis of drunkenness, merely because the odor of alcohol may be detected on the patient's breath. It is essential to ascertain the condition of the pupils, whether contracted or dilated equally or unequally, the presence or absence of reaction to light or of the consensual reaction. If the eyelids cannot be readily raised, no true stupor exists. The face should be viewed so as to determine whether unilateral facial paralysis be present. Injury to the head, cuts, bruises, or depressions, must be inquired into. The color of the skin may be important. During extremely warm weather the temperature of the skin should be observed. The mouth and tongue may show injuries from the teeth; froth may be upon the lips. The comparison of the degree of flaccidity of the limbs on opposite sides of the body often gives a clue that aids very materially in diagnosis. If possible, the history of the past life of the patient should be obtained, together with a narration of events immediately preceding the onset of the condition in which found. The temperature, pulse, and the respirations should be noted.

In alcoholic stupor, pressure over the supra-orbital nerve will usually elicit a response, though it may be with difficulty, and the patient will often vehemently protest with words or blows. The face is flushed. An alcoholic odor can be detected on the breath and in the vomitus, if any. Absence of this odor will aid in positively excluding alcoholism. The pupils are equal and either of normal size or slightly dilated and react to light; no lateral deviation. The pulse is rapid, full, and strong. Respirations are normal in frequency, but deep and occasionally stertorous. The skin is very commonly cool

and moist, and the temperature either normal or slightly subnormal, unless delirium is present, when there is a rise in temperature. It is well to bear in mind that a cerebral lesion may be coexistent with the drunkenness, and signs of the former condition must be carefully looked for.

The unconsciousness of apoplexy is usually deeper than that of alcoholism, taking on more the character of a coma. The face is suffused, cyanotic, though sometimes pale. The pulse is full, slow, and of increased tension; the artery often shows atheromatous changes. The respirations are slow, noisy, and stertorous, and oftentimes irregular. Cheyne-Stokes type of breathing may be heard. The cheeks are blown out with spluttering of the lips, more marked on one side than on the other if unilateral paralysis of the face is present. The temperature may be normal or subnormal, though in cases likely to prove fatal fever is noted. The pupils are dilated, often unequal, and do not show reaction to light nor the consensual reaction. When hæmorrhage occurs into the pons or the ventricles, the pupils will be contracted because of the irritation of the nucleus of the oculomotor nerve. Conjugate deviation of the head and eyes or persistent turning to one side, the side on which the hæmorrhage has occurred, may be present. Unilateral paralysis of the face is indicated by the droop of one angle of the mouth, the effacement of wrinkles on the affected side, and the flapping cheek. Greater flaccidity of the limbs on one side may be noted by raising them and letting them fall, those on the affected side dropping as "dead." The skull should be subjected to a thorough examination for any injury, however slight it may be. The onset varies in suddenness, depending on whether the apoplexy is due to cerebral hæmorrhage, embolism, or thrombosis. Stupor or coma, with hemiplegia, complete or incomplete, may occur in the course of pachymeningitis interna hæmorrhagica.

In opium poisoning the patient can be aroused unless he is extremely narcotized. The face is at first pale; later dusky and cyanotic. The pupils are strongly and equally contracted. The respirations are slow, and may even drop to eight a minute. The pulse is slow and full. The temperature of the body is normal or subnormal. The skin is warm and moist. If the intoxication is due to laudanum the smell will be noticed on the breath.

Uræmia is a form of intoxication due to the retention within the circulation of excrementitious substances normally eliminated by the kidneys. The patient may be aroused temporarily from the unconsciousness which may be preceded by or alternate with epileptiform convulsions. The face is pale, swollen, and œdematous. The breath exhales a urinous or sweetish odor. Examination of the urine shows evidence of kidney disease, but that should not lead the physician astray. The pupils are equal and usually widely dilated, though they may be normal and reaction to light be preserved. There may be twitching and tremor of the muscles of the hands and feet. The pulse is rapid. The respirations are frequent and irregular, disposed occasionally being seen, or even Cheyne-Stokes type of breathing. The temperature is usually normal, but

may at times be subnormal. Convulsions tend to elevation of temperature. If ophthalmoscopy is possible, nephritic retinitis may be discovered. Occasional instances of uræmic hemiplegia are met with, which are unexplainable pathologically and are often transient.

These conditions are the most common ones in which a distinctive diagnosis is puzzling, and often, indeed, baffling. In addition, it is well to bear in mind that in hysteria, insolation, epilepsy, diabetes, and gas poisoning, unconsciousness is existent which may easily mislead the careless observer. In hysterical stupor the patient will resist opening of the eyes usually, and the eyeballs are rolled upward. A strong irritant, such as ammonia, held closely to the nose, will always awaken a response. Sudden anæmia of the brain causes an absolute pallor of the face; the respirations are shallow and almost imperceptible; the pulse weak and fluttering, and the pupils much dilated, with the eyes possibly wide open. Thermic fever can usually be distinguished by the excessively high temperature of the body and the history of prostration under exposure to the sun. In heat prostration a greatly subnormal temperature is present, and the unconsciousness may be due to either the sun's rays or to intense artificial heat. In epilepsy, the froth on the lips, possible biting of the tongue or lips, the history of a convulsion, and the gradually subsiding unconsciousness, will clear away any doubts as to the condition present. Diabetes is made distinctive by the discovery of a considerable amount of sugar in the urine and the sweetish, fruity odor of the breath. In poisoning due to illuminating gas, the condition is almost always obvious from the circumstances under which the patient is found. The smell of the gas will usually clear up the diagnosis, though a further criminal aspect may be given to the case by the discovery of wounds that may explain the true condition, complicated by the inhalation of the noxious vapor. Stupor may also be associated with any organic or inflammatory disease of the brain. In eclampsia due to pregnancy, stupor, or coma, preceded by or associated with convulsive seizures, can be readily diagnosed. In many of the acute infectious diseases, such as typhoid, typhus, and pernicious malarial fever, a gradually appearing unconsciousness may develop.

Careful attention to all objective signs will usually lead to a positive diagnosis, but at times the condition seems so obscure that even the most painstaking examination will be vain and fruitless.

*(To be concluded.)*

### Therapeutical Notes.

**A New Treatment for Tuberculosis.**—Lemoine and Gerant, of Lille, read a paper at the Académie de Médecine upon a treatment of tuberculosis, based upon the antitoxic action of the liver (*The Practitioner*, February, 1908). They point out that bile and the biliary acids are known to have a true chemical neutralizing effect upon the venom of the biles, and that cholesterine, in particular, behaves as an antitoxic influence. They made a series of ex-

periments to determine whether cholesterine and bile extracts possess any immunizing properties against the poison of tubercle. Bacilli were injected into the peritoneum of guinea pigs, to which were, later, given hypodermatic injections of cholesterine and of biliary extracts, obtained from the bile by petroleum ether. The injections produced no unfavorable reaction, and a greater resistance to tubercle was noted in the animals experimented upon. There was no development of tubercle. In the wards, Lemoine used the same products for injection, and found in the patients, submitted to the treatment, improved general condition, lessening of the night sweats, of the fever, and of the frequency of the pulse, increased arterial tension, return of appetite, and increase in weight. The results obtained in over 250 patients, treated during the last three years, have been that in tuberculosis of the first and second degree, the improvement has been complete, allowing on an average a return to work in the case of laborers, in from two to three months. In more advanced cases, with cavities and profuse expectoration, the results have been moderate. It is best given hypodermatically.

#### Pyroligneous Acid for Arthritis Deformans.

—In the treatment of arthritic deformities of the joints, Kolipinsky is said, according to *Journal de médecine de Paris*, for December 29, 1907, to give pyroligneous acid internally in doses of from one to two teaspoonfuls, diluted with a small quantity of water, repeated two or three times a day. Under the influence of this medicament the pain and the swelling are said to subside and the joints to regain their suppleness in a very short time.

**Antiseptic Mouth Wash.**—Robin is credited in *Journal de médecine* for December 1, 1907, with the following formula for an antiseptic wash for the mouth and pharynx:

β Betanaphthol, .....	0.02 gramme;
Sodium perborate, .....	15.0 grammes;
Peppermint water, .....	200.0 grammes;
Boiling water, q. s., .....	ad 1.0 litre.

M.

Heat the solution on a water bath, when it is ready for use.

**Extract of Brain Substance Hypodermatically in Tetanus.**—According to M. Uspenoki (*Nouveaux remèdes*, December 8, 1907; *Pharmaceutical Journal*, February 16, 1908), aqueous or glycerin extract, obtained by rubbing down brain substance of any healthy animal with physiological salt solution or with glycerin and filtering through a Berkefeld filter, has given excellent results in the treatment of tetanus with patients ranging in age from six to forty-eight years. The dose given is 15 to 20 c.c. in twenty-four hours, hypodermatically, in the abdominal region; more may be given in grave cases. It is essential that the brain substance used should be quite fresh, and not more than five to seven hours after slaughtering should be allowed to lapse before it is used. When thus active, the results obtained with the injection are at least equal to those following the use of tetanus antitoxine, with the great advantage that the material is always at hand, procurable in a short time, and cheap. The simple method of injection is also preferable to the more complicated proceeding of subdural injection into the sulcus arachnoid, resorted to with the antitoxine;

the latter, too, is often followed by complications. Besides, no pathological elements are introduced into the system by the use of brain emulsion. Good results have also been obtained, it is said, with brain emulsion extract in the treatment of neurasthenia, epilepsy, tabes dorsalis, and in mental affections.

**Abnormal Digestive Fermentations.**—Formerly these were treated by antiseptics, such as benzonaphthol, salol, etc., but Bardet (*Bulletin de thérapeutique; The Practitioner*, February, 1908) has demonstrated the uselessness of these, and has returned to the use of special antiferments to inhibit lactic or butyric fermentation. For lactic acid fermentation he gives ammonium fluoride, a substance currently employed as an antiferment in breweries and distilleries, in solution, as follows:

β Ammonium fluoride, .....	gr. iii to gr. viiss;
Distilled water, .....	3x.

M. Sig.: Tablespoonful after meals.

For butyric fermentation, the double iodide of bismuth and cinchonidine is used in combination with calcium fluoride and prepared chalk.

β Bismuth and cinchonidine iodide, ..	gr. ½ to gr. iss;
Calcium fluoride, .....	gr. ½ to gr. iss;
Prepared chalk, .....	gr. iss.

M. ft. pulv.

Sig.: One powder in a cachet after meals.

Sulphur iodide in a dose of one and one half grain in a cachet is said to be an effective remedy for the fermentations which accompany true flatulence, the eructation at intervals of gas produced in the stomach, as distinguished from that due to air swallowing which is almost continuous, and for which the remedy is of no avail. Precipitated sulphur checks lactic fermentation and stimulates intestinal contractions. It should be given in a dose of fifteen grains mixed with an equal amount of calcined magnesia in a cachet at each meal. Feculent and sugar must be limited in the diet. Uncooked fruit should only be eaten at the beginning of the morning meal.

**A Soothing, Lubricating Application in Cystitis.**—Elice McDonald, in the *Medical Record* for February 22, has found a mucilage of Irish moss of the following composition a useful, soothing application in cases of acute cystitis:

β Chondrus (Irish moss), .....	5iiss;
Distilled water, .....	O.iii.

Wash the chondrus in cold water, drain; wash again and drain. To the washed chondrus add three pints of distilled water and boil for ten to fifteen minutes, stirring frequently. Strain through muslin with expression. To the strained Irish moss add six pints of boiling distilled water and filter. Evaporate the filtrate to one fifth by bulk, cool partially and add gomenol,<sup>1</sup> one per cent. by weight, mix well, and strain through fine white flannel which has been previously boiled.

The author states that the value of this preparation consists in keeping the bladder walls apart and lubricating them, so that no friction or irritation results. The preparation is approximately the same as many lubricating jellies put up in tubes for use in vaginal examination. It is also of use in lubricating the cystoscope before its introduction into the urethra. In bladder treatment the jelly should be diluted with hot water to a thick semisolid consistence, fit for use in a syringe.

<sup>1</sup> Gomenol is made by macerating the leaves of *Gouania glabra* in alcohol, and distilling the volatile oil from the residue, and redistilling the oil from the residue.

## THE PHILOSOPHY OF CHARLATANRY.

All educated and experienced physicians are aware of the fact of the extensive prevalence of charlatantry throughout the length and breadth of the development of human culture, from the most ancient to the most modern of times. Many who have contemplated the history of mankind have been tempted to maintain that little or no advance has been made by the human mind in its attitude toward charlatantry since the days of Homer at least, or even perhaps of the early Egyptian civilizations, glimpses of which are now being obtained with increasing frequency.

The patrons and dupes of what educated physicians call charlatantry are not at the present time confined to any class of men or of women. Even those of the highest culture and refinement seem to follow the lights of false teachers with as much persistence and as little discretion as the most ignorant of people. It becomes all the more interesting, then, to analyze if possible the philosophical foundations of successful charlatantry, with the view of understanding the principles which move so many individuals along lines which must in the end be the opposite of self conserving.

In a recent very suggestive article on this general subject Dr. D. K. Shute, of Washington (*Hygienic-Laboratory Journal*, January), has by no means that at least five factors stand forth as elements of stupendous power in cultivating and maintaining such an extensive field of charlatantry as may be

witnessed in any modern state, whether civilized, barbarian, or savage. These are human suggestibility, reasoning by analogy, reversion to primitive modes of reasoning (mostly included in the former), the assumption that ideal associations have corresponding material connections, and morbid imagination. Of these, suggestion, reasoning by analogy, and morbid imagination are the most important and fundamental.

Human suggestibility, in some degree at least, is immeasurable. Dubois has made the computation that only three per cent. of the human race is free from the slavery of suggestion. How he arrives at these figures we do not profess to comprehend, but the fact will not be gainsaid that the proportion of the unsuggestible is very small. So soon as one leaves the cold ground of mathematical reasoning, difficulties are met with in resisting the emotional elements of suggestibility, and the credulity of the multitude finds its gratification in this very element of human suggestibility. Taking it into consideration, the charlatan thrives through unworthy motives; the true physician must utilize the same power, but his aim should be and has been to educate his oversuggestible patients to a healthier philosophy of living in the battle with the discords and discomforts of life as they find it.

The omens and signs that sway people's minds are relics of old usages, customs, and manners. They derive their power from the inveterate habit of the uneducated of reasoning too much by analogy. The modern German peasant who says that meeting a flock of sheep is lucky, but encountering a herd of swine unlucky, and the Cornish miner who turns aside in horror on meeting a rabbit or an old woman on his way to the pit's mouth, is no more illogical than the modern lady of culture and even a college education who argues the good in Christian Science on the analogy of certain cures of incurable disorders. They both exhibit the radical defect of logic, of reasoning too strictly by analogy, and are keeping up relics of primitive types of thought.

And so with the factor of morbid imagination in fostering belief in the myths of ancient times. Viewed from the strictly anthropomorphic point of view, personal will entered into the day and the night, into the waterfall and into the whirlpool. Clouds were the great cows of the sky, with full udders milked by the winds; thunder was the roar of the wild beast; lightning was the serpent darting at its prey; zoster was the snake wound round the body of its victims, and even in the highest of cultures these anthropomorphic conceptions through much reduced, still held sway over the vast number of minds. We have been able to touch only upon

certain features of Dr. Shute's paper, but are tempted to point out some of his conclusions, which, although briefly stated, are of great interest.

How can the public be safeguarded against evil suggestions in medicine, against too much reasoning by analogy about medical subjects in normal modern times, and against reversions to primitive methods of philosophizing when dealing with accident and disease? It is admitted that mental atavism must be met with just as is physical atavism, and that no justifiable faith in the future will preclude this accident. Reasoning by analogy can best be curtailed by education; not by book reading necessarily, but by fostering a spirit of rational skepticism concerning extravagant and improbable pretensions in medical affairs, especially as expounded in secular publications.

#### HYGIENIC FADS.

Though it is for the most part the fate of our domestic animals to come to a violent end, they are not troubled with forebodings of death, and it may be questioned whether, on the whole, they are not happier than man. Some of them are condemned to grievous toil, but in general they are well housed and well fed, and theirs is not the burden of anxiety. Their condition, in short, must be delightful in comparison with that of the man who is incessantly taking thought of his health and of the prolongation of his life. We all know that the number of such men is very great, and it seems to be continually on the increase. It really looks as if a large proportion of the civilized men and women of the world were allowing themselves to be transformed into hypochondriacs.

Many are the men who wear out a hand mirror in inspecting their tongue, who examine their pulse almost hourly, who take their temperature every day, and who fret about a little increase of girth. They are in a perpetual state of fidgets about their health, and their solicitude is fed by what they read in the newspapers and on the display signs with which the public conveyances are adorned, so many philanthropists are there who are ready to interpret every little irregularity of their bodily condition and put them on the high road to health and longevity. There are the numerous cereals, each of which is heralded as the one article needed to insure good digestion; there are the multifarious machines for taking the place of regular exercise; there are mysterious agencies for augmenting vitality; there are "chest protectors" and articles of apparel that one cannot do without if he would preserve his health; and there is the endless list of drugs to supplement all such appliances if not to supplant them.

Learned men there are in abundance, or men as-

suming to be learned—wise, too, above the ordinary—who write books and magazine articles setting forth the minutiae of the art of prolonging life. They are clever apostles of the plausible, and they have reduced the whole range of hygiene to a faultless system—

Till you ask with surprise why anyone dies,  
And what's the disorder that kills, my boy.

They prate of proteids and other things mystifying enough to be impressive, and they all join in the chorus "We eat too much." Many of them are champions of the "hardening" process. They tell us of lurking poisons to avoid as one would shun the wiles of Satan. A slight drawback to the amount of good that they might accomplish springs from the fact that they do not all agree, and meantime there are some of us who are rash enough to go on under the more or less complete guidance of inclination, which in the happy brutes generally answers the purpose.

#### TYPHOID FEVER TRANSMISSIBLE IN THE STAGE OF INCUBATION.

We have learned that the subjects of typhoid fever continue to excrete the germ of the disease for a long time after the actual illness has ceased. Such prolonged excretion adds materially to the difficulty of checking the spread of the infection. An additional difficulty will be encountered if certain observations reported by Dr. H. Conradi (*Deutsche medicinische Wochenschrift*, October 10, 1907; *Semaine médicale*, January 22, 1908) are confirmed. These observations are not only Conradi's own, but also those of von Drigalski, G. Mayer, Pietz, and Prigge. They find that typhoid bacilli are eliminated in the feces and urine of persons who are still apparently in perfect health and do not come down with the disease for so long a period, sometimes, as three weeks.

In an instance that came under Conradi's notice Eberth's bacillus was found in the blood of a boy, twelve years old, whose sister lay ill of typhoid fever. The girl was taken sick early in March, and on the 24th of that month, while the boy was still well, the author obtained pure cultures from his blood. Four days later the boy showed symptoms of the disease. Therefore, says Conradi, bacilli that have been swallowed are capable of multiplying and even penetrating into the circulation while yet the infection is latent, and at that period there is danger to those who are associated with the person that is about to become ill. Epidemiological observations, says the author, sustain this view, and he has recently reported three cases of the spread of infection during the period of incubation.

Evidently, then, it is not the excreta of the sick

alone that may disseminate typhoid fever, but also those of persons who, though they have been exposed to the disease, have not yet shown symptoms of it. They must all be watched, and measures should be taken to prevent their contaminating the drinking water and other articles that may be ingested by others. It will be seen that this task sensibly augments the sanitary work necessary in connection with typhoid fever. Inasmuch as individuals in the stage of incubation may still be engaged actively in their ordinary vocations and traveling perhaps for considerable distances, often into districts where they are not likely to be suspected of harboring infectious material, the difficulty of dealing with them in such a manner as to prevent their spreading the disease will at once be recognized.

#### OSZENA DERIVED FROM THE DOG.

In *La Clinique* for February 14th we are reminded by a note signed by Dr. Georges Laurens that last year, in the *Annales des maladies de l'oreille*, Dr. Perez, of Buenos Aires, expressed the opinion that ozæna, declared by Löwenberg twenty-five years ago to be contagious, might be contracted from the dog. It seems that Perez had met with twenty cases in which the disease was probably of canine origin, and he states that Löwenberg's bacillus is found in the dog, though he does not inform us that actual ozæna is observed in that animal. In view of its refractory and repulsive character, all possible pains ought to be taken to avoid ozæna, among them avoidance of the disgusting habit of allowing a dog to lick one's face. The practice is known to be dangerous in other directions than that of the risk of contracting ozæna; for example, it plays a prominent part in the conveyance of hydatid disease. Oftener than is generally supposed, the fondling of pet animals leads to infection, and it is one of the manifestations of good will toward them that should be exercised only with the greatest caution.

#### WHITE PRECIPITATE OINTMENT.

It would seem from inquiries that have lately come to our knowledge that the newer graduates of pharmacy leave school without that drilling in the smaller details of dispensing that distinguished the pharmacists of an older generation. A touchstone of the care observed by a pharmacist in the preparation of galenic compounds is the white precipitate ointment of the pharmacopœia, officially entitled *unguentum hydrargyri ammoniaci*. As prepared by different pharmacists this ointment presents varieties of appearance and consistence

and one is often tempted to ask under which standard New York pharmacists prepare the official drugs and medicines. Of course, when white precipitate ointment is asked for or prescribed, only the unguent of the pharmacopœia should be dispensed. This is a preparation consisting of equal parts of hydrous wool fat and white petrolatum medicated with ten per cent. of ammoniated mercury. Explicit directions are given in the pharmacopœia for the compounding of the ointment so as to provide a smooth, creamy salve in which the ammoniated mercury is so evenly distributed as to make the particles invisible to the naked eye. Since the eighth revision of the pharmacopœia became official we have been supplied with what was represented to be ointment of ammoniated mercury, which consisted of a coarse mixture of gritty lumps of ammoniated mercury and yellow petrolatum, and with mixtures of lard and ammoniated mercury, which in all cases showed a lack of care in preparation that was most reprehensible. Pharmacists who would be so indifferent to the requirements of the pharmacopœia would not think of the necessity of using a horn or vulcanite spatula in the preparation of a mercurial ointment, and one is justified in assuming that carelessness in one thing means carelessness in others. It is a disturbing thought for a physician, who is often compelled to depend on the professional honor of the pharmacist for the preparation of medicines in strict accordance with the rules of the apothecary's art. The ointment of ammoniated mercury is frequently prescribed in the treatment of the slight eczematous conditions which sometimes make their appearance on the margins of the eyelids in young children, as well as in adults, but good results cannot be expected with ointments which are hastily thrown together without regard to the elementary principles of pharmaceutical technique.

#### "AEROSTATHERAPY."

An enumeration of the therapeutic agencies which have been advanced for the cure of pulmonary tuberculosis would disclose a most varied series of remedial measures. Not the least novel of the list would be the suggestion recently made before the Académie des sciences by M. Christian Beck (*Bulletin médical*, 1907, p. 1054) that sanatoria be provided with tethered balloons, in which patients may be elevated to any heights desired. The arguments for such a procedure certainly have some basis in fact, for, as Beck points out, the chemical and biological purity of the air encountered at a height is far greater than can be obtained closer to the earth; the

dampness so often met with at terrestrial resorts of great altitude may be avoided, and the ascent may be varied to meet the indications for each patient. He further states that the variation in the atmospheric conditions obtained by returning to the earth each night is of actual benefit to the tuberculous patient. Of this we have some doubt. It hardly seems credible that a condition so foreign to man's normal environment and so abrupt in its application can be anything but harmful to an organism already rendered unstable by the toxins of tuberculous disease. It seems probable that M. Beck's suggestion is destined to a place among the "fads and fancies" of therapy.

### Obituary.

FRIEDRICH VON ESMARCH, M. D.,  
of Kiel, Germany,

In Kiel there recently died the well known German surgeon Friedrich von Esmarch. Born January 9, 1823, in Tönning, Schleswig-Holstein, he received his medical education at the universities of Kiel and Göttingen, and took his degree in 1848, having been assistant to von Langenbeck since 1846. In the war of independence of Schleswig-Holstein he took part, first as a line officer, later as surgeon, and was, in 1849, admitted as Privat-docent to the medical faculty of Kiel, where he in 1854 became director of the surgical clinic and three years later professor of surgery and director of the hospital. This position he held until his resignation in 1899. Von Esmarch took part in the Prussian wars of 1864, 1866, and 1870-'71. In the war against Denmark he served with the army as surgeon; in the war against Austria he acted as general superintendent of the hospitals in Berlin; and during the Franco-Prussian war he filled the office of general surgeon.

Von Esmarch's scientific researches were especially directed to military surgery, to which branch he made many valuable contributions. But he is best known as the author of Esmarch's band, a description of which he made public for the first time in 1873 at the congress of the German Surgical Society (Volkman's *Sammlung Klinischer Vorträge*, No. 58).

His son by his first marriage is Edwin von Esmarch, since 1899 professor of hygiene in the University of Göttingen. In 1872 von Esmarch married Henriette, princess of Schleswig-Holstein-Sonderburg-Augustenburg, aunt of the present Emperor of Germany. In 1887 he was knighted, and in 1899 he occupied the title of *Baron*.

### News Items.

**Changes of Address.**—Dr. Ralph Francis Ward, to 205 West One Hundred and First street, New York.

**University of Michigan.**—A chapter of the honorary fraternity Alpha Omega Alpha has just been established in this university.

**A New Psychoneurological Institute** was recently opened in St. Petersburg. It is under the direction of Professor Bechterev.

**The Tristate Medical Society**, of Virginia and the Carolinas, held its tenth annual meeting in Charlotte, N. C., on February 18th and 19th.

**Iowa State Board of Health.**—Governor Cummins has appointed Dr. Albert De Bey, of Orange City, Sioux County, to membership on the board, to succeed Dr. F. W. Powers, of Waterloo, who retired from office on February 1st.

**Philadelphia County Medical Society.**—At a special election, which was held on February 12th to fill vacancies due to resignation, Dr. Jay F. Schamberg was elected fifth vice president, and Dr. S. W. Gadd, sixth vice president of this society.

**A Contribution to the Robert Koch Institute Fund.**—It is reported that Mr. Andrew Carnegie has contributed \$100,000 to the fund for the founding of an institute in honor of Dr. Robert Koch, to be devoted to research work in tuberculosis.

**The Philadelphia College of Pharmacy** held a pharmaceutical meeting on Tuesday evening, February 18th. Dr. Anna S. Kugler, a medical missionary from India, addressed the meeting. Her subject was *The Native Practice of Medicine and Pharmacy in India*.

**Buffalo Academy of Medicine.**—The regular meeting of the Section in Obstetrics and Gynecology was held on Tuesday evening, February 25th. The programme included a paper by Dr. Sigmond Goldberg on *The Danger of Operating in Acute Pelvic Conditions*.

**A Hospital for Consumptives at Albuquerque.**—It is reported that the Presbyterian Church of the United States will build in Albuquerque, New Mexico, a large hospital for the treatment of consumption, at a cost of about \$1,000,000. Albuquerque has donated the site for the institution.

**The Floyd County, Ga., Medical Society** held its regular monthly meeting in Rome on Saturday, February 22d. Papers were read by Dr. James P. Ballenger, of Crystal Springs, and Dr. W. L. Funkhouser, of Rome, the subject of Dr. Funkhouser's paper being *Medical Ethics*.

**Contagious Disease in Chicago.**—The Bureau of Contagious Diseases received notification of 470 cases of communicable diseases during the week ending February 15, 1908, which was an increase of seventeen over the previous week, but twenty-seven less than the corresponding week in 1907.

**The Medical Alumni of the University of Pennsylvania** held their annual banquet at the Bellevue-Stratford Hotel on Thursday evening, February 20th. Dr. George A. Piersol acted as toastmaster. Dr. S. Weir Mitchell, Dr. Barton Cooke Hirst, and Dr. Charles L. Dana responded to toasts.

**White River, Vt., Medical Association.**—A regular meeting of this association will be held at White River Junction on Wednesday, March 4th, at 1:30 o'clock. The programme will include an address on the Use of the Biograph in Epilepsy, by Dr. Walker G. Chase, of Boston. The lecture will be illustrated with biograph pictures.

**University of Wisconsin.**—Dr. Arthur S. Loewenhardt, of Johns Hopkins University, has been appointed professor of pharmacology and toxicology at the recently established college of medicine at the University of Wisconsin, and Dr. Charles H. Bunting, of the University of Virginia, has been appointed to the chair of pathology.

**Personal.**—Dr. Robert Koch expects to visit the United States some time this spring. It is his intention to take a rest for a year, and consequently has refused all invitations to lecture while here.

Dr. C. M. Pearce, of Sumpter, Ore., is registered at the Philadelphia Polyclinic and College for Graduates in Medicine.

**New Buildings for State Institutions in Minnesota.**—Contracts have been awarded by the Minnesota State Board of Control for the following new buildings for State Institutions: An addition to the main building of the Rochester State Hospital, to be known as Ward C; a contagious hospital building at the Fergus Falls State Hospital; and a tuberculosis hospital building at the St. Peter's State Hospital.

**Medical Inspection of Schools in Chicago.**—During the week ending February 15, 1908, the medical inspectors of schools examined 7,166 school children, excluding 233 from attendance. Twenty-five were excluded because of measles, 10 for scarlet fever, 26 for chickenpox, 7 for mumps, 1 for tuberculosis, 2 for diphtheria, and 2 for whooping cough.

**Richmond, Va., Academy of Medicine and Surgery.**—A regular meeting of this academy was held on Tuesday evening, February 25th. Dr. F. M. Reade read a paper on the Therapeutics of the Salts of Salicylic Acid, which was discussed by Dr. William S. Gordon, and a paper on the Sequelæ of Gripe was read by Dr. T. A. Parker and discussed by Dr. M. D. Hoge, Jr.

**Ventilation of the New York Subway.**—A bill has been introduced in the Legislature by Assemblyman Egleton which will give the Board of Health of New York City authority to compel a proper ventilation of the subway. The bill empowers the board to prescribe rules and provides for a penalty of \$250 a day for neglect to comply with the orders of the board.

**The Triprofessional Medical Society of New York** held a stated meeting on Tuesday evening, February 25th. Dr. Ferdinand C. Valette read a paper on the Treatment of Chronic Gonorrhœa, which was discussed by Dr. Boleslaw Lapowski, Dr. Ramon Guiteras, Dr. George K. Swinburne, Dr. G. Morgan Muren, and others. Dr. Charles E. Panoff read a paper on Epididymitis with a New Supporting Dressing, which was followed by a general discussion.

**The Mortality of Baltimore.**—The report of the Department of Health shows that during the week ending February 22, 1908, there were 204 deaths from all causes, as compared with 211 for the corresponding week in 1907. The principal causes of death were: Typhoid fever, 1; scarlet fever, 3; whooping cough, 1; influenza, 3; consumption, 24; apoplexy, 8; pneumonia, 27; organic heart diseases, 13; Bright's disease, 18; congenital debility, 14; old age, 8; accidents, etc., 11.

**The Medical Society of the District of Columbia** held a meeting on Wednesday evening, February 19th. The general topic for discussion was Typhoid Fever, its Causes and Prevention. Dr. G. Lloyd Magruder read a paper reviewing the various campaigns against typhoid fever and the work that had been accomplished by the milk commission. Among those who took part in the discussion were Dr. H. W. Wiley, Dr. M. J. Rosenau, Dr. B. M. Bolton, Dr. Sternberg, Dr. Woodward, Dr. Kober, and Professor C. E. Lane.

**The Pathological Society of Philadelphia** held a stated meeting on Thursday, February 27th. Dr. W. M. L. Coplin read a paper entitled Further Remarks on the Bundle of His, Studied Immediately after Death. Dr. Howard T. Karsner read a paper on Whole and Differential Leucocyte Counts Before and After Anesthetic Administration. Dr. George Foster read, by invitation, a paper entitled A Study of the Hemorrhagic Diathesis in Leukæmia and Erythræmia. A number of short communications were also read.

**The Manhattan Medical Society** held a stated meeting on Friday evening, February 28th. The program consisted of the report of a case of Acute Cholecystitis by Dr. F. L. Cullen, a paper on A Case of Intestinal Obstruction of the Intermittent and Abusive Treatment, by Dr. William C. Brown, and a paper on The True Value of Cambridge's Reaction in the Recognition of Pancreatic Disease, by Dr. Herman Stern. After the reading of papers, a clinical conference was held on the following subjects: Histology, etc.

**A New Anticocaine Measure for Massachusetts** has been proposed by the State Board of Health. The board has appointed a committee to study the question of the use of cocaine in the treatment of the nose. Dr. H. W. Wiley, Dr. M. J. Rosenau, Dr. B. M. Bolton, Dr. Sternberg, Dr. Woodward, Dr. Kober, and Professor C. E. Lane.

he had had numerous complaints from all quarters regarding the illicit sale of cocaine, and that the enactment of some very stringent restrictive legislation was necessary to protect the public. He said that the cocaine was sold mainly in the form of catarrh powders.

**The Maine Association for the Study and Prevention of Tuberculosis**, which has for its object investigation into the prevalence of tuberculosis in the State of Maine, and the dissemination of knowledge concerning the causes, treatment, and prevention of the disease, has just been organized. The officers of the association are as follows: President, Dr. Stephen H. Weeks; first vice president, Dr. Seth C. Gordon; second vice president, Mr. Adam P. Leighton; secretary, Mr. Nathan Clifford; treasurer, Dr. Irving E. Kimball.

**The Mortality of Chicago.**—According to the report of the Department of Health for the week ending February 15, 1908, there were during the week 699 deaths from all causes, as compared with 698 for the corresponding week in 1907. The annual death rate was 16.83 in 1,000 of population. The principal causes of death were: Apoplexy, 15; Bright's disease, 42; bronchitis, 25; consumption, 66; cancer, 24; convulsions, 2; diphtheria, 11; heart diseases, 48; influenza, 27; intestinal diseases, acute, 13; measles, 4; nervous diseases, 22; pneumonia, 144; scarlet fever, 12; suicide, 14; typhoid fever, 5; violence, other than suicide, 28; whooping cough, 4; all other causes, 163.

**Changes in the Bureau of Health of Philadelphia.**—Dr. Seth M. Brumm has been appointed assistant medical inspector, Dr. J. Earl Ash has been appointed first assistant resident physician, Dr. Edward T. Clement has been appointed second assistant resident physician, and Dr. John T. Adlyote has been appointed third assistant resident physician at the Municipal Hospital. Dr. J. Roy McKnight and Dr. Charles J. Swalm have been appointed resident physicians at the Municipal Hospital. Dr. Henry D. Jump has been appointed registrar at the Philadelphia Hospital. Dr. Charles S. Potts has been made a member of the advisory board of the Philadelphia Hospital, Department for the Insane.

**Rochester, N. Y., Academy of Medicine.**—The regular meeting of the Section in Public Health, which includes hygiene, climatology, physiology, pathology, bacteriology, and forensic medicine, was held on Wednesday, February 26th. The programme for the evening consisted of a symposium on The Systematic Examination and Treatment of Children at First Principle in Maintaining a High Standard of Public Health and Efficiency. Dr. Albert C. Snell read a paper on Ocular Defects, and Dr. Nathan Davis McDowell read a paper which dealt with Ear, Nose, and Throat Defects. Dr. S. H. Rosenthal read a paper on General Functional and Physical Defects, and Dr. George W. Goler delivered an address on School Inspection.

**A Fellowship in Pathology at Mount Sinai Hospital.**—It is announced that the George Blumenthal, Jr., Fellowship in Pathology has been established at Mount Sinai Hospital, New York. The object of the fellowship is to aid those who are anxious to obtain a laboratory training and to further the scientific work of Mount Sinai Hospital, the work under the fellowship being carried on in the hospital or elsewhere under the direction of the pathologist. All graduates in medicine are eligible. The stipend is \$500 per annum, the term is one year, and the fellowship cannot be held more than twice by the same person. Applications should be sent to Dr. F. S. Mandlebaum, pathologist, Mount Sinai Hospital, New York.

**Medical Association of the Greater City of New York.**—A general meeting of this association was held at the Imperial, 360 Fulton street, Brooklyn, on Monday, March 2d, at 8:30 p. m., under the direction of the association for the year 1908. Dr. J. Van Gieson will read a paper on the Comparative Therapeutic Value of the Compounds of Iron, which will be followed by Dr. K. A. Wiley, Dr. W. W. Dr. William C. Brown, Dr. H. W. Wiley, Dr. M. J. Rosenau, Dr. B. M. Bolton, Dr. Sternberg, Dr. Woodward, Dr. Kober, and Professor C. E. Lane. Dr. H. W. Wiley, Dr. M. J. Rosenau, Dr. B. M. Bolton, Dr. Sternberg, Dr. Woodward, Dr. Kober, and Professor C. E. Lane.

**Barnes University Merged in the Missouri State University.**—Deeds have been filed by the trustees of Barnes University, St. Louis, conveying the buildings and grounds of that institution, at Garrison and Lawton avenues, to the Missouri State University. The Centenary Hospital has already been transferred to the State. The property is valued at \$250,000 and is free from debt. It is understood that the medical department of the State University will be transferred from Columbia to St. Louis and will occupy the buildings of the Barnes University. The selection of the faculty for the enlarged institution is entirely in the hands of the board of trustees of the State University. It is reported that the medical faculty will be increased from forty-two to ninety members.

**Cornell University Hospital for Cats and Dogs.**—This new institution, which is situated in East Twenty-sixth street, is an absolutely free hospital and dispensary for the treatment of the diseases and injuries of pet animals. The hospital has three floors, and is provided with reception rooms, isolation wards for contagious cases, a general ward, a kitchen, a bathroom, and a large well lighted operating room, equipped with the latest devices in sterilizing apparatus and surgical instruments. Dr. Frederick Gwyer, professor of operative surgery in Cornell University Medical College, is at the head of the hospital staff, and associated with him, as principal assistant, is Dr. Thomas C. Sherwood, a member of the Royal College of Veterinary Surgeons.

**Medical Society of the County of Ulster, N. Y.**—The February meeting of this society was held in Kingston on Saturday evening, February 15th. Dr. Frederick C. Curtis, of Albany, delivered an address on the Diagnosis of Smallpox, which was illustrated by lantern slides. Dr. H. D. Pease, director of the State Hygienic Laboratory, delivered a lecture on Vaccines and Vaccination, which he illustrated by means of lantern slides. Dr. Joseph D. Craig, health officer of Albany, spoke on the subject of the Management of Smallpox Outbreaks. The officers of the society are as follows: President, Dr. Aden C. Gates, of Kingston; vice president, Dr. Thomas Keator, of Accord; secretary, Dr. Mary Gage-Day, of Kingston; and treasurer, Dr. Elbert H. Loughran, of Kingston.

**Scientific Society Meetings in Philadelphia for the Week Ending, March 7, 1908.**—*Monday, March 2d,* Philadelphia Academy of Surgery; Biological and Microscopical Section, Academy of Natural Sciences; West Philadelphia Medical Association; Northwestern Medical Society. *Tuesday, March 3d,* Academy of Natural Sciences; Philadelphia Medical Examiners' Association. *Wednesday, March 4th,* College of Physicians; Association of Clinical Assistants of Wills Hospital. *Thursday, March 5th,* Obstetrical Society; Medical Society of the Southern Dispensary; Section Meeting, Franklin Institute; Germantown Branch, Philadelphia County Medical Society. *Friday, March 6th,* American Philosophical Society; Kensington Branch, Philadelphia County Medical Society.

#### Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Department of Health for the following statement of new cases and deaths reported for the two weeks ending February 22, 1908:

	Children		Adults	
	Cases	Deaths	Cases	Deaths
Typhoid fever	210	7	75	11
Dysentery	21	0	10	0
Scarlet fever	4	0	1	0
Measles	113	0	18	0
Smallpox	4	0	0	0
Typhoid fever	26	5	33	4

#### Lectures at the New York Skin and Cancer Hospital.

—It is announced by the governors of the New York Skin and Cancer Hospital, Second avenue and Nineteenth street, that a series of lectures, which will be free to the medical profession, will be given in the out patient hall of the hospital. The first lecture will be given on Wednesday afternoon until April 15th Dr. Bulkley will deliver a clinical

lecture on diseases of the skin. On April 22d Dr. William Seaman Bainbridge will deliver an address on the Treatment of Unremovable Cancer, with exhibition of cases.

**Charitable Bequests.**—By the will of Loyal L. Smith the Champlain Valley Hospital, Plattsburg, N. Y., receives \$225,000.

By the will of Mrs. Amy Richmond Sheldon the Newport, R. I., Hospital receives \$5,000.

By the will of Levi Schilling the Mount Zion Hospital, San Francisco, Cal., receives \$5,000.

By the will of Mrs. Charlotte Budde, Cincinnati, Ohio, the German Deaconess Hospital receives \$200 and St. Mary's Hospital \$100.

By the will of Mrs. Caroline B. Sears the Industrial School for Crippled Children, Boston, will receive \$1,000; \$200,000 will be divided among various institutions which are to be selected, and the Boston Lying-In Hospital will receive \$80,000. All of these bequests are conditional on the death of the husband without issue surviving.

**A New Chemistry Building for the University of Michigan.**—At the January meeting of the Board of Regents of the University of Michigan, architects were authorized to draw up plans and specifications for a new chemistry building, which will include two large laboratories for general chemistry, two large laboratories for qualitative analysis, one for advanced general chemistry, one for beginning quantitative analysis, one for advanced quantitative analysis, one for beginning organic chemistry, and one for pharmaceutical chemistry, with smaller laboratories for advanced and special work, and private laboratories for the instructing staff. In addition to the laboratories there will be one large lecture amphitheatre and three smaller ones. The total cost will be about \$275,000, and it is hoped that the building will be completed by October 1, 1909.

**The Health of Philadelphia.**—During the week ending February 1, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Typhoid fever, 142 cases, 16 deaths; scarlet fever, 63 cases, 3 deaths; chickenpox, 29 cases, 0 deaths; diphtheria, 76 cases, 13 deaths; cerebrospinal meningitis, 2 cases, 0 deaths; measles, 142 cases, 3 deaths; whooping cough, 31 cases, 3 deaths; pulmonary tuberculosis, 121 cases, 62 deaths; pneumonia, 99 cases, 71 deaths; erysipelas, 13 cases, 5 deaths; puerperal fever, 4 cases, 3 deaths; mumps, 19 cases, 0 deaths; cancer, 17 cases, 26 deaths; tetanus, 1 case, 0 deaths. The following deaths were reported from other transmissible diseases: Tuberculosis, other than tuberculosis of the lungs, 7; diarrhoea and enteritis, under two years of age, 9. The total deaths numbered 542 in an estimated population of 1,532,738, corresponding to an annual death rate of 18.31 in 1,000 of population. The total infant mortality was 116; under one year of age, 94; between one and two years of age, 22. There were 41 still births—22 males and 19 females.

#### Society Meetings for the Coming Week:

**MONDAY, March 2d.**—German Medical Society of the City of New York; Utica, N. Y., Medical Library Association; Niagara Falls, N. Y., Academy of Medicine; Practitioners' Club, Newark, N. J.; Hartford, Conn., Medical Society.

**TUESDAY, March 3d.**—New York Academy of Medicine (Section in Dermatology); New York Neurological Society; Buffalo Academy of Medicine (Section in Surgery); Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Hudson County, N. J., Medical Association (Jersey City); Medical Association of Troy and Vicinity; Hornellsville, N. Y., Medical and Surgical Association; Long Island, N. Y., Medical Society; Bridgeport, Conn., Medical Association.

**WEDNESDAY, March 4th.**—Society of Alumni of Bellevue Hospital; Harlem Medical Association, New York; Elmira, N. Y., Academy of Medicine; Psychiatric Society of New York.

**THURSDAY, March 5th.**—New York Academy of Medicine; Dansville, N. Y., Medical Association.

**FRIDAY, March 6th.**—New York Academy of Medicine (Section in Surgery); New York Microscopical Society; Gynecological Society, Brooklyn, N. Y.; Manhattan Clinical Society, New York; Practitioners' Society of New York.

1. Pendulum Apparatus and an Apparatus for Rotary Correction in Curvature of the Spine,  
By ROBERT SOUTTER.
2. Mathapan Day Lamp,  
By DAVID TOWNSEND.
3. A Diabetic Chart,  
By ELLIOTT P. JOSLIN and HARRY W. GOODALL.
4. The Best Things in Therapeutics,  
By GUSTAVUS ELIOT.
5. Kallak; an Endemic Pustular Dermatitis,  
By JOHN M. LITTLE.

#### 1. Pendulum Apparatus and an Apparatus for Rotary Correction in Curvature of the Spine.—

Soutter describes two such apparatus; the first one he has used for five years, and is adapted to increasing the flexibility of the spine laterally at any level by the pendulum motion of the lower spine, while the upper is held stationary, or of the upper spine while the lower is held stationary. The amount of motion can be limited by weights, and the amount of force to obtain flexibility can be lessened or increased. This apparatus consists of a rectangular frame swung at the middle, inside of which are two half frames, one swinging above and the other below, from a point at the middle of the first frame. The first frame can be allowed to swing while the lower inside frame is made stationary, or the first frame may be fastened and the lower half frame allowed to swing. In this way the upper segment can swing and the lower remain stationary or *vice versa*. The upper half frame is used in connection with the large or lower half frame or for the application of pressure pads or straps. It can be placed in any position desired, and pressure pads and rests can be applied at any level to localize or limit the motion. It is useful in cases with bony changes, as well as in cases where the deformity is limited to the soft parts. In simple curves and round shoulders it has been extremely satisfactory. In curvature of the spine a twist or rotation is almost always present in all cases to a more or less degree. In advanced cases the twist is very marked, and in a compound curve it may be on both sides of the spine at the convexity of each curve. The application of side pressure to correct the curvature, if not carefully applied, will often increase the rotation. This apparatus has been devised so that the amount of rotation of the spine may be increased or diminished to the right or to the left and at the desired level. Both pressure correction and active or passive rotary movement can be utilized in the treatment. This can be done with the shoulders level, inclined, displaced laterally, or with the pelvis tilted at any angle so that the patient may be placed in as advantageous a position as possible and the corrective stretching applied. The patient is placed in position and immobilized up to the point where the twist is desired. The twist may be limited to the right or to the left, or the amount of rotation limited in either direction. By a rotary motion the lumbar space can be treated, and the muscles going to the lumbar region strengthened or stretched. The second apparatus consists of a base and a flexible inclined

which twists on the base. The motion is regulated by weights and pulleys attached to the arms. The base is narrower towards the front and broader towards the back to allow for the rotation of the arms. The seat teeters on a pivot until the side of the rectangular frame touches the side of the upper half frame. Blocks keep the rectangular frame steady when the rotary motion is being used. Should it be advisable to increase flexibility to one side, one block only may be inserted. Should resistance to lateral motion be needed in order to increase the muscular work, weights are attached to hooks below the seat of the rectangular frame.

4. The Best Things in Therapeutics.—Eliot gives the following drugs as of greatest value, both to the practitioner and to the patient: 1, Mercury in syphilis; 2, the salicylates in rheumatism; 3, quinine in malarial affections; 4, antitoxine serum in diphtheria; 5, aconite in the fever of acute diseases; 6, digitalis in chronic heart disease; 7, alcohol in cardiac weakness of acute disease; 8, ergot in uterine and pulmonary hæmorrhage; 9, creosote in diseases of the respiratory organs; and 10, the bromides in nervousness.

5. Kallak.—Little describes a very frequent skin disease, endemic pustular dermatitis, so prevalent among the Eskimos, and which was seen at the Moravian mission stations at Makkovic, Hopedale, Nain, Okak, and Ramah on the East Labrador coast, and at Killinek, Ungava Bay. When the Moravians translated the Bible into the Eskimo language, they had great difficulty in finding equivalents for many words. Leprosy was one of these. They had to find some word which would be understood by the Eskimo to represent a contagious, disfiguring, chronic disease, and they chose the word kallak, which was the Eskimo word for the disease described by Little. Broadly translated, it means skin disease. The missionaries thought this disease was scabies, so that to-day in the Eskimo-English-German dictionary Kallak equals Leprosy, scabies, skin disease, but as ordinarily used, it means the one definite thing, the pustular dermatitis, so common among, and peculiar to, the Eskimo. It is not a disease caused by dirt, but it is peculiar to the Eskimo, and never appears in the foreigner. The main symptom is the itching, and it appears as an eruption in the dorsal surfaces of the hands and feet, and the upper and under surfaces of the fingers and toes. At first vesicular, it almost immediately becomes pustular. In fact, the vesicular stage is seldom seen. The pustules, of various sizes from a pin head to a ten cent piece, are not surrounded by the inflammatory zone which one would expect. With the appearance of the eruption, the feelings of malaise disappear, which preceded the period of eruption, but intense itching supervenes. The pustules then appear in different groups in order, on the elbows, arms, and hands. From these centres it spreads. This spreading is independent of scratching, and takes place when the part is carefully protected and treated with antiseptics. Generally, however, the scratching and rubbing soothe or soothes a generalized itching. The eruption is limited, bleeding takes place, crabs and scabs appear. It is however, usually cured by eruption, and never becomes

Its course is very protracted, and thickening and discoloration of the skin appear. The disease may disappear, only to break out again on cessation of treatment. There is no inflammatory area around the lesions, and they are not painful except upon the buttock, and where a secondary infection has taken place. Whole houses, and even communities of Eskimos are affected at a time. The only facts that seem to have a bearing etiologically are that while it may occur at any time of the year, if they have plenty of seal flesh to eat they do not have kallak. Most of the cases, as well as the worst cases, and the epidemics, occur in the autumn after they have been living almost exclusively on a fish diet, and especially after a failure of the berry crops. No special microorganism is found in connection with the eruption, nor does it act like an autoinoculative process, such as impetigo contagiosa. The author believes it to be a symptomatic reaction to some toxine elaborated on account of the Eskimo diet, perhaps influenced by his known susceptibility to suppurative and epidemics of all kinds. As to treatment, the Eskimos themselves were accustomed to apply seal oil on rags without much effect. Dr. Hutton has found the best treatment to be the addition of seal meat and berries to the diet, the application of protective dressings, with a lotion of lead subacetate, one part in 300, and on adults in the later stages an ointment of zinc oxide and tar.

1. Operative Treatment of Cancer of the Rectum,  
By EDWARD ARCHIBALD.
  2. The Magnesite Splint. A New Surgical Dressing,  
By RAYMOND RUSS.
  3. The Value of an Absolutely Vegetarian Diet in Psoriasis,  
By L. DUNCAN BUCKLEY.
  4. Atypical Typhoid Fever; Its Part in Preventive Medicine, and Its Distinctive Diagnosis from Estivo-autumnal Malaria,  
By JOHN PELHAM BATES.
  5. Observations on the Failure of the Radial Pulse When the Arms Are Elevated,  
By HENRY SEWALL.
  6. Final Results of Conservative Surgery of the Tubes and Ovaries,  
By ABRAM BROTHERS.
  7. Report of One Hundred and Seven Cases of Cancer Treated with Röntgen Ray, with Comments Thereon,  
By ENNON G. WILLIAMS.
3. **The Value of an Absolutely Vegetarian Diet in Psoriasis.**—Buckley has used for a number of years an absolute vegetarian diet, only allowing butter, but not milk, as treatment for patients suffering with psoriasis. The effect of this cutting off the supply of animal nitrogenous food has been very remarkable and striking in many instances (a considerable amount of nitrogen is still supplied by certain vegetables, as the legumes and oatmeal). Patients continually notice the change in the color and character of the eruption, it paling and becoming less scaly, and even entirely disappearing in some weeks, with absolutely no local treatment. In a number of instances this diet has been given to patients who had long been under his care, even for years previously, and thus they were well able to judge of the result of this radical change in the mode of life, and have watched with great interest the often rapid improvement in the eruption, under precisely the same treatment as before. This treatment has been given to patients at all periods of life, from nine to seventy-

eight years of age, and has been carried out with varying degrees of fidelity. The note has been repeatedly made that when there has been a neglect of the dietary element there has been a recurrence of the eruption, which again yielded rapidly when stringent measures were enforced. On the other hand, there have been a number of patients who have faithfully pursued this plan of treatment, in whom a long existing psoriasis has remained absent, and who, having become accustomed to the diet, say that they have lost the desire for animal food and will not touch it again. In conclusion, the author states that, while he advises an absolutely vegetarian diet in psoriasis, he believes that it has its limitations, and must be directed with care and intelligence; but that in proper cases it can control the eruption and prevent its recurrence. But patients with this eruption at times will require in addition the most varied treatment, internal and external, in order to accomplish the quickest and best results. How internal remedies act can not yet be fully stated, but in the light of our present study they probably have their action in improving the metabolism of nitrogenous substances.

6. **Final Results of Conservative Surgery of the Tubes and Ovaries.**—Brothers describes his personal experience with conservative surgery of the ovaries and tubes. He states that he has had only one death out of 160 such cases. In ovarian surgery cystic ovaries afford an opportunity for conservatism, while ovaries that have undergone fibroid degeneration are seldom amenable to conservative surgery. Ovaries in juxtaposition with pus tubes or purulent pelvic collections can safely be left undisturbed, or may be subjected to partial excision. These ovaries, if not the seat of the abscess at the time of operation, seldom give rise to trouble later. The desirability of applying conservative surgery to pus tubes is open to question in his mind. He is in favor of total and complete ablation of pus tubes down to the horn of the uterus. Experience with secondary operation for infected stumps has driven him to this position. Brothers describes plastic work on the tubes, mentioning also the excision of the tubes for the purpose of inducing sterility, where he has never seen a new connection formed to permit of the union of an ovum with a spermatozoon. Speaking of pelvic peritoneal adhesions with considerable risk of injuring the annexa, tubes, or ovaries in plastic operations, he says it is wiser to proceed with their complete extirpation, as the retention of such mutilated or damaged annexa only too often threatens the ultimate comfort and health of the patient, and leads to secondary operations for their final removal. The author divides his cases in three groups: In group 1 (conservative work in twenty-six patients on the Fallopian tubes) he has noted unsatisfactory results in two cases. One of these patients a year later was suffering from a pelvic inflammatory mass which could be distinctly felt. In the second case the patient required a secondary laparotomy for the removal of an infected stump left after the first operation. One of the patients in this series of cases died suddenly of a cancer of the rectum, which does not reflect on the propriety of the operation previously done by him. In group 2 (conservative work on forty-four patients in the ovaries)

six patients had good reason to complain of postoperative suffering. A distinct pelvic mass was present in one case and a secondary operation was required in another. In group 3 (conservative work in ninety patients with adhesions of tuboovarian disease) he has notes of seven unsatisfactory results. In three cases of this group the patients presented pelvic inflammatory masses, subsequent to operation, which caused much suffering. Four patients required secondary operations. Although the total number of secondary operations done in his cases after conservative surgery amounts to only six cases, he readily concedes that this figure is contestable on the ground that he has lost sight of a certain number of his patients after they left the hospital. Some of these patients possibly required secondary operations elsewhere at some subsequent period. As six patients required secondary operations in the cases which he was able to follow it may be fairly assumed that six others were submitted to similar operations in the other half lost from view. Thus he infers that the maximum necessity for secondary operations after conservative annexal surgery does not exceed 7 per cent. He estimates the postoperative morbidity after conservative surgery of the annexa to be about 23.5 per cent.

#### MEDICAL RECORD.

February 22, 1908.

1. Some Notes on the Ætiology, Prophylaxis, and Therapeutics of Laryngeal Tuberculosis. Including Some Clinical Experiments with Bier's Congestive Hyperemic Treatment,

By S. ADOLPHUS KNOPF and ARTHUR J. HUEY.

2. Urticaria, By EDWARD B. FINCH.

3. Cystitis in Women. With Report of Forty-five Cases. Studied Cystoscopically and Some Modifications of Treatment, By ELLICE McDONALD.

4. The Physical Signs of Incipient Pulmonary Tuberculosis, By ABRIEL ABRAMS.

5. Carcinoma of the Right Nasal Cavity and of the Antrum of Highmore, By LOUIS KLEMPNER.

6. Sudden Death in Pneumonia. Its Cause and Prophylaxis, By W. PARKER WORSTER.

**1. Laryngeal Tuberculosis.**—Knopf and Huey describe Kuhn's lung section mask, based on Bier's original idea of having the patient inhale in a slightly obstructed manner, so as to produce negative pressure in the thoracic cavity. The authors have studied the results produced by this mask. They selected six cases of laryngeal tuberculosis from the various wards in their service at the Riverside Sanatorium. On reexamination after the first application of the mask they noted that a marked congestion was produced in all the mucous membranes of the upper respiratory tract. This was especially noticeable in the membrane of the soft palate and epiglottis due to the usual pale character of the membrane in these parts. The atonic membrane, characteristic of such cases, was covered after treatment with a network of small dilated venules, proving conclusively the utility of the mask to produce the desired venous hyperemia. With this encouraging beginning the masks were worn fifteen minutes three times daily, and examinations made from time to time to discover any change in the pathological condition of the larynx. After a few days the congestion of the membranes became more or less permanent, lasting over from one treatment to another, the mucous membranes losing their

characteristic pallor. The cases ranged from the mildest with only slight infiltration of the cords and arytenoids with impairment of motion to the severest type with extensive ulceration, and in one case perichondritis and external abscess. During the application of the mask very little discomfort was experienced by the patients, consisting of slight dizziness and feeling of oppression. This became less as the patients became accustomed to the treatment. In one case complicated with chronic otitis media with tinnitus, the dizziness became so severe as to interfere with the regularity of the treatment. This was especially true in heavy, stormy weather. During the two months of treatment all the cases but one showed some improvement. In the cases of infiltration without ulceration the improvement was mainly symptomatic, the hoarseness and discomfort being relieved without any noticeable change in pathological lesion. Where ulceration existed the ulcer showed healthier, redder granulations covered by far less secretion than formerly.

**5. Carcinoma of the Right Nasal Cavity and of the Antrum of Highmore.**—Klempner describes such a case. The patient was operated upon by the author according to Denker's method. A horizontal incision in the mucous membrane of the anterior wall of the right superior maxilla was made, beginning half an inch to the left of the frenum above the sockets of the teeth, and enlarged upwards to the apertura pyriformis and outwards to the last tooth. It became evident that destruction had already taken place of the periosteum and bony wall in the fossa canina, the size of a quarter of a dollar, through which opening the tumor was bulging. The soft parts were pushed back upwards to the lowest margin of the orbit and inwards, until the lateral and lower margins of the apertura pyriformis were laid open. The whole anterior wall of the antrum and the growth which filled it were then removed. The interior wall of the antrum was also in great part destroyed by the tumor in the region of the middle turbinated bone. The mucous membrane of the lateral nasal wall was separated from the bone below the inferior turbinated, and the whole interior bony wall of the antrum removed from the apertura pyriformis, as well as the inferior turbinated. Then followed the resection of the middle turbinated, the removal of the tumor masses from the nasal cavity and the nasopharynx, the removal of all the ethmoidal cells, which were almost destroyed by the growth. The frontal and sphenoidal cavities were not affected. The loosened mucous membrane of the lateral wall of the nasal cavity was used to cover the floor of the antrum, and the so formed single big cavity was filled with iodoform gauze. The wound of the mouth was then closed. The after treatment was carried out through the nose. The course after the operation was very satisfactory. The highest temperature was 101°, on the third day. On the fourth day the packing was removed and not renewed; on the sixth day the sinuses were removed, the wound of the mouth healed without complication. After ten days the patient left the hospital. Four months later there was no sign of recurrence.

**6. Sudden Death in Pneumonia.**—Worster discusses cold application in severe cases of influenza.

in pneumonia. He says that the excitation of cold is the most powerful and energetic agent for combating such collapse and can be accomplished in the following manner: A bathtub of water at 100° F. to extend just above the patient's hips is prepared and the patient placed in it or held in a semirecumbent position, and several basins of water at 60° or lower, as the case may indicate, are poured over his shoulders, chest, and back, the operator standing on a chair and holding the water as high as possible so as to get the required force. Such a procedure, if the patient is unconscious or delirious, will often arouse him to consciousness and brighten his eye, and his countenance will wake up from its apathetic appearance, his shallow respiration will become deeper, and the excitation of the cold upon his bronchial tubes will cause him to cough and expectorate and free them from mucus and his air cells from threatened hypostasis, his cyanosed and marble skin will become ruddier, the capillary circulation will be reestablished, and the heart will gain in force and diminish in frequency. This procedure will positively change the whole aspect of the case, and perhaps only one application will suffice to save the life of that patient.

By D. R. PATERSON.

1. **Tubal Gestation.**—Tate states that the group of symptoms which can be described as typical of this complaint are as follows: The patient, who has missed one or two periods, is suddenly seized with severe pain in the lower part of the abdomen, which may be accompanied by some faintness, and is followed by a hæmorrhagic vaginal discharge. The patient probably goes to bed, but, as the pain soon subsides, she may get up in a day or two feeling fairly well. Soon after getting about again she has a second more severe attack of pain, with signs of faintness, and the nature of the case becomes evident. These cases may be divided into two classes: 1. Acute fulminating cases, in which the patient, without any premonitory symptom, is suddenly seized with acute abdominal pain, accompanied by faintness and collapse, together with vomiting. In this class there is a large effusion of blood into the general peritoneal cavity. 2. The more common variety, in which the patient has an attack of abdominal pain, possibly preceded by some irregular hæmorrhage; there may or may not be a little faintness at the time. These symptoms, however, subside, though the patient is probably pregnant, and

within a few days, or possibly a week or two, the patient has a more severe attack, in which the symptoms of internal bleeding may become more marked. The physical signs met with in cases of tubal pregnancy depend on the amount of hæmorrhage and the rapidity with which the bleeding occurs. Treatment depends upon the conditions present in each individual case. In the first class—the fulminating variety, where the patient is collapsed and the pelvis and lower abdomen is full of blood—immediate operation should be advised in order to save the patient from the risk of further bleeding. It may be contended that operating on a patient collapsed from hæmorrhage is a very serious undertaking; but as a rule at the time the patient is seen the hæmorrhage has ceased, and if it has not ceased there is all the more reason for not delaying operation. The operation undertaken at this period is exceedingly simple, and takes but a short time. In the second class, where the patient is not seen till a pelvic hæmatocele has formed, the treatment, to a certain extent, depends on the time that has elapsed between the severe attack of pain and the examination of the patient. If as long as ten days, the patient having been free from pain, an expectant treatment can be safely advised. In the third class, where the patient has repeated attacks of pain, together with irregular hæmorrhage, and a unilateral swelling is found in the situation of the tube and ovary, operation is always advisable. Operative treatment is indicated in those cases where the hæmorrhage is moderate or severe and of recent origin, and also where the symptoms and physical signs indicate that the gestation sac is still contained within the tube. It is safe, however, to wait and watch the patient in cases where a hæmatocele has already formed, and where, after the initial attack of pain, the patient has been free from symptoms for a week or more. Under these circumstances there is a good chance of the blood becoming completely absorbed, and no serious risk is run by following an expectant treatment.

3. **Rigor Mortis in the Stillborn.**—Parkinson has made a study of the occurrence and significance of rigor mortis in stillborn children, and reaches the following conclusions: 1. Rigor mortis may set in under certain conditions before labor, and may pass off while the child is still in utero, and possibly may delay the birth in these cases until it has passed away. 2. Rigor mortis may set in when the child dies during labor, and may either be complete before or may go on to completeness after birth, and in those cases increases the difficulty of expulsion. 3. The child may die during labor, and be expelled before rigor mortis can set in, but rigor mortis may supervene after birth more or less completely. 4. The attitude produced by rigor mortis in stillborn children differs from that produced by cadaveric rigidity under ordinary circumstances, and by its character enables an opinion to be given that the child had no separate existence, for in every such case the limbs and body generally become drawn into the position in which it lies normally in the mother's womb. Rigor mortis is not a sign of live birth, but the character of the rigor mortis enables one to decide whether or not the child was stillborn.

7. **Migraine.**—Dobson states that the word "migraine" is the shortened form of hemicrania, and represents a definite entity, and must not be used for headaches in general. Migraine is a functional disease, characterized by paroxysmal attacks of headache, usually one sided, and which may be associated with sickness, peculiar affections of sight, and various mental symptoms. Migraine is looked upon as hereditary, but it is probably the tendency to a neurosis which is inherited. Women are supposed to suffer more than men, but the writer holds the contrary. As to the primary cause of the disease, we can only say there is a hereditary predisposition to a brain storm. When we come to the immediate or exciting causes, it is generally found that mental or bodily fatigue, worry, or eye strain are responsible. Three classes of migraine may be recognized: 1. Simple hemicrania, typical in that it is unilateral and responds to every arterial beat; it recurs every few weeks. 2. Sick headache, again periodical; unilateral headache, culminating in nausea, followed by vomiting and prostration; hereditary. 3. Blind headache. Other and more alarming symptoms which may be grafted on any case of migraine are tingling of lips or the arm, numbness of arm, drowsiness, motor aphasia, and squint (temporary paralysis of the third nerve). The headache is typical in that it responds to every heart beat, is made intolerable by stooping or coughing, and is in the great majority of cases unilateral. The character of the headache, its periodicity, and usual association with vomiting or blindness makes the diagnosis easy. The attack is one of a large group of nerve storms which are liable to sweep over the human organism—epilepsy, spasmodic asthma, tic douloureux, and others. Certain constitutions seem to accumulate stores of nervous energy, which are liberated by one of these explosive methods. Treatment consists in: 1. To lessen the tendency to the explosive action in the nervous centres. Here may be pointed out the necessity for a sufficiency of sleep, nutritious food, but not excessive in quantity, prevention of intestinal fermentation, and regular exercise. 2. To avoid the immediate exciting causes. These are gastric disturbance, constipation, and eye strain. In migraine there is no deterioration of mind.

1. **Insomnia.**—Morison holds that change in the brain cells themselves is the primary cause of sleep, and that vascular and neural changes associated with sleep are effects, not causes, of the condition. What the essential cause of these intracellular changes is, is unknown, but they undoubtedly exist. Normally, a moderate degree of exhaustion of the nerve cell from the exercise of function appears to be the essential cause of sleep. With this there may be exhaustion of other organs, and more especially of the voluntary muscular system. But, however the latter may participate in sleep production, the primary cause is the need for rest on the part of the brain cell itself. Temperament is of the greatest importance in relation to sleep and sleeplessness. The temperamental differences which influence cellular excitation, influence also disturbances of sleep due to afferent neural and to hæmic causes. Sleeplessness may therefore be classed in three groups: Cellular, neural, and hæmic. But, whatever the immediate cause of sleeplessness, the effects of it, though varying in degree, are the same in kind and the opposite of those observed in sleep. Thus, the temperature of the body is slightly raised, visceral actions are quickened, and secretion, especially the urinary secretion, is increased, not diminished. The latter phenomenon, like all the phenomena of sleeplessness, is most evident in the neurotic insomniac and is due to the higher vascular tension involved, which causes a larger excretion of urine by the kidneys, for the increased output is usually of a limpid character. 1. Cellular insomnia. The majority of cases of disturbed sleep are referable to this class. The subjective and objective causes of cerebrocellular disturbance must be distinguished. Of these the former, dealing with sensibility and emotion, are more likely to preponderate than those dealing with executive overwork. Worry kills and keeps awake more frequently than overwork. 2. Neural insomnia includes all those cases in which sleep is disturbed by afferent impulses of a more strictly physical kind. Pain and bodily discomfort originating in whatever system, be it cutaneous or pulmonary, renal or hepatic, gastric or intestinal, may rouse conscious activity and prevent its dropping into the rhythmical repose natural to it. This may be caused directly, as by pain, or indirectly, as by elevation of the blood pressure. 3. Hæmic insomnia. This is the smallest group of those into which cases of insomnia fall. Among its causes, in addition to anæmia, are elevation of the body temperature without the development of localized disease and various intoxications. The terrible insomnia of the delirious pneumonic, which frequently hastens death, belongs to this group. Drug and food agents act through the blood: also products of defective metabolism acting through the nervous system on the blood vessels and inducing a hypertonic state unfavorable to cerebrocellular repose. Vascular hypertonus of a spastic and functional type has its organic expression in the arterio-sclerotic changes of old age so often associated with defective sleep. The prognosis in cases of insomnia depends, and deal upon the reversibility of the disturbance. The rate of disturbance has on the prognosis of functional, as apart from organic, is of great value. Of the same type, some, though it is not severe, may cause the same

any way with opium and its derivatives. No agents, however, are more apt to produce the drug habit. In the absence of physical pain and visceral commotion, most of the reliable hypnotics belong to the methane group—sulphonal, trional, veronal, chloral, etc. With them may be prescribed bromides and a derivative of hyoscyamus or cannabis indica. The writer recommends the use of what he calls an "open air" pillow—a lightly padded iron frame covered by a case of smooth webbing and open at both ends, on which the head and neck rest comfortably, surrounded by air of the same temperature as that of the bedroom.

**6. Phosphaturia and Conversion of Disease.**—Harrison states that it has not infrequently been observed in the treatment of chronic urethritis and mucopurulent discharges following it, irrespectively of the internal administration of alkalies, and often imperceptibly to the patient himself, that the urine becomes altered in character and assimilated with that known as phosphaturia. And, further, that when this change is observed the cessation of the discharge or gleet, for which the patient originally came under treatment, usually soon follows, either spontaneously or by treatment appropriate to the phosphaturic state without apparent reference to the cause which preceded it. The writer suggests that the artificial production and temporary continuance of such a state of phosphaturia might be utilized in the treatment of specific gleet affections following upon gonococcal infections. To produce a urine having the prominent features of phosphaturia by the administration of alkalies—potassium bicarbonate—is not difficult nor detrimental to the patient. The effect on the urine should be sufficient to make it react to the usual tests for phosphaturia—not merely an alkaline reaction. Further, it is necessary to maintain this condition for some little time, during which all local applications should be suspended. After ten days or so, as the phosphaturic condition passes off under the influence of altered treatment and diet, it will usually be found that the original ailment has also departed.

**8. Recovery in Landry's Paralysis.**—Vining reports a case of severe acute ascending (Landry's) paralysis, which, when the diaphragm showed signs of paralysis, threatened to be speedily fatal. The diagnosis lay between diphtheritic paralysis, Landry's paralysis, and a toxic paralysis affecting the anterior cornua or nerves. There was, however, no evidence of diphtheria, or of exposure to such toxic influences as syphilis, gonorrhoea, lead, or alcohol. In this case, strychnine appeared to have a very beneficial effect.

**1. Clinical and Pathological Distinctive Diagnosis of Diseases of the Female Breast.**—Blood-good states that every palpable mass in the breast of a woman should be regarded as malignant until proof is obtained of its benignity. Previous to the age of twenty-five, lesions of the breast are, as a rule, benign. They include intracanalicular myxoma, fibroadenoma, and diffuse virginal hypertrophy. In women over twenty-five every tumor of the breast should be explored without delay. They may be malignant or doubtful. The former should be operated on by the extensive dissection devised by Halsted. In doubtful cases an exploratory incision is first made, and if malignancy is apparent the radical operation is at once performed. If it is not malignant the extent of the operation will depend upon the nature of the tumor and the condition of the surrounding breast, the procedures being excision of the tumor only, excision of the entire breast, or excision of both breasts. Clinically, doubtful tumors may be either solid or cystic, the latter being of rare occurrence. Carcinoma of the breast may be divided into adenocarcinoma, medullary, and scirrhous.

**2. Fundamental Principles in the Treatment of Functional Nervous Diseases.**—Collins affirms that the treatment of psychasthenia, like the treatment of nervous disease founded on degeneracy, consists in treating the patient and in treating the chief factor of the disorder, heredity. The neuroasthenic usually yields to treatment when the cause no longer exists and the general health is restored. The latter usually follows proper rest and exercise, massage, thermal, and mechanical agencies. The psychasthenic will usually require much more searching psychotherapy. He will need plain statement as to the nature of his ailment and the various data involved in overcoming it. He must develop selfreliance and courage. Treatment by suggestion will be of great importance, though hypnosis will usually be unnecessary and inadvisable.

Means which will improve the general health are of prime importance, also healthful reading and useful occupation. Introspection and constant questioning as to one's acts and thoughts must be overcome by paternal and pedagogical cooperation.

**3. Neurasthenia in the Young.**—Wilson narrates a number of cases in which his treatment consisted in first winning the complete confidence of the patient, then in educating the physical body to do more than it had ever done to attain perfect tone, in order that the mind and nervous system might follow the body in regaining control and balance. The patient was fed regularly, and then ample exercise was taken in the open air to consume the entire intake of food. A thorough evacuation of the bowels, artificially produced, if necessary, was always insisted upon, every morning. Exercise morning and evening to the point of physical tire, but not exhaustion, was continued, and as the muscles hardened the depression and neurasthenia diminished. Gradually selfconfidence was acquired, hopefulness in the possibility of cure became established, and after months of such treatment cure resulted. The author recognizes that the close attention and great labor which such cases require will not be possible with the majority of physicians.

**4. Nervous Manifestations of Arteriosclerosis.**—Stenzel affirms that various nervous symptoms are to be met with in this disease, some of which are consequences of the disease, while others are due to associated organic diseases. Those who suffer with arteriosclerosis are often affected at the same time with structural disease of the kidneys, heart, brain, or other organs, and it is always necessary to distinguish the symptoms caused by the associated conditions from those which are directly due to arteriosclerosis. The error must be avoided of attributing to arteriosclerosis the symptoms which result from purely accidental organic diseases when associated with it, but not essentially due to it. There is great danger of attributing all the obscure conditions of senility and even of the presenile period to arteriosclerosis. The aim of the author in this paper is consequently to point out the certain results of vascular occlusion or disease, and also the symptoms associated with arteriosclerosis, which may be attributable to that condition on account of their analogy with the symptoms of that disease, and the exclusion of other probable causes.

**9. Laryngeal Complications of Typhoid Fever.** Rieser finds nearly 300 reported cases of such complications. The following are considered causative factors: 1. Friction and irritation due to phonation and swallowing, together with constant coughing, all being produced upon a surface which is part of an organism suffering from general typhoid toxæmia. 2. A mucous membrane itself in a state of catarrhal inflammation with scollar surface pathology. 3. Thermic influences, heat or cold, in both in rapid succession, including sudden draughts. 4. Bacteria, the lymphoid tissue, or any part of the body being subject to primary invasion by the typhoid bacillus. 5. Extension of pharyngeal involvement in parotitis, with infiltration of the styloglossopharyngeal folds. 6. The closed glottis.

9. Curettage and Puerperal Sepsis. By C. E. RUTH.
10. Cases Illustrating Common Mistakes in Gynecological Diagnosis. By W. S. SMITH.

**1. The Influence of the Central Nervous System in the Causation of Uterine Hæmorrhages.**—Ehrenfest states that the endometrium was at first believed to be the cause of such bleeding. Then came the theories that the fault was in the uterine wall. Either it was a thickening of the tunica media of some of the arteries, or there is relative insufficiency of the uterine musculature with excess of fibrous tissue, or there is insufficiency of the uterine elastic tissue. None of these theories include simple functional disturbance as a cause. The author then studies the subject from the standpoint of the nervous system and draws the following conclusions: 1. Impulses from the central nervous system may alter the normal uterine function both as to menstruation and labor. 2. Vasomotor anomalies may result, such as amenorrhœa, menorrhagia, and irregular hæmorrhages, or motor disturbances such as the sudden beginning or cessation of uterine contractions. 3. The mechanism by which such nervous influence may cause amenorrhœa or metrorrhagia has not been clearly explained. With these facts in view, the effect of increase of uterine tone from whatever cause will be passive hyperemia with local increase of blood pressure and dilatation and rupture of the endometrial capillaries.

**4. Scopolamine Morphine Anæsthesia in Gynecology.**—Ries reports the results of this treatment in 185 cases, including all kinds of gynecological operations. He administers 1/50 grain scopolamine and 1/2 grain morphine in three equal hypodermatic injections, two and a half, one and a half, and one half hour before an operation. Hyoscine may be substituted for scopolamine. The patient should be kept quiet in a dark room while the injections are being given, the general preparation of the patient preceding the injections. The operations in question, in twenty-four cases, were without the assistance of other anesthetics, the patient being in a quiet sleep. Vaginal operations by this method are usually more successfully carried out than abdominal ones. Pulse and temperature undergo little change during this anesthesia but the rate of respiration is sometimes considerably reduced. Very young patients should not receive this treatment. In combination with ether anesthesia this treatment produces the best results.

**8. A Consideration of Neurasthenia in Its Relation to Pelvic Symptoms in Women.**—Weiss determined from the analysis of a series of neurasthenic patients who required gynecological examination and treatment that diagnostic error often attributes to the pelvic organs lesions which do not exist, that operations have often been recommended and performed in such cases, and that in the majority of the cases operated upon there was either no improvement or the symptoms were aggravated by the operation. He asked that these facts be borne in mind: (1) That neurasthenia may be present without any pelvic disease, (2) that neurasthenia and pelvic disease may coexist without causal relation of one upon the other, (3) that they may coexist with definite relation. The whole class of patients is very difficult to treat, and requires much patience and care in differentiating real from imaginary evils.

## ANNALS OF SURGERY.

10. The Trough Suspender Forearm Sling, By W. C. WERMUTH.
11. Partial Resection of the Upper and Lower Maxillæ for Congenital Deformity of the Face, By R. T. MORRIS.

**2. Experimental Surgery of the Lungs.**—Robinson thinks, as the result of thirty experimental operations on the lungs and pleura, that a positive pressure apparatus is better for such work than the negative pressure cabinet. Further investigations will show whether disturbances to the pulmonary and aortic systems are greater than from negative pressure methods, also the cause of pleuritic effusion and death after pneumectomy of one side. He also proposes to test different methods of thoracoplasty, including artificially produced mediastinal and diaphragmatic herniæ, to obliterate, at least partially, the unoccupied cavity. He thinks it has not been proved that interlobular abscesses and other localized inflammatory conditions of the pleural cavity may not be approached through uninvolved regions, brought to the wound, walled off, and drained as in intraabdominal operations. He then proceeds to answer the eight objections of Sauerbruch to positive pressure for intrathoracic operations, as compared with negative pressure.

**3. Should Cholecystitis and Cholelithiasis be Any Longer Considered Medical Affections, and What Are the Usual Consequences of so Treating Them?**—Nancrède thinks the importance of

certain biliary conditions and the impossibility of successfully treating them except with the knife is not sufficiently recognized. It is not necessary for a diagnosis of cholecystitis that there be jaundice, a painful tumor in the gallbladder region, chill, and fever. The author holds that cholecystitis is an infective process which precedes the formation of calculi, and implies potential dangers, with or without the formation of such bodies. The most common form of the disease is caused by germs of low virulence, but one is never sure that there may not be secondary infection, with virulent organisms, causing infectious cholangitis or suppuration or gangrene of the gallbladder. There are also possibilities of adhesions involving the stomach and intestine with permanently serious results. The absence of gallstones at an operation does not prove that none have been passed nor that others may not form.

**7. Postoperative X Ray Treatment of Malignant Disease.**—Boggs desires to emphasize the necessity of such treatment early, without waiting until recurrence has taken place. Radiation should be used in such a manner that the site of operation and the adjacent lymphatic glands will be saturated, thus producing a physiological result. It must be remembered that inadequate treatment is useless, that small doses stimulate growth of tissue, while efficient radiation retards and destroys new growths. The treatment with this agent will vary with the situation, the results for malignant disease at the surface of the body being far more satisfactory than for its interior. For cancer of the breast the following suggestions are made: 1. The breast should be removed by the radical operation and be immediately followed by x ray treatment. 2. If there is slight glandular involvement, intense x ray treatment should immediately follow an operation. 3. If the glandular involvement is extensive, intense radiation daily until axillary glands cannot be felt, then a radical operation and cautious use of the x ray.

5. Mediastinal Cancer, Occurring Ten Years after Removal of the Breast, with Secondary Nodulation Well Distributed Over the Head and Trunk, By J. SOUTTAR M'KENDRICK.
- 2. Cirrhosis of the Liver.**—Hunter had such a case in a boy, nine years of age. He remarks that as to the etiology of cirrhosis of the liver, we are still in the dark, but it seems reasonable to suppose, as a predisposing cause, an undue irritability or susceptibility of the liver tissue, which may be congenital or acquired; and, as exciting cause, a toxine of unknown composition and origin, which sometimes reaches the liver by the portal and sometimes by the general circulation. Such a cirrhosis has been produced experimentally by injecting a certain

drug into the general circulation; and it is probable that a toxine of this sort is produced over a long period and at times in greater quantity than at others, for the symptoms show, from time to time, definite exacerbations alternating with periods when the patient seems to improve. The enlargement of the spleen so often met with is probably also due to a toxæmia, which will be increased as the liver gets less efficient. Microorganisms and toxins in the blood tend to collect in the spleen, from whence they may pass again in the portal blood stream to the liver, and possibly in this way add a portal cirrhosis to what may formerly have been a biliary cirrhosis. Some explanation of this sort is required to account for the association of portal and biliary cirrhosis in the same liver.

## Proceedings of Societies.

### MEDICAL SOCIETY OF THE STATE OF NEW YORK.

*One Hundred and Second Annual Meeting. Held in Albany, January 27, 28, 29, and 30, 1908.*

The President, Dr. FREDERIC C. CURTIS, of Albany, in the Chair.

(Continued from page 281.)

**Clinical Observations on Vaccines.**—In this paper Dr. JOSHUA M. VAN COTT referred to the involved and prolonged technique with which the production of vaccines was associated, thus overcoming most of their clinical usefulness. It was this fact that had first led him to the manufacture of a vaccine composed of enough species of streptococci and staphylococci to cover all conditions. Following the use of this vaccine, he reported no untoward effects. On the contrary, the patients seemed to experience a sensation of acceleration. There was no local reaction except slight hyperæmia. All the patients vaccinated were in poor general condition and had shown no tendency to improve by any other treatment. The Bier congestive apparatus was used in three of the cases. He reported eleven cases, all of virulent infections, in which the patients were vaccinated, with only two deaths. He believed that the results obtained were sufficient to warrant a favorable report of this composite vaccine, and that we might eventually get rid of at least some of this elaborate and objectionable technique.

#### Report of Four Cases Treated by Vaccines.

In this paper Dr. ALGERNON T. BRISTOW, of Brooklyn, began by stating that the organism protected itself in two ways—by the blood serum itself and by phagocytosis. In some cases of infection the serum had no bactericidal power, and thus phagocytosis was the only antagonistic factor to infection.

Case I was that of a lady, fifty-eight years of age, who for some time, at intervals of about three weeks, had symptoms of infection and rigors. When she was first seen her temperature was 102° F. She had a swelling on the side of the neck, moderately painful upon pressure. The blood count showed 14,000 white blood cells. A few days later the pain was less, the swelling was more diffuse, and there

was a white count of 10,000. An operation was done, which consisted of a long incision, parallel to the sternocleidomastoid muscle. The abscess was opened and pus evacuated and the abscess drained. Five days after the operation a culture from the wound showed a mixed infection with streptococci. She was vaccinated with 5,000,000 streptococci, obtained, not from her own organism, but from a stock vaccine. Following this her temperature rose, she had a convulsion, and she required active stimulation. A second dose of 10,000,000 was then given a few days later, and from this time the patient steadily improved.

Case II was that of a girl, aged twenty-one, brought to the hospital with a history of rheumatism. Her general condition was bad, and streptococci were found in the blood. She had headache, some retraction, and pain in the joints. She was given antistreptococcus serum for several doses, but without any beneficial effect. She subsequently received three doses of vaccine of 5, 10, then 5 million streptococci. Following the last dose there was an uninterrupted recovery.

Case III was that of a nurse suffering from furunculosis. Culture showed staphylococci. A vaccination was made from her own organism. Following its administration she remained free for some months, then a second furuncle developed. She was revaccinated, and it rapidly cleared up.

Case IV was that of a boy, eighteen years of age, suffering from gonorrhœal arthritis. He had a high temperature, and the joint was swollen and painful. Seventy-five million gonococci were given and repeated in four days. In a week the boy was up on crutches, and a rapid improvement followed.

Dr. Bristow regarded these results as sufficiently striking to warrant a thorough investigation of vaccine therapy upon the part of those who were not familiar with it.

**A Description of the Methods of Sir A. E. Wright.**—Dr. WILLIAM H. WOGLOM mentioned the three elements necessary for the test, viz., the serum, the washed leucocytes, and the organism. He described the method of obtaining the washed leucocytes by dropping the blood into a one and a half sodium citrate solution, centrifuging, pipetting off the supernatant fluid, rewashing, and recentrifuging with a sodium chloride solution, causing the separation of the leucocytes, which were designated "washed leucocytes." The collection of the serum was then explained; the use of the glass capsules, the sealing in the flame, etc., also how the clot formed and how the capsule could be broken when the serum was to be tested.

To make the "bacterial emulsion," a twenty-four hour culture was advised. Some of this was taken on a flat loop and mixed with normal saline solution. The thickness of the emulsion could best be determined by experience.

Mark off some amount on the pipette and call it volume. Take one volume of washed leucocytes and then one volume of the bacterial emulsion, allowing a bubble of air to interpose between them, then one volume of the patient's serum with a bubble of air between them. Then blow out upon a slide and mix. The mixed solutions are then drawn up in a pipette and left for ten or fifteen

minutes to incubate. Then go through the same process, using normal serum, which might be obtained from a "pool" of many normal bloods. The object of this was a control. Blow off a drop from the pipette upon a glass slide, and smear with a smearer whose edge was slightly concave. Then count at least one hundred leucocytes, both those which had "phagocytized" and those which had not. The average number of bacteria found in the leucocytes actuated by the patient's serum was then divided by the average number of bacteria found in the leucocytes actuated by the serum from the pool. The result obtained would be the patient's index.

**The Value of the Opsonic Index in Controlling the Use of Vaccines.**—In this paper Dr. WILLIAM H. PARK declared that to Dr. Wright belonged the credit of causing and stimulating the profession to use vaccines, and that it would take years to learn the limits of the opsonic work. He referred to the fallacies of the technique and the results, not only in the hands of American workers, but as done by the assistant of Dr. Wright himself. So he advised that but little dependence be placed upon only determination. The difficulties of the work were said to lie in three main causes: 1. The personal equation in counting. 2. The irregularity with which the leucocytes would take up bacilli. 3. The difficulty of technique; one could not always take the same number of blood cells and of bacilli.

Besides this, he continued that the proper culture must be obtained, viz., from the individual affected; that each day the pool of normal blood must be renewed (and this would vary), and that the irregularity of the disease lent its weight in making the determination more difficult. He declared that the opsonic power was not the only protective element in the blood, but one of many.

He reported a series of examinations by ten different laboratories, all of the same specimens of blood. The results of the laboratories, while very interesting, showed marked variation, and the results only emphasized the fact that little dependence could be placed upon one determination. He recalled his visit to England and to the hospital in which Dr. Wright carried on his investigations. He said that the patients, while not doing as well as Dr. Wright in his enthusiasm would lead one to suppose, were on the whole benefited by this method of treatment. He stated that Dr. Wright himself thought the index to be of little clinical importance. He concluded by affirming that the results obtained in England were no more accurate than those of American workers.

Dr. Rochester asked if a low index to any organism would warrant a diagnosis of an infection by that particular organism, and whether, before using a vaccine, the cultural method was used, or simply the vaccine from the germ found in a given case, or if the vaccine was made from a stock culture.

Dr. BOSWELL, of Rochester, wished to know if all the phagocytes were counted, or if the method of Sim was employed.

Dr. PARK said that Dr. Wright himself used the index but little for diagnostic purposes. But he asserted, if a marked variation of the index to any particular organism occurred it usually pointed to an invasion by that organism. In reply to Dr. Boswell,

he answered that as a rule he counted all the phagocytes, though he did sometimes use Sim's method.

**The Importance of Examination of Those Who Have Been Exposed to Tuberculosis.**—Dr. JOHN H. PRYOR, of Buffalo, read this paper. He quoted the annual death rate from tuberculosis in New York State as being about 14,000, which constituted one tenth or one eleventh of the total number of deaths in one year. He declared tuberculosis to be endemic in its nature and the influence of preventive measures to be open to discussion. Outside of New York, he considered the matter of prevention a delusion and a snare, and the whole system a matter of diplomacy between the physicians and the various health departments. He declared that the solution of this problem called for rigid laws and an adequate knowledge on the part of health officers before their appointment. He referred to the utmost importance of an early diagnosis, and said that the profession must learn to find the victims early, and that no case of tuberculosis should be allowed to reach the stage when the patient could give the disease to another before preventive measures were instituted.

He believed that thorough and repeated examinations of those who had at any time been exposed to the disease should be carried out, and that the disinfection of apartments after death should be complete, and not done in the slipshod manner in which it was often carried or not carried out.

He asserted that the physical signs did not always give an index of the extent of the disease, and that if earlier hemorrhages were common, the diagnosis would be easier. In his opinion exposed persons should be instructed as to the early symptoms of the disease and kept under constant observation. Underfed persons were especially susceptible, so tuberculosis was largely a disease of the poor, and he lamented the fact that the practitioner often overlooked the disease in its early and most favorable stages.

He cited an outbreak in an institution as a striking example of common and fatal indifference. In this instance a nurse was found to have tuberculosis. The entire force of nurses with whom she was associated was examined, and out of thirteen nine were found to be suffering from the disease; also a boy who was employed there proved to be infected. This only showed the indifference with which most people regarded this great scourge.

Dr. GOODALL agreed with Dr. Pryor as to the importance of early diagnoses, and stated that when tubercle bacilli could be found in the sputum ulceration had already taken place, and that if the case could be recognized before ulceration had occurred, the prognosis would be infinitely better. He believed also in hunting out the cases.

To emphasize the importance of exposure, he cited a series of pleurisy cases. Of those who subsequently had tuberculosis, sixty-five per cent. had been exposed, and of those who did not have the disease later only twenty-five per cent. had been exposed.

He believed that the mortality record of tuberculosis had increased in the last few years, possibly because of keener diagnoses, and not because of any greater frequency of the disease.

Dr. ROCHESTER congratulated Dr. Pryor upon the general excellence of his paper. He stated that he examined the nurses and boy in the institution re-

ferred to by Dr. Pryor, and that he recommended that the boy be sent to the Erie County Hospital and the nurses to Ray Brook, but that not one recommendation had been carried out by the trustees of the institution, and that the boy was retained in its employ till Monday, January 10th. He regretted exceedingly that it was so difficult to get the people to carry out the physician's suggestions, or even orders.

Dr. PRYOR in reply to Dr. Goodall stated that the death record was still probably too low as compared with the actual situation; many cases of tuberculosis were entered upon the death certificate as pneumonia or heart disease for insurance purposes.

**The Treatment and Prognosis of Suppurative Cystitis.**—In this paper Dr. V. C. PEDERSEN said that there was but little new in the treatment or prognosis of suppurative cystitis. Inasmuch as the bladder was never at rest it was a difficult organ to treat, and the treatment would depend upon the character of the inflammation and the degree of the effect. If the functional powers were totally impaired, the organ would never return to its normal condition. He declared that in the treatment the first step should be the removal of the cause whenever it was practicable, such as the dilatation of strictures, the removal of vesical calculi, or treatment of the prostate. Tuberculosis and cancer being hard etiological factors to remove, the prognosis was correspondingly worse.

As to constitutional treatment, he advocated good hygiene, plenty of sleep, and regulation of the bowels, especially in old people. A change of climate and avoidance of excesses in food, alcohol, or physical exercise, vesical fatigue, or irritation from highly seasoned foods, were also advised.

In cases where the urine was alkaline he recommended urotropin given in large doses up to toleration, as much as a drachm in twenty-four hours. He believed the balsams to be beneficial, but they were not to be given if the stomach showed any tendency to rebel. Irritants, such as cantharides and oil of turpentine, were to be avoided, but he did advise irrigation, inasmuch as it stimulated, cleansed, and soothed the mucosa of the bladder, and was a mechanical aid in removing mucus, etc. In this procedure he preferred the soft rubber catheter and a normal solution of salt or of sodium bicarbonate injected till the return fluid was clear even in a test glass. The posture of the patient did not make much difference. The fluid used should be about the bodily temperature, but the heat might be increased to 110° or 115° F. From two to four ounces should be used at a sitting, though in old cases with a dilated bladder from eight to sixteen ounces might be employed. The success of this operation depended upon the degree of comfort afforded and the lack of tenesmus.

In chronic cystitis the mucous membrane should be stimulated, but not irritated. If any antiseptic was used in the irrigation some of it might be left in the bladder. The treatment should be repeated when the symptoms returned, but some bladders required irrigation daily, while others might be quiescent for five or six days. When tenesmus occurred, he believed it to be due to too irritating solutions, undue trauma, or emptying the bladder too rapidly. In

some instances he advised the maintenance of the knee chest posture during treatment, especially if there were accumulations in the bladder wall. The indwelling catheter was more applicable to women. Unless the organ was badly damaged, the prognosis was usually favorable. Many bladders, however, might recover up to a certain degree, but never entirely.

**The Sequence of Pathological Changes in Appendicular Peritonitis.**—Dr. E. MCD. STANTON presented a study of 1,019 cases. He admitted the sequence of the pathology to be complex, varying from day to day, and running a definite course either toward resolution or toward abscess. In general it was seen that when peristalsis was arrested, only a local peritonitis occurred, but, on the other hand, if cathartics and food had been given, the infection was disseminated by the movements of the intestines.

Following inflammation the exudate might be of two varieties, fibrinous, or dry, and serous or sero-purulent. The dry variety formed adhesions to the omentum, the liver, the end of the cæcum, the parietal peritonæum, and some coils of the intestine, and these bands of fibrin were later replaced by granulation tissue which walled off the pus cavity. Though these granulations were soft and weak at first, they were usually sufficient to confine the abscess, provided peristaltic movement was effectively arrested.

In the second variety, with the fluid exudate, it was shown that there was little or no evidence of localization, especially in the early stages. In cases of this type operated in upon the first day there was intense congestion of the peritonæum, but otherwise no change. In second day operations the exudate was found to be more diffuse, with some few feeble adhesions and slight dullness of the peritoneal surface. Upon the third day there was apt to be a purulent exudate, with more adhesions of fibrin, but the lesion was so extensive that no sharply defined abscess cavity could be made out. By the fourth or fifth day organization was well established and definite abscess cavities were then discernible. Upon the fifth or sixth day there would be definite evidence of abscess formation. Then, it was observed, there would be a progressive diminution in the extent of the area involved, with resolution of the peritonæum outside of the abscess cavity; and on the tenth or eleventh day there would be left but slight, if any, evidence of inflammation in the general peritoneal cavity. Thus three stages of the disease were said to exist: 1. When there was no marked alteration of the peritonæum, requiring only temporary drainage. 2. During peritoneal irritation, when an operation was not advisable. 3. When the peritoneal abscess had formed and drainage constituted the operation.

The object of his paper was to establish the fact that the distribution of an intraperitoneal infection was purely mechanical, due to the movements of the intestines.

Dr. OCHSNER said that he had looked forward to the exposition of the living pathology of this condition and especially in a large series of cases. He believed the paper so complete and that it must henceforth stand as a basis of our knowledge of the

pathology of acute appendicitis. Eight years ago he had brought out the proposition, then heretical, that the distribution of infection and the consequent mortality depended not so much upon the primary disease as upon its dissemination throughout the peritoneal cavity by the peristaltic action of the intestines, and eight years before that he had believed it possible to limit the infection, provided peristaltic action could be arrested. This was best accomplished by withholding food and by gastric lavage, possibly adding rectal feeding more for the benefit of the friends than of the patient. He believed that quiescent symptoms were often lighted up and infection spread by an abdominal examination or the administration of food or cathartics. The paper showed to his satisfaction that if advantage was taken of the anatomical relations the abscess would be walled off and the outcome of most cases favorable. He believed that the superiority of this treatment had been conclusively demonstrated.

Dr. W. G. MACDONALD discussed the paper adversely, and expressed the opinion that no artificial chronological division of pathology or symptoms could be made in any surgical or medical disease.

Dr. MONRO, of Boston, commended Dr. Stanton for the high order of his communication, and agreed with him that the pathology could be identified day by day.

Dr. SKINNER stated that the facts set forth in the paper coincided with his own observation in cases where there was no operation. He disagreed with Dr. Macdonald and referred to the chronological cycle of various functions, such as the pulse, respiration, menses, etc., and also to the fact that in cases of peritonitis treated by this method the bowels usually moved on or about the tenth day.

Dr. LAKE expressed his extreme pleasure in listening to the paper, because it recalled the early teachings of Alonzo Clark, and he said that it seemed good to him to hear a surgeon say, "Don't operate; wait."

Dr. BUTLER cited his own case as a child, when he suffered from peritonitis. He stated that he was kept under opiates for about six weeks. The unusual feature of the case was that he had a localized abscess, which ruptured into the bladder, and the pus escaped with the urine.

Dr. A. VANDER VEER asked as to whether or not the disease was progressive as to the number of attacks, and he wished to know the history of the second and third attacks. He believed that in a gangrenous and perforative appendicitis the best chance was given to the patient by an immediate operation.

Dr. STRANAHAN cited a series of one hundred cases treated by Ochsner's method with no deaths, and he stated that this series included all kinds of cases.

Dr. OCHSNER, in reply to Dr. Vander Veer, declared that every patient seen during the first thirty-six hours should be operated upon, because the condition of the peritonæum was still such that it would be restored to the normal condition by only temporary drainage. But on the second, third, or fourth day an operation was decidedly contraindicated. The procedure he recommended in those cases was to wash out the stomach, apply an abdom-

inal bandage, and use rectal feeding, giving along with the enema 10 to 30 drops of the deodorized tincture of opium. Slow, continuous rectal irrigation might be employed if the patient was thirsty, and if nausea or vomiting occurred he would wash out the stomach.

Dr. STANTON, in reply to Dr. Macdonald, stated that until he undertook the study of this subject he too had not believed in any chronological order of pathology, but he declared that even in the saline treatment a certain attempt at a chronological order could be made out, and that the death rate was not one seventh of what it was in cases of operation on the third, fourth, or fifth day. In reply to Dr. Vander Veer, he stated that recurrent attacks were more severe and more apt to perforate.

**Diffuse Peritonitis in Women.**—Dr. ELLICE McDONALD said in this paper that he believed the prognosis to depend upon the cause, and it might be puerperal infection, perforation of a gastric or intestinal ulcer or the gallbladder, or infections from the bowel. Peritonitis from appendicitis in women was much less common than in men, but women seemed especially predisposed during the puerperium. The difficulty of diagnosis when it was associated with puerperal infections of the uterus was pointed out. In the treatment he considered raising the general resistance by vaccines and the leucocytosis by nucleinate of sodium to be of great importance.

Dr. JAMES N. VANDER VEER exhibited a case of carbuncle on the back of the neck, and showed the Bier congestive apparatus and its application.

**Hereditary Syphilis.**—In this paper Dr. G. W. WENDE stated that the symptoms might appear at birth, about the third week, at the third month, or even later. The lesions present were more active than those of acquired syphilis, and they might attack any organ. There was often no room for hesitation, but then snuffles were pointed out to be only a matter of degree, and might be due to coryza, or the skin lesion might be closely counterfeited by eczema.

The epidermis was often macerated, and bullæ might be found on the hands and feet. This last condition indicated a serious type of disease, and the child usually died. Then, again, children might be born apparently normal and remain so for a few months, and then show lesions about the lips or a pustular eruption somewhat resembling that of the acquired form of the disease.

The tubercular syphilide was not so commonly observed in the hereditary as in the acquired form, but it did sometimes occur on the scalp or even on the rest of the body. He believed syphilis to be responsible for delayed dentition; this dental involvement might include all the teeth or only the incisors. Hutchinson's test teeth were the two upper permanent incisors, and their outer edges, if continued down, would meet at a point. This deformity was said to be due to a stomatitis which had existed in the first week of life, and if the infant escaped this stomatitis the teeth would be normal. Teeth when first cut might not show any notch, but they were usually friable and the enamel was scaly. If notches existed they usually disappeared about the twentieth year.

He defined syphilitic pseudoparalysis as an inabil-

ity to control muscular movements due to separation of an epiphysis. It was said to be not a true paralysis, but an atrophy of disuse. The speaker declared it to be due to a gummatous osteomyelitis in early childhood. Joint lesions resulting from hereditary syphilis were practically the same as those resulting from the acquired form. The bones might be large, globular, and of bony hardness, or might be atrophic and associated with ankylosis. In hereditary syphilis the bones were said to be more often affected than in the acquired type, because the bones of young children were more susceptible to pathological processes.

**The Clinical and Historical Features of Acquired Syphilis.**—Dr. J. A. FORDYCE, in this paper, pronounced extragenital initial lesions of acquired syphilis to be relatively common, but often mistaken for malignant disease, especially when occurring on the lip, where they were infiltrated and irregular and resembled a beginning epithelioma. As a rule, the initial lesions were said to be single, but they might rarely be multiple, especially about the nipples of a wet nurse who had suckled a syphilitic child.

The secondary lesions included a papular and sometimes a pustular eruption, which could easily be mistaken for smallpox or vice versa. Pigmentation might persist in the site of these lesions, especially in nephritics. On the other hand, the eruption might be scaly and resemble psoriasis.

The circinate form of eruption was referred to as existing principally in the negro race, and attention was called to the similarity between the eruption caused by potassium bromide in susceptible individuals and some manifestations of syphilis.

The rarity of gummata of the palm was pointed out, though they were sometimes present, but they were apt to develop along the inner side of the leg.

The spreading of a seriginous syphilide was explained by the spreading thrombosis of minute vessels. The giant cells met with in syphilis were believed to be of vascular origin, because in this disease the muscular layer of the bloodvessels was markedly thickened.

**The Technique of an Efficient Operative Procedure in Malignant Disease of the Skin.**—Dr. SAMUEL SHERWELL, of Brooklyn, read this paper. He said that he did not claim novelty as to method or absolute perfection as to result for the procedure to be described, but he had used it for thirty-five years with good results and relatively few recurrences. He recommended simply curettage, but thorough, deep, and efficient, followed by the immediate and thorough application of an escharotic, preferably a sixty per cent. solution of acid nitrate of mercury. The caustic agent must be neutralized by some alkaline medium; he preferred common sodium bicarbonate in powdered form. This formed a scab, which was allowed to remain till it fell or was pushed off by the process of repair beneath. He said the scar was relatively insignificant. The knife was perhaps preferable in pendant and loose portions of the body, such as the penis, the lips, and the ears, but in many of these cases even he preferred the method here described. He objected to the x-ray and radium because of time, expense, and uncertainty of result.

He advised great caution in diagnosis, the slow

growths being often tertiary syphilitic manifestations. Ulceration of the nasal septum where it joined the lip, or any tumor involving the nasal cartilages, was more characteristic of syphilis than of epithelioma. But sarcoma was appropriately treated by this method.

He seldom found it necessary to use general anesthesia. The curette used should have a clean wire edge. He preferred nitrous oxide gas where general anesthesia was necessary. Before giving a general anesthetic he introduced two or three drops of a two per cent. solution of cocaine about the edges of the affected part and at the same time, with the same needle, gave a hypodermic of about 1/4 to 1/3 of a grain of morphine, with or without atropine, in a distant part of the body. The larger curette was used with force in, around, and about all parts of the affected area, so as to remove all morbid tissue. Smaller curettes could then be used in sinuses and anfractuositities with energy; there was no need to fear hurting sound tissue. He used a Paquelin cautery, a solution of adrenalin, and a ten per cent. cocaine solution to check persistent bleeding, followed by acid nitrate of mercury in full sixty per cent. strength, mopped on with cotton wool mops of the bulk of a pea. This was the painful part of the procedure, but the pain was controlled by the anesthesia. The amount of touching with acid nitrate could be learned only by experience; he frequently allowed it to remain for from ten to twenty minutes before neutralization. The last step was the introduction of bicarbonate of sodium into the excavated surface, pressed firmly down to make an adherent scab. This turned yellow and later black, and usually came off in a fortnight or three weeks. It should be kept dry. He did not use bandages. Inflammation followed at the site after a day or two, but no dressing, and particularly no wet dressing, must be used. It would soon go down.

He considered the chances of recurrence far less than those that followed the use of the knife, for the following reason: The less viable cells of which malignant growths were composed must perish under conditions which would little if at all affect the normal; the inflammation itself and the absorption of the potent alterative escharotic element by the lymphatics caused the breaking down and destruction of those cells into innocent waste products to be cast off by the economy. This was the only way he could account for the nonliability to recurrence. He always put his patients on a course of arsenic for a long time after these operations, intermittently for months, even years. He was no admirer of arsenical preparations in ordinary skin disease, but did believe in their inhibitive virtues in sarcoma, and possibly in epithelioma and carcinoma, and referred to the beneficial action of arsenic on the economy in the destruction or prevention of malignant cell life.

He said he had used this procedure for many years with success, having performed over forty operations during the past year. Relapses had occurred in less than ten per cent. of the cases, and he did not hesitate to urge his colleagues to adopt this measure in appropriate cases.

**A Study of Four Hundred Cases of Epithelioma.**—In this paper Dr. L. D. BENCHAM referred to the many statements regarding the cause of

epithelioma, and said that none was universally adopted. He spoke of the striking resemblance that these lesions had to syphilitic ulcers, and said that because of this similarity many were improperly diagnosed and erroneously treated. He believed the prognosis to be directly dependent upon the wisdom with which the lesion was treated from the time of its inception.

He did not consider heredity to be an important factor, and declared that epitheliomata might disappear spontaneously or under proper local applications. He found them to be more frequent in males, and especially between the ages of thirty-five and fifty-five.

He made a pathological classification of epitheliomata, as those originating from the basement layer of the skin and those developing from the prickle cells. In those developing from the basement layer of the skin the progress was seen to be slower, and they might show evidences of spontaneous healing. They did not give rise to metastases, and were amenable to treatment, notably with the x ray. They occurred most often on the face.

The second form of epithelioma, growing from the more superficial layers, showed mitotic figures and epithelial pearls microscopically. This variety did give rise to metastases, was more rapid in its growth, and was apt to occur at a mucocutaneous junction. Bland ointments had apparently cured lesions similar to the epitheliomata of the second variety. He cautioned the general practitioner against the indiscriminate use of silver nitrate. He referred to the constant changing of treatment in the past thirty-five years, but said that the results depended upon the stage of the disease and the completeness of its removal. He still thought that the knife offered the best and surest method of removal. Patients treated with arsenic paste often recovered, but the process was slow and painful, and this form of treatment had largely been superseded by the x ray. Curetting, combined with other methods, such as cauterization, was recommended, but it had to be thoroughly done. The escharotic which the speaker preferred in connection with the curette was pyrogallie acid. He believed that the x ray presented the greatest advantage in the treatment of certain cases of epithelioma. But, as this agent had been used in this connection only for the past five years, too much confidence must not be placed in it yet.

(To be continued.)

### Book Notices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

**Poisons: Their Effects and Detection.** By ALEXANDER WYNTER BLYTH, M. R. C. S., F. I. C., F. C. S., etc., Barrister at Law, Public Analyst for the County of Devon, etc., and MEREDITH WYNTER BLYTH, B. A., B. Sc., F. I. C., F. C. S., etc., Public Analyst for the Borough of Brighton and for the Borough of Eastbourne. Fourth Edition, Thoroughly Revised, Enlarged, and Rewritten. With Tables and Illustrations. London: Charles Griffin & Co., Ltd., 1906. (Through D. Van Nostrand Company, New York.) Pp. xxxii-772. (Price, \$7.50.)

In this new edition of the standard work in the

English language on toxicology the author has by expansion in some directions and condensation in others provided much additional information without increasing the bulk of the volume over that of the preceding edition. The book has been brought well up to date by descriptions of several of the medicinal substances introduced within the past decade or so, which have been found to cause poisonous effects through prolonged use or excessive doses. Thus, the poisonous effects of and the antidotes for the sulphones—sulphonal, trional, and tetralol—receive mention in paragraphs under the heading Minor Anæsthetics and Narcotics. Adrenalin, called epinephrin by the author, has a subchapter to itself under Mammalian Poisons, and it is further distinguished by being described as the most powerful of all modern poisons. There is no work on toxicology more accurate and comprehensive in its treatment of the subject than Blyth's book, and to such as make its acquaintance for the first time the introductory chapters on The Old Poison Lore and the Growth and Development of the Modern Methods of Chemically Detecting Poisons form very interesting reading, the romance of the poisons and poisoners of history being finely brought out. The fact that the book has reached a fourth edition is evidence in itself of the value which has been placed upon it by succeeding generations of teachers and students. We are glad to reiterate our previously expressed good opinion of the work and commend it as a volume of indispensable value to both students and practitioners of medicine.

**Blood Examination and its Value in Tropical Disease.** By CLAUDE F. FOTHERGILL, B. A., M. B., M. R. C. S., L. R. C. P., etc. With a Preface by Major RONALD ROSS, F. R. S., C. B., Professor of Tropical Medicine, University of Liverpool, etc. London: Henry Kimpton, 1907. Pp. 34. (Price, 60 cents.)

Dr. Fothergill's essay is intended to show the value of blood examinations in the diagnosis of tropical diseases. There are very few tropical diseases in which a blood examination is not the most important examination to be made. It is always necessary to exclude malaria and its influence in all kinds of disorders of tropical and subtropical diseases. We can as well imagine a physician determining that a patient has fever without using a clinical thermometer as we can imagine a physician forming his opinion on a disease of the tropics without studying the blood. We dare say that there are physicians who would undertake to do both. For such the essay of Dr. Fothergill is especially suitable.

**Reflections on Plague and the Methods of Checking it.** (With Letters to the Press.) By PESTONJEE M. KANGA, B. A., LL. B., Solicitor, High Court, Bombay. Bombay: Bombay Education Society's Press, 1907. Pp. 74.

It is a difficult matter for an American to appreciate the obstacles in the way of hygienic advancement in a country like India. It would seem that now that the relation between the rat and the flea and the spread of plague was proved, it would be a simple matter to rid a community of rats and fleas and plague. The essay of Mr. Kanga and his letters to the press of Bombay show that this is not so. Mr. Kanga's ideas are sound, and if the government and people of India could come to some workable understanding in the matter of housecleaning it

**Public Health and Marine Hospital Service:**

*Official list of changes of stations and duties of commissioned and noncommissioned officers of the United States Public Health and Marine Hospital Service for the week ending February 22, 1908:*

BAHRENBURG, L. P. H., Passed Assistant Surgeon. Granted leave of absence for twenty-one days from February 23, 1908.

FRIEDMAN, H. M., Acting Assistant Surgeon. Granted leave of absence for one day on account of sickness, February 10, 1908.

KEATLEY, H. W., Acting Assistant Surgeon. Granted leave of absence for eight days from February 18, 1908.

McCoy, G. W., Passed Assistant Surgeon. Granted leave of absence for one month and twenty-one days from November 28, 1907, on account of sickness.

MILLER, CHARLES, Pharmacist. Temporarily relieved from duty at the Marine Hospital at San Francisco, Cal., and directed to report to Passed Assistant Surgeon Rupert Blue for special temporary duty.

PARKER, T. F., Acting Assistant Surgeon. Granted leave of absence for two days from March 4, 1908.

STANTON, J. G., Acting Assistant Surgeon. Granted leave of absence for twenty-one days from February 14, 1908.

TAPPAN, J. W., Acting Assistant Surgeon. Directed to proceed to Douglas, Arizona, for special temporary duty; upon completion of which to rejoin his station at El Paso, Texas.

THOMAS, A. M., Pharmacist. Temporarily relieved at the Angel Island Quarantine Station, Cal., and directed to report to the medical officer in command of the Marine Hospital station at San Francisco, Cal., for temporary duty.

*Board Convened.*

A board of medical officers was convened to meet at San Francisco, Cal., February 21, 1908, for the purpose of making a physical examination of an officer of the Revenue Cutter Service. Detail for the board: Surgeon H. W. Austin, chairman, and Passed Assistant Surgeon C. H. Gardner, recorder.

**Army Intelligence:**

*Official list of changes in the stations and duties of officers serving in the medical department of the United States Army for the week ending February 22, 1908:*

CRAIG, C. F., Captain and Assistant Surgeon. Advanced to the rank of captain, to date from February 18, 1908.

DALE, F. A., Captain and Assistant Surgeon. Ordered to Fort Lincoln, N. D., for duty.

FLAGG, C. E. B., Captain and Assistant Surgeon. Resignation as an officer of the Army has been accepted by the President, to take effect April 15, 1908.

GRAY, W. W., Lieutenant Colonel and Deputy Surgeon General. Granted leave of absence for one month.

HANNER, J. W., Captain and Assistant Surgeon. Granted leave of absence for two months and seven days, from February 19, 1908.

MCANDREW, P. H., First Lieutenant and Assistant Surgeon. Ordered to Fort Slocum, New York, for duty.

PEED, G. P., Captain and Assistant Surgeon. Will proceed on or before the expiration of his present leave of absence to Fort Ontario, New York, for duty.

SILER, J. F., First Lieutenant and Assistant Surgeon. Will proceed on or before expiration of present leave of absence to Fort Des Moines, Iowa, for duty.

**Navy Intelligence:**

*Official list of changes in the medical corps of the United States Navy for the week ending February 22, 1908:*

BAKER, M. W., Passed Assistant Surgeon. Unexpired portion of sick leave revoked; ordered to the Naval Hospital, New York, N. Y.

BELKNAP, J. L., Assistant Surgeon. Detached from the *Wabash* and ordered to the naval training station, Newport, R. I.

HEINER, R. G., Passed Assistant Surgeon. Detached from the *Wasp* when placed out of commission and ordered to the *Pennsylvania*.

KENNEDY, J. T., Surgeon. Detached from duty with naval recruiting party No. 3 February 29th, and ordered to the naval recruiting station, Dallas, Texas, March 2d.

RICHARDS, T. W., Surgeon. Ordered to the *Colorado* February 22d, when discharged from treatment at the Naval Medical Hospital, Washington, D. C.

SCHALLER, W. F., Assistant Surgeon. Detached from the *Pennsylvania* and ordered to the *Relief*.

TAYLOR, E. C., Passed Assistant Surgeon. Detached from the Naval Hospital, New Fort Lyon, Colorado, and resignation accepted.

WILSON, G. B., Surgeon. Detached from the *Colorado* and ordered to the *Wabash*.

**Births, Marriages, and Deaths.***Married.*

BARTON—TOWNSEND.—In Richmond, Virginia, on Tuesday, February 18th, Dr. Posey L. Barton and Miss Bessie Townsend.

BERAUX—MAUMUS.—In New Orleans, Louisiana, on Wednesday, February 12th, Dr. L. A. Beraux and Miss Anita M. Maumus.

JUSTICE—WOODRUFF.—In Philadelphia, on Wednesday, February 5th, Dr. Crawford Tait Justice and Miss Elsa Marguerite Woodruff.

LUPTON—WOODS.—In Charlottesville, Virginia, on Wednesday, February 12th, Dr. Frank Allemond Lupton, of Birmingham, Alabama, and Miss Mary Watts Woods.

McCANN—BELLERBAUX.—In Louisville, Kentucky, on Friday, February 14th, Dr. Frank E. McCann and Miss Catherine Crystal Bellebaum.

MAGEE—DONNELLY.—In Trenton, New Jersey, on Wednesday, February 13th, Dr. David M. P. Magee, of Philadelphia, and Miss Suzanne C. Donnelly.

*Died.*

ARMISTEAD.—In San Francisco, California, on Thursday, February 6th, Dr. Cecil Armistead, aged thirty-seven years.

BROWN.—In Providence, Rhode Island, on Saturday, February 15th, Dr. Lucy A. H. Brown, aged sixty-six years.

CROOK.—In Glenwood Springs, Colorado, on Friday, February 14th, Dr. J. J. Crook, aged eighty-one years.

GRAHAM.—In Denver, Colorado, on Friday, February 14th, Dr. John W. Graham, aged sixty-four years.

HEUCHLING.—In Evanston, Illinois, on Monday, February 10th, Dr. Theodore W. Heuchling, aged sixty-nine years.

HODGSON.—In Roanoke, Virginia, on Saturday, February 15th, Dr. Wilmer Hodgson, aged sixty years.

KLOCK.—In Mahanoy City, Pennsylvania, on Saturday, February 1st, Dr. H. A. Klock, aged sixty-four years.

LE CRONE.—In Columbus, Ohio, on Wednesday, February 12th, Dr. Thomas W. Le Crone.

LEWIS.—In Tip Top, Harden County, Kentucky, on Thursday, February 13th, Dr. J. C. Lewis, aged sixty-three years.

PEASLEE.—In Schodack Landing, New York, on Saturday, February 8th, Dr. John Peaslee, aged fifty-eight years.

PEIFFER.—In Louisville, Kentucky, on Monday, February 17th, Dr. Robert M. Pfeiffer, aged fifty-one years.

RENICK.—In Butler, Missouri, on Friday, February 14th, Dr. O. F. Renick, aged eighty-three years.

STARR.—In Washington, D. C., on Saturday, February 15th, Dr. William M. Starr, aged one hundred and one years.

WOOD.—In West Chester, Pennsylvania, on Wednesday, February 12th, Dr. Henry C. Wood.

#### PSYCHIATRIC EXPERT EVIDENCE IN CRIMINAL PROCEEDINGS—ITS IMPERFECTION AND REMEDY.\*

By GEORGE W. JACOBY, M. D.,  
New York.

Every important criminal trial in which the question of the insanity of the accused forms part of the defense is followed by a discussion about medical experts and medical evidence in which both professions, that of law and that of medicine, take part.

The lawyer looks upon medical evidence as an unsatisfactory kind of testimony and attributes this to the inexactness of medical science, or to reasons still less flattering; the physician, on the other hand, sees the causes in the defects of the law or in the manner of its application, and reflects in general against the practice of our courts.

Certain it is that judges and juries do not receive this testimony with the respect and confidence which is accorded to it in other countries, and it devolves upon us, as alienists and neurologists, as the ones who are consulted in the class of cases referred to, to investigate whether the fault lies entirely in ourselves or only partly so, and to consider whether a situation which has become intolerable to all of us cannot be altered.

It has become proverbial that every nation possesses the government which it deserves, and it may be said, with even more justice, that an independent people such as we are possesses the government which it desires. This is true not only of the government in general, but it also applies to each single link in the commonwealth, to every dispositive of our legal activity, to each single law, whether the latter be fundamental in character and of all pervading import, or insignificant in its activity and immaterial in its consequences.

If we have the laws which we desire, we must also desire the necessary sequences of the laws which we have, inasmuch as the laws exist for the purpose of regulation of our outward life. On the other hand, are we discontented with the results produced by the application of our laws, then it follows that our laws and our will are no longer in unison.

It is often not easy to take the decision to alter laws under which we have grown up. Our concepts of what is right and what is good develop with time and with progress in conditions of existence, becoming modified according to the altering conditions

of society and culture, whereas the laws themselves correspondingly change but little or not at all.

Then it may occur that gradually and imperceptibly there develops, between the concept of the law and the law itself, a disparity which at a given moment, at some special happening, becomes manifest as a gross discord, and then a law which heretofore has filled its mission in an approximatively thorough manner, but has not kept pace with the progress of the times, nor with us, may appear as a very questionable fabric.

On the other hand, all of the unsatisfactory manifestations which evidence themselves under the workings of a law are not always due exclusively to inadequacies of this law.

Frequently the cause for disaffection is to be sought in the persons who carry out the law, in ourselves. If the people themselves are reasonable and just, if they enforce the laws with reasonable wisdom instead of making a fetish of the letter of the law, then even under antiquated law existence may be thrifty and flourishing.

When, however, as was recently the case in a sensational murder trial, the law's application results in a monstrosity which obtrudes itself painfully upon the consciousness of every law loving citizen, then it is our duty to ask ourselves conscientiously, Are such monstrosities, such excrescences, the result of inadequate laws, or are we ourselves at fault in the manner in which we apply those laws which we have?

Do our existing laws which govern the plea of insanity in criminal cases constitute in themselves the chief cause for such occurrences, or would it have been possible with these same laws to have built up a more harmonious structure, to have avoided the outcry against the medical expert and therewith against the courts, the laws which govern them and the methods of their administration? Whether or no this could have been done in the individual case here referred to I am not competent to discuss, but I do say that our method of legal procedure in such cases does require earnest investigation in order to ascertain whether it to-day still actually represents that which we desire, that which we as citizens are in duty bound justified in demanding.

My own personal opinion, and I am sure that I do not stand alone herein, is that in many ways we do not get from these laws as they are to-day what we ought to have and what we want. This present writing is undertaken in order to indicate in a general way wherein I believe this defect to exist and in the hope that if a sufficient clamor for a change is raised, such change may ultimately be effected.

\*Read before the New York Neurological Society on December 10, 1907.  
March 3, 1908.

In my opinion the prime change needed is an alteration in the method of giving and taking expert testimony in our courts.

The aim of every criminal procedure is to answer the question whether the accused is guilty. If there exists any reasonable doubt as to such guilt, the verdict must be "not guilty."

This verdict of "not guilty" does not, therefore, without further ado and under all circumstances say that the accused is in reality not guilty, but that the guilt has not been proved. For practical life, and especially so far as the law is concerned, he is then to be placed on a par with the innocent. This is a demand of justice and above all of equity and humanity; but we see that practically it is perfectly reconcilable with even the most ideal conception of criminal procedure that a person who is really guilty may, from lack of evidence, be acquitted. In so far, therefore, the task set for a criminal proceeding is by no means solely the establishment of the truth.

On the other hand, a verdict of "guilty" should be rendered only if the accused is actually guilty; to err is human, but all possible safeguards should be established in order to prevent the occurrence of such an error, and we must strive with all our power to have only him who is really guilty so pronounced. Herein the task of the criminal proceeding is at one with the task of discovering the truth. Inasmuch, however, as it is impossible to say whether a procedure will end with a verdict of "guilty" or "not guilty," each individual case must be conducted from the beginning to the end with but one object—the ascertainment of the truth. To determine the truth is the province of the jury; to point the way to such determination, the province of the court. From the contest between prosecution and defense the truth is to be unraveled, the means at hand for such disentanglement being the evidence, made up of the testimony of witnesses and of experts.

Both witnesses and experts serve only one purpose, the elicitation of the truth; those through truthful evidence of what they have seen, heard, or otherwise observed; these by giving their opinion in accordance with their best knowledge and capability; both, no matter how much they may strive to be accurate and truthful, are subject to error, both are subject to all the influences of human frailty, the measure of each individual as regards the demands which he takes upon himself, his criterion of duty, etc., being measurable by no general standard.

It would be a great gain could we select witnesses in accordance with a certain gauge, but this we cannot do; we must, as a rule, take them as we find them. Not so, however, is it with experts; these may be selected. In fact, they are even now selected, but in an entirely different manner from which I would have it done. While in a certain sense it is anomalous to speak of witnesses for the prosecution and witnesses for the defense, inasmuch as all witnesses, without exception, are supposed to be witnesses for "the truth, the whole truth, and nothing but the truth," and should not allow themselves in testifying to be swayed by the influence which their testimony may have, one way or another, it is certainly monstrous to refer to the *experts* as an expert for the prosecution or an expert for the defense.

The expert is in a way the assistant, the aid, of the jury. In the case of the jury, of course, the ordinary wit-

ness holds, or ought to hold, the same relation, but the expert does so in quite a special sense. Whenever there arises a question in regard to things for the consideration of which the competency of the jurors, in consequence of the lack of special or technical knowledge, is inadequate, experts are needed; where no such extraordinary knowledge is required the jurors will arrive at the truth by means of their own faculties, unaided by extraneous elucidation, without the assistance of experts.

The expert, whose efficiency also culminates in a judgment, should, therefore, place himself as far as possible in the position of a juror, and should draw himself away as far as possible from the position of either the prosecution or the defense.

If, then, as already stated, we are able to select the expert, in contradistinction to the ordinary witness, whom we must take as we find him, with all defects of mind and character which he happens to have, we should do this all the more, because it is his opinion, his judgment, which may be decisive in the formation of the judgment of the jury, or at any rate frequently furnishes this verdict with an important basis. Especially is this so when, in a criminal proceeding, it is a question of the insanity of an individual; here the matter of opinion stands predominant, and the value of this opinion will depend much upon the qualities, educational and otherwise, of the person giving it.

As already indicated, even to-day a certain selection of experts takes place, but in such a manner that the prosecution and the defense enter into direct competition in order to secure whom they consider the most available alienist and to obtain his "opinion" for their own side; of course, always for a fee, which is rarely a small one.

Against this payment of a fee nothing can be said, for the physician is certainly entitled to a remuneration for his time, thought, and knowledge, but it must be clear that the impartiality of expert opinion would, to say the least, in no wise be affected if the payment of such remuneration were left to others than the interested parties. We then have "experts for the prosecution" upon the one side and "experts for the defense" upon the other, and it is accepted that this right to choose and to remunerate an unlimited number of experts should not be curtailed. Yet something must be done, if not to curtail, then at any rate to modify this right, for whereas this competition of the contestants to secure the experts does guarantee that the most "celebrated" specialists will appear as acting "personae dramatis" upon the scene, it does by no means guarantee that the most competent will be called to this honor; and when I speak of competency, I refer not only to scientific attainments, but to that strength of character which will enable them fearlessly to tread the right road, unbiased by any attractions which ambition may present.

Let us be frank with ourselves. Especially in large cities, the eminence of a specialist is only too often dependent upon the accidental, upon extraneous factors which have nothing in common with actual worth, and is often built up through conditions of society, so called, which in its turn is supported upon a foundation made up chiefly of wealth.

Under such circumstances, what are we to expect if the accused is poor? Will these celebrities then

also be obtained to work in his interest? And while upon no field of justice should the success of either party be dependent upon money, certainly in the field of criminal justice the chances of the defense should not be invalidated by poverty! This reason alone should explain why the highest medical authorities call for the abandonment of the present voluntary experts.

We ought, as a permanent institution, to have a class of forensic physicians. This institution, which I am here discussing for psychopathological purposes and which I would premise may be correspondingly developed for all branches of medical jurisprudence, should, in my opinion, be somewhat as follows: These physicians are to be public officials, not city or county, but State officials, so that they may be as independent as possible of local influences. The determining factor in their appointment should be fitness for the specialty which they are to represent. Under no circumstances should their appointment in any way be determined by political influences or considerations.

This exclusion of political influences may be effected by the necessary legal enactments. Most important, however, would be that these safeguards be honestly protected. We must elevate ourselves to a standard which will enable us to realize that there are certain things which stand so high as to be beyond the reach of politics, and among these we must place most prominently the selection of the physicians who are so frequently called upon, by means of their expert opinion, to exert a strong influence upon the honor and the life of their fellow citizens.

This choice is not to be made without discrimination from the general body of physicians, but certain special qualifications should be legally required. Firstly, there should be a certain age limit, before which it is hardly possible to imagine the existence of the requisite professional and general experience. Then a special training should be demanded. This training should start at college with special courses on legal medicine and legal psychopathology, should be followed by clinical psychiatric work in a State hospital, and terminated with a special examination by the State Board of Medical Examiners. The bestowal of a special degree of "physician to the courts," by this board, after proper examination, would ensure the necessary addition to the curriculum by the colleges, and the acquisition of the necessary knowledge by the candidates. The appointment would then be made by the State from the number of successful candidates and should be a life position.

The physician to the courts is obliged at call of the court to give to the court an expert written opinion, and later an expert verbal opinion before the jury. This, however, is, I repeat, only to be done upon request of the court. In the composition of this opinion the expert is neither to receive or accept instruction from any one, his responsibility is one which must be between himself and his own conscience. He should not be prohibited from giving an opinion at private request and for private use, but should be permitted to give an expert opinion for public purposes, and to testify in court only upon call of the court itself. Hence the

physician to the courts will be as little an organ for the defense as a creature of the district attorney. This is the only manner in which the absolute impartiality and the authoritative respect due to the purposes of such an institution can be maintained.

For every piece of work which the physician to the courts does upon call of the courts he should receive a remuneration apportioned in accordance with the difficulties of the individual case and the length of time which he has devoted to its consideration. In addition hereto he should be allowed to occupy a teaching position and to carry on a medical practice in the same manner as is permitted every physician.

By such or similar means will we develop a body of neurological and psychiatric experts who are so in the true sense of the word.

The regulation and supervision of this institution of physician to the courts would, in my opinion, devolve primarily upon the State. Whatever supervision be exercised, the supervising body must by law have the power to render its supervision an active one.

So much about the physicians to the courts, as such. From their number then the court shall, upon motion, or upon its own initiative, select and appoint the experts for each individual case, it, of course, being the province of the court in any special case to appoint as expert any other physician it may desire. Capable judges are competent in any case to say whether the court requires the testimony of experts for its own information, or for the enlightenment of the jury, and also to say who shall be summoned for this expertness.

The expert being appointed, all material which may be of even remote use to him in the formation of a relevant opinion should be placed at his disposal. Only from the entirety of the case can he form an opinion of value. Particularly in questions concerning the mental condition of a person may circumstances which appear irrelevant to a non-medical man be of the greatest importance. Particularly regrettable would be any opposition on the part of the district attorney to the consideration of evidence, for instance, communications which the accused has made to a third party, even where he has the right to object, simply because he believes or fears that such evidence would be of injury to the prosecution.

While it is perfectly true that the relation of the defense to the prosecution is that of antagonism, and that, therefore, each side should and must follow out its individual aim, yet this antagonism on the part of the prosecution should not be overaggressive, for the aim of the prosecution should not be the desire to convict, but the discovery of the truth, the determination of guilt.

It should, therefore, be the duty of the public prosecutor to allow to be brought to light, yes, even himself to bring to light, each and every circumstance which may in any way be of service in determining the mental condition of the accused, without regard to whether these appear to be of service to the prosecution or to the defense. And, furthermore, it should be the province of the court in case either side be one-sided or another be untrue to

this direction, to take upon itself the steps necessary toward bringing out the circumstances which are being concealed or obscured.

For the determination of the mental condition of a person all his acts of commission or omission, his conduct, his mode of life, what he has said, and what he has not said, may be of importance.

Man is an entity. Our comprehension of him will be based upon his development up to the moment of the act which stands in judgment, his personality during the act and immediately after the act, and also upon his life in its subsequent course and his deportment during the investigation. For all this is part of him; all serves for the recognition of his being. The act is a product of his personality; after the act this personality does not lose its entity; the person after the act is no other than the person before the act. To attribute such significance to the act, as to be willing to say: "Everything that was done, said, etc., by him before, during, and immediately after the act, may be admitted in evidence, but everything that occurred subsequently is, so far as possible, to be excluded," is an arbitrary, an unscientific, and an unmedical conception.

The science of medicine cannot be other in a court of law than it is in a sick room, and, therefore, the law must conform to the teachings of science. If, for instance, the accused, while in prison has had various conversations with the physicians, *all* these conversations may be of significance, and it would not be right to admit, let us say, the three first conversations in evidence and not the others; but it may be objected, the accused, who knows the purpose of the conversation, dissembles, simulates, lies, etc., in order to influence and deceive the observer in his favor. True, this may all be so; but *all* without exception, even the fact of simulation, assuming this in a given case to be a fact, serves also for the determination of the being, of the mental state of the accused.

Scientifically there exists no reason why the entire life of the accused after the act should not be admitted as evidence, without limitation. Just as the physician must consider the life before the deed, all individual occurrences before the act, so he must do the same for the life, for the details after the deed. And as the physician must do this in order to arrive at a relevant opinion, so the jury should be permitted to do the same in order to enable it to arrive at a relevant verdict.

The more complete the picture of the accused which can be unfolded to the physicians, the better will it be for the performance of their task, and the court proceedings should be such as to enable them as far as possible to attain this end.

Allowing that the expert should have at his disposal the greatest possible knowledge of the entire case material, in order to be able to give his expert opinion with the greatest possible relevancy, then he should also be permitted to give his opinion as an entity, as a whole. This expert opinion is a scientific achievement, a decision dependent upon so and so many conclusions from so and so many circumstances and particulars of all kind.

The highest scientific demands may be made upon the expert, but no obstacles to the production of sci-

entific work must be placed in his way. Above all, I would demand that he be allowed to deliver his expert opinion quietly and connectedly. Every scientist, artist, or technician in whatsoever field he may be active, if his opinion is desired upon any complicated or difficult matter, would consider it selfevident that he be allowed to expound his opinion in *his* own manner, as he is best able to make it clear to his audience, and that he be given uninterrupted audition. Or if this consideration cannot be given him, he would decline the imputed honor; this he owes to the individuality and thoroughness of science.

Why should the psychiatrist, in this regard, be treated differently in a court of justice than every other scientist is treated outside of the court room; and that he is so treated, no one can deny. Often true equilibristic performances are demanded of him; not three words is he allowed to speak without being interrupted by one side or the other, and questions are all propounded to him piecemeal. Surely, in this way nothing sensible can be produced. Were it not, so to say, a special duty, to serve the courts with expert opinion in cases of criminal actions, no conscientious and selfrespecting psychiatrist could be found who would be willing to participate in such an "obstacle race." And what is the practical result of such proceedings? The expert finally has said all that he wants, or is allowed, to say, in a fragmentary manner, amid endless interruptions and deviations, and frequently amid personal explanations of the most undesirable nature. Therefore, that much is attained, that he is unable to expound his opinion in the proper manner, and that the jury has the greatest difficulty in forging anything serviceable out of this scrap heap. In this way the most simple matter may be complicated in a most unwarrantable manner.

Instead of serving the truth, we are strewing sand in each other's eyes. I can see no reason why the expert, after having been sworn and after giving his qualifications, should not be asked and allowed to expound his opinion of the case in continuity. He is supposed to have been present during the entire trial before the jury, and, therefore, should be perfectly conversant with the subject matter of the action; he can, therefore, of himself, without outside aid, give a clear exposé of his opinion. If there are special points, the understanding of which cannot be expected of a nonjurist, there can be no objection to the necessary instruction being given. We want the truth, we ask him openly and honestly, we explain to him freely and directly the special juristic difficulties, and then he will answer just as openly and honestly, just as freely and directly.

After the expert has finished his exposition in continuity, there probably will yet remain something upon which the defense, the prosecution, and perhaps the court or the jury will, from their point of view, require amplification, explanation or correction. Let each one *now* ask the questions which he would like answered. Herein, what is a matter of course for the court and the jury applies equally to prosecution and defense, namely, that the questions be put simply and honestly with the expressed purpose of arriving at a better understanding of the truth, and that all bythought and hidden design—

technical sophistries for the purpose of confusing the expert—be foregone.

It should not be attempted to make use of the expert in order to show that black is white, or that the one side is the better and the other the worse. Questions of mental disorder, especially those relating to borderline states, are in themselves difficult enough to understand and explain; it is not at all necessary that the subject matter be in addition artificially confused and obscured.

Especially do I believe that the hypothetical form of question is, in general, unnecessary. It is not difficult to deduce, from a correct expert opinion, upon what asserted facts or circumstances it is based, either as a whole or in part. The confirmation of the facts or considerations is a matter for the jury. And is, by implication, contained in their verdict. The expert opinion preceding the verdict, the confirmation of the facts, is, in so far as the expert opinion is concerned, of course only hypothesis.

Wherever a misunderstanding may be possible, this hypothetical character may be emphasized in the form which is given to the opinion. But to attach the entire opinion directly to a hypothetical question does not always make for clarity. Certainly the question should never be given a monstrous form.

I desire now to refer to another aspect regarding the delivery of the opinion by the expert. It is not only to be given coherently, in continuity, but also in language which may be commonly understood. Technical terms, as are used in professional intercourse among physicians, and which are not understood by the average nonphysician, should not be used. The psychiatrist is to use simple expressions and explanations; so far as possible he is to say what he has to say in plain English, and wherever this is not possible he must explain his terms without first being asked to do so. The better qualified, professionally and generally, the expert, the easier will it be for him to develop his ideas in simple language, so that every one with ordinary knowledge and intelligence can follow and understand him. A most peculiar impression is certainly made when, without rhyme or reason, difficult Greek terms are employed, in reference to which, then, questions and responses arise, as in a schoolroom; again a new means of distraction, of confusion—ostensibly, of course, one of enlightenment. For an accurate expert opinion it is furthermore necessary that the expert confine himself to such psychopathological exposition as is required by the case under consideration, and here allow the essential to stand out prominently. Yet how often do we witness an expert going through almost the entire field of insanity, with references to all possible and impossible allied forms of disorder.

*This should not be.* And this will be avoided, if, in accordance with the demands already made, the psychiatric expert be really treated as a man of science and be allowed to solve his task coherently and without interruption.

Then he can and will of himself keep to the point and endeavor to instruct the jury in simple, inartificial, truthful manner, instead of blinding them with sophistical fireworks.

The ideal in expert testimony would be still more approximated if the expert, at as early a stage in the proceedings as possible, was permitted the great-

est possible insight into the details and entirety of the case; which means that he be not drawn into the case, as is now done, just at, or shortly before, the trial itself. The proceedings before the jury are certainly the essential, but no lawyer, whether he be for the prosecution or for the defense, and no court would show any special predilection for occupying themselves with the case only when the proceedings before the jury are begun.

The earlier the stage at which the expert approaches the case, the deeper will be his understandings of it, and the sooner will he become equal to the task which has been set for him. For this reason, in every case in which there is a question of mental disorder, the expert should be called in from the very beginning. Time spent by him in his own study and in the cell of the accused will be well applied, and when, thus fortified, he is present at the trial itself, he will be able in a brief exposition to furnish the best that could be demanded of a medical expert, and will be able to instruct the jury with the greatest imaginable certainty. In all cases in which it is a question of the insanity of the accused, not only at the time of the proceedings, but particularly at the time of the commission of the deed, it would be of great importance, not only to have him examined by a commission aided by experts, but, in the interest of personal liberty and acceleration of the proceedings, to commit him for observation during a limited time into an insane asylum. In clear cases this would not be necessary, in doubtful ones, however, of inestimable value.

The scientifically organized and medically supervised insane asylum is the only proper place for such observation. That, of course, a State asylum is the only one which could here be considered, must from the nature of the proceedings be clear. The maximum time of internement for the purpose of observation could in each case be determined by the court; yet a general maximum which should not be transgressed, say, perhaps six weeks, which would, in my opinion, be ample even in the most difficult cases, could be established by law. Yes, it is even a question in my mind whether such internement could not be permissible even before the findings of the grand jury—that is, before any formal indictment has taken place. The results of such observation might then occasionally be such that the grand jury would decline to indict. Then the mental rack of the proceedings could be spared the patient, treatment be started earlier, his rights of citizenship sooner safeguarded, his family protected against unspeakable suffering, and last, but not least, the mass of sensation lusting members of "society" be robbed of one victim of their ignoble curiosity.

I have already said what seems to me to be a self-evident truth, that a surplus of experts acts as an injury to a case. From the moment that the people have gained actual confidence in the experts themselves and in their mode of action in criminal cases, and have accustomed themselves to look upon and to appreciate the expert as a leader toward truth, then the endeavor of the parties to have as many experts as possible will cease of itself. More attention will be given to the qualities of the experts than to their number. The law already to-day empowers the court to reject superfluous evidence. If the expert

system as I have expounded it is once established and employed, the judge will, even less than at present, have any reason to fear that, through the rejection of such superfluous expert testimony, the proceedings may be successfully attacked. And what I have said here about the rejection of superfluous experts applies also to the rejection of superfluous questions asked of the experts. If the expert has given his opinion coherently and exhaustively, and has supplemented it, so far as necessary, by answers to the questions asked by the two sides, by the judge, and by the jury, he can, with a clear conscience, decline to answer any further questions, and the judge will support him in this refusal, in order that the court procedure be not turned into a farce. But, as stated, it is my firm conviction that no side with any selfrespect will endeavor, by means of unnecessary questioning, to make a caricature of a serious scientific opinion, which has done justice to all of the circumstances bearing upon the case. Far be it from my desire to unwarrantably limit the right and duty of questioning and cross questioning. I desire only that the misuse of this right and duty be opposed, opposed not only in open court in each individual case, but as a matter of principle through public opinion. All of which clearly appears justified by the fact that the refusal by the court to allow really immaterial questions can in no wise be considered among the causes for appeal. Herein, therefore, no change of the existing law is in any way required.

It is merely a question of the manner of administration. On the other hand, I would lay stress upon the following innovation. At any stage of a criminal procedure, the court, whether upon motion of either side or upon its own initiative, should be permitted to appoint one or more experts. In which case the prosecution, regarding its task as it should be regarded, viz., the ascertainment of the truth, would very rarely feel called upon to introduce additional experts. The defense also will, in the majority of cases, relying upon the personality, capability, and integrity of the expert appointed by the court, be content with such appointment, knowing full well that its own interests will be completely protected.

I do not conceal from myself that this proposition will in the beginning meet with manifold energetic opposition. This opposition is voiced by a judge of the Supreme Court of New York with the words: "This idea of official witnesses is totally opposed to all ideas of American and English jurisprudence. It would be a departure in a direction contrary to the spirit that has given rise to our free institutions. It may be an improvement, but it is radically different; and we should consider that before we determine as to what is the true solution of the problem."

But this proposal tends toward placing the experts in every way above party lines; it is directly interwoven with the high conception which we all have of the duties of an expert, and which I would like to see adopted and practically carried out, even "if the ideas of American and English jurisprudence" must adapt themselves to the progress of the times.

When the experts make such high demands upon themselves and the people will have accustomed

themselves to see in the expert the real scientific expert, instead of the medical counsel for the defense or for the prosecution, then this proposition will lose all appearance of doubtfulness, and then will, as I hope, the appointment of the expert by the court, whether upon motion of the prosecution or of the defense, or upon its own initiative, become the rule.

Not one of the least important advantages which such a procedure would carry with it would be that the most capable experts would be available, even in proceedings against the poor and the destitute. I would advocate still one more change in our existing criminal law, which, as it now stands, reacts deleteriously upon our entire expert system. I refer to the part of our penal code, derived from the old English law, which still exists among us, but which certain States of the Union, especially certain New England States, have long ago altered. This is our right and wrong test of insanity. As is well known our penal code requires for the irresponsibility of the accused such a defect of reason that the accused, in consequence of this defect, at the time of the execution of the act, did not know the nature or quality of the act he was doing, or did not know that the act was wrong. According to this no other state of mental disorder suffices for the assumption of irresponsibility. But this is one sided and by no manner of means just toward the requirements of medical science.

Scarcely any textbook of insanity, no matter in what country it is published, can be opened without finding therein, as a clear and indisputable, practically proved fact, that there exist a certain number of mental disorders in which the intellect is not so influenced that the patient did not know the nature or the quality of his acts, or did not know what was right and what was wrong, but in which, nevertheless—in full knowledge of the nature of his action or of the wrongfulness of the act—on account of a pathologically altered will or emotion, he was not able to conform his actions to the dictates of his intellect; in other words, that it is not the knowledge of the nature of the act or of the right or of the wrong—in relation to the concrete act—that it is not the intellect which is of decisive importance, but much more the question whether the person, in consequence of pathological disorder, was limited or inhibited in the use of his will.

Most nations have since a long time so altered their criminal law that it now conforms to this fact of medical science; only not in England and in single states of English law. Our New York law has, up to the present time, in opposition to all scientific progress, held on to this peculiarity of the old English law; therefore, to-day, still possesses antiquated English law. Every expert in insanity, lawyer or physician, knows this to be a fact. Yet what is the result of the application of this law in our criminal proceedings?

If the accused at the time of the commission of the act was disordered in intellect to such an extent that he could not recognize the nature of his act, or could not distinguish between right and wrong in relation to it, then, of course, according to our law, the expert encounters no difficulty whatsoever. He simply gives his opinion that the ac-

cused, as a result of his disease, was unable to recognize the nature of his act and could not distinguish between right and wrong.

But how about the other cases in which the patient is able to recognize the nature of his acts, and is able to distinguish between right and wrong, yet in consequence of disease is deprived of his freedom of will and thus is prevented to act accordingly? Here, then, the conscientious expert must declare it as his opinion that the accused, who, under the influence of a disordered mind, was deprived of his freedom of decision, is, in the sense of the law, *not insane*. For the honest scientist truly a position which could not be worse. Under such conditions the temptations for some may be strong, by means of subterfuges, by means of all kinds of dissertation upon all possible and impossible forms of insanity and symptoms, to rescue justice from the hardship of the law.

It has seemed to me necessary to go into this question on account of the close relationship which exists between it and the attitude of the expert in court.

In conclusion I would say that my essay upon the system of expert evidence in criminal proceedings by no means seeks to introduce a doubtful or dangerous experiment into our legal life. The recommendations here made are those which, in other places, so particularly in Germany, are in action, are in accordance with general conviction of the people, and have proven themselves worthy.

They could be organically woven into our criminal proceedings without creating any difficulty or causing any disturbance. Thus, the privileges of the judge would be somewhat extended, but the fundamental law which governs our courts, that the trial of the case belongs to the opposing parties, while only the general direction lies with the court, would be little, certainly not materially, interfered with; nor can I see that, that "*nole me tangere*" of the lawyers, "the law of evidence," is in any way hereby affected.

## THE NEED OF CARE FOR THE CONVALESCENT FROM THE HOSPITAL STANDPOINT.\*

By S. T. ARMSTRONG, M. D.,  
New York.

In 1899 the surgeon in charge of a general hospital in Manila deemed it inadvisable to have his convalescent soldiers eat their meals in the wards, and in conformity with military procedure forwarded a request to the commanding general for authority to have a messhall constructed. The request was returned disapproved, with the endorsement that soldiers who were well enough to go to a messhall were well enough to be out on the firing line. The general's attitude impresses one as harsh, unnecessary, and subject to condemnation; and yet the attitude of many hospitals to the convalescent is similar, though it is true that the motives that prompted the general referred to were not the same as those that have op-

erated in civil hospitals, because the latter have had to provide the greatest amount of relief to the greatest number, and the convalescent has had to be discharged to make room for the acutely ill or for those in need of operative interference.

In many ways a hospital is a manufactory of health, a repair shop for mankind; and like all manufacturing establishments its efficiency is based on a complexity of organization that has carefully considered the relation of means to ends in accordance with the class of patients treated. But, unlike a factory in which certain mechanical, physical, or chemical procedures will entail certain definite products, a hospital cannot by certain similar procedures, in apparently similar morbid conditions, produce health. Many patients attain a normal condition in an average time, but there are others affected by similar diseases who, at the expiration of the average time, are only more or less advanced in convalescence. Such patients cannot well be kept, until they have regained their health, in a hospital intended for an acute service, without detriment to the purposes of the institution and to their own convalescence.

Many centuries ago Plato submitted the postulate "that in all well ordered states every individual has an occupation to which he must attend, and has therefore no leisure to spend in continually being ill. This we remark in the case of the artisan, but, ludicrously enough, do not apply the same rule to people of the richer sort." He goes on to say that "when a carpenter is ill he asks the physician for a rough and ready cure; an emetic or a purge or a cautery or the knife—these are his remedies. And if some one prescribes for him a course of dietetics, and tells him that he must swathe and swaddle his head, and all that sort of thing, he replies at once that he has no time to be ill, and that he sees no good in a life which is spent in nursing his disease to the neglect of his customary employment; and therefore bidding good bye to this sort of physician, he resumes his ordinary habits, and either gets well and lives and does his business, or, if his constitution fails, he dies, and has no more trouble."

While the hospital staff may not always keep in mind that their poor patients have no time to be sick, in general most measures are adopted that will carry the patient as expeditiously as possible through to convalescence. Then the patient is discharged to his home, or permitted to continue in the ward, with such cursory supervision as seems advisable until he asks for his discharge, or it is apparent that he has regained his usual efficiency, or it is evident that the latter cannot be regained. Either of these latter methods is inadvisable and uneconomic. To send a convalescent patient home is to relegate him frequently to an undesirable environment, to inadequate or improper food supply, to the ministrations of injudicious relatives or friends, to premature work to earn his support, and each or all of these in the condition of lessened resistance associated with convalescence may divert the latter into a state of permanent invalidism.

To keep such a patient in a hospital intended for acute diseases is an unnecessary tax on the higher per diem cost of maintenance in such an institution, and deprives the patient of those measures of hydrotherapy, mechanical therapy, electrotherapy, and aera-

\*Read before the Section on Public Health, New York Academy of Medicine, January 14, 1908.

therapy which should be particular features of hospitals for the care of convalescents and which are rarely available in general hospitals.

In 1904 the Census Bureau made an important investigation of the hospitals in the United States and found that there were 220 public, 831 private, and 442 ecclesiastical institutions, a total of 1,493 hospitals. At an expense of \$28,200,866 these hospitals treated 1,064,512 patients, of whom 71,530 were in the hospitals at the end of the year, and therefore 992,982 patients were discharged or died. How many of these patients were discharged in a state in which they needed further treatment? The percentage may be approximated from the experiences of Bellevue and Allied Hospitals, which in 1906 discharged 31,334 patients, of whom 13,825, or 44.1 per cent., were discharged improved; that is, they were not in a condition to resume their usual avocations.

If, from necessity, they did resume their customary work, it was done with a more or less impaired physique, and consequently with proportional diminution in efficiency. Let it be granted that the four city hospitals referred to have an exceptional clientele in the destitute poor of New York City, that all other hospitals transfer to them those patients whose diseases entail prolonged convalescence or are incurable, and that in turn Bellevue and Allied Hospitals pass these patients on to the hospitals of the Department of Charities, still it is believed to be a moderate statement that more than thirty per cent. of the patients discharged from hospitals in this country are in need of further treatment. This would mean that in 1904 about 300,000 patients had to be discharged who needed hospital care longer.

Great Britain, France, Germany, and Switzerland have recognized the importance of the transfer of convalescent patients from city to country hospitals. Indeed, in Great Britain there are 278 such institutions, and thirteen of the London hospitals have their own convalescent homes. In this country there is a good example in the Massachusetts General Hospital, which has 261 beds, and which established in 1882, at Waverly, a convalescent home containing thirty-one beds, at a cost of \$50,000. These institutions should give a fair idea of what such a home may accomplish. In 1906 the hospital treated 5,075 and the home 519 patients; the average number of patients in the hospital was 272 and in the home 23; the average number of days each patient was in the hospital was 19.6, and in the home was 16.2. A little more than ten per cent. of the patients were sent to the convalescent home, and the latter was not used to its full capacity.

English hospitals find greater need for this convalescent relief. The East London Hospital for Children, having 109 beds and treating 1,587 patients, has the Princess Mary Convalescent Home with twenty-eight beds, and treated 317 patients. The French Hospital, that has seventy beds and treated 790 patients, has a convalescent home at Brighton with sixteen beds, and treated 180 patients. Victoria Hospital for Children, with 104 beds and treating 962 patients, has a convalescent home at Broadstairs with fifty beds and treated 663 patients. Middlesex Hospital has 343 beds and treated 3,147 patients, and its convalescent home at the seashore

has sixty-one beds and treated 878 patients. Charging Cross Hospital, with 187 beds and 2,465 patients treated, has a convalescent home of fifty beds, which treated 470 patients. These figures might be continued and would show an accommodation of about twenty per cent. of the hospital population. And it is believed that the number that would be helped would be greater if it were not for the question of finance.

From the cost of administration standpoint it is materially more advantageous to provide convalescent hospitals. In the latter the cost per patient in Great Britain is about one half of what it is in a general hospital; and in the Massachusetts General Hospital, while the per diem cost in 1906 was \$2.062, it was \$1.302 in the convalescent home.

From the standpoint of cost of construction, while the urban hospital of the present day type will cost from \$3,000 to \$5,000 a bed, the convalescent hospital can well be built at a cost of from \$1,000 to \$1,500 a bed.

One of the greatest difficulties that would be met with in applying the principle of treatment in a convalescent hospital to patients whose preliminary treatment was in a general hospital would be the opposition of the patient or of his relatives and friends to his transfer. The administration of the institution would be subjected to political, financial, social, and other pressure to exempt certain patients from the application of the rule. There should be in a free hospital a nurse in charge of convalescent relief work who should visit each new patient admitted to the hospital, and by tactful inquiry she should learn the general situation of the individual, and whether there were dependents left at home who should be looked after by some organization or volunteer worker. Her professional training and knowledge of the methods of the visiting physician or surgeon would indicate those who should be transferred to the convalescent hospital, and she should represent to them the advantages in ultimate and perhaps complete cure that would be gained by a sojourn in such an institution.

Establishments for convalescents should be located in accessible places that could be reached by a minimum expenditure for car fare, and that would not exhaust the patient by fatigue when transferred. Reasonable provision should be made for the care of those not distinctly convalescents, but who are dependent on the patient, as in the case of mother and child.

The following conclusions are submitted:

1. The purpose of hospital treatment should be to further as expeditiously as possible the return of the patient to a condition of physical efficiency.
2. Proper hospital treatment for convalescents should be provided to accomplish this end.
3. For economic reasons the treatment of convalescence should be separated from that of acute conditions. But for the same reasons a hospital for convalescents may be associated with one to treat chronic diseases.
4. Urban accommodation for convalescents is impracticable and undesirable, and accessible suburban sites should be selected to locate hospitals for convalescents.
5. Convalescent hospitals should be constructed at

moderate cost; they should provide for patients likely to require a long as well as a short duration of convalescence; they should be equipped with all apparatus that will further restoration of tissues and organs to normal; the patients should be subjected to proper medical supervision.

6. A committee or society to advocate convalescent hospitals should be formed to cooperate with a charity organization society, or association for improving the condition of the poor, or State board of charities. Such a society in England has accomplished good results.

144 EAST THIRTY-SEVENTH STREET.

## A BRIEF STUDY OF THE PROSTATE WITH REFERENCE TO THE CURABILITY OF GONORRHOEA.\*

By A. L. WOLBARST, M. D.,  
New York,

Attending Genitourinary Surgeon, Beth Israel Hospital and West Side German Dispensaries; Professor of Genitourinary Diseases, New York School of Clinical Medicine.

It is surely not necessary at this late date to quote from the extensive literature on the subject, in order to demonstrate that the crucial point in any discussion of the curability of gonorrhœa in the male, is to be found in the presence or absence of gonococci in the prostate and its annexa. Experience has taught us that the genital portion of the genitourinary tract is the most resistant to treatment, and the last part of the affected region to recover. It, therefore, goes without saying that although the urethra proper may be entirely cured of the gonorrheal process, the prostate and annexa may still be infected, and that from time to time outbreaks will occur which owe their being to the latent gonococci which have not been dislodged by treatment, from their deep seated hiding places in the prostate and vesicles.

That the gonococcus may remain dormant in the prostate and awaken months and even years after the initial infection, has been clearly shown by the studies of too many careful observers to admit of any serious doubt. Nevertheless, in spite of this well known fact, and perhaps just because it is so plainly obvious, comparatively slight attention is usually paid to this subject in actual practice, and it is the purpose of this brief paper to direct attention to this oft neglected but highly important element in the study of gonorrhœa.

We must confess that all of us are not yet altogether agreed on what constitutes a cure in gonorrhœa. We have on the one hand the busy general practitioner, always glad to get rid of his "clap" cases, and who discharges his patients as soon as the urine becomes clear and there is no discharge at the meatus; on the other hand we have the physician-specialist who goes to the other extreme and cries at every breath "once gonococci, always gonococci." These men represent the great divergence of opinion which characterizes medical men in the matter of the curability of male gonorrhœa. The one man declares that "clap" is nothing worse than a slight

cold, and is just as easily cured; the man at the other extreme regards gonorrhœa as a hopelessly incurable disease. Who is right?

It is certainly true that many cases of gonorrhœa do get well in remarkably short time, with or without treatment, and often in spite of treatment. It is also true that a considerable number of men who have been infected with the gonococcus, never get rid of their disease entirely. So that both extremists may justify their attitude in the light of experience. My personal preference is to take the happy medium and say that although gonorrhœa in the male is often cured entirely, and sometimes spontaneously, it very often remains uncured, in spite of the most enlightened and skilful treatment obtainable. And I would furthermore declare no case cured until the infectious element, the gonococcus, has been entirely eliminated from every portion of the genitourinary tract. So long as a single living gonococcus remains hidden in any part of this tract the patient is in danger of an outbreak of his old disease months or even years after all traces of his original attack have passed off.

It is customary with many practitioners to examine the freshly passed urine of a patient seeking a verdict of "cured," and if it appears clear and sparkling, and if in addition they find no gonococci in it, they send the man on his way home rejoicing that he is well and cured. Yet I believe it is more than probable that every man who has had a posterior infection, even if his urine is clear as crystal, has a prostate that is to a greater or less degree choked up with gonococci, ready at any moment to spring into activity and demonstrate their presence by unmistakable symptoms.

Several years ago my attention was attracted to a large number of cases of chronic and recurrent gonorrhœa that came under my notice, all of them presenting a common trinity of symptoms, a slight or moderate discharge, especially in the morning, a large and tender prostate, and a history of frequent recurrences under excesses of venery and drink. Microscopical examination of the urine or discharge often showed the utter absence of gonococci, but with very few exceptions, the massaged urine or, better still, the expressed secretion of the prostate nearly always showed the presence of gonococci. This observation led to a detailed study of fifty-five cases and they furnish convincing proof to my mind, if such proof were necessary, that it is the deep seated gonococci in the prostate and vesicles that we have to get rid of before we can hope for a lasting cure of gonorrhœa. A few typical cases will illustrate this point very nicely.

CASE I. E. W., aged 35 years, a stock broker, married, no children. Appeared for treatment because of the presence of a moderate, slightly mucous, discharge, and because of a large, tender prostate. He had been married for three years and had one child. He had been treated for gonorrhœa several times, and had been cured of the disease each time. He had no history of gonorrhœa, but he had had several outbreaks of gonorrhœa which were quite customary with him.

Physical Examination. Temperature 98.6, pulse 72, blood pressure 110/70. Prostate 4x5x3 cm., firm, tender, and slightly enlarged. Urethra normal. Urine clear, but on standing it became cloudy. Microscopical examination of the urine showed no gonococci. Microscopical examination of the expressed secretion of the prostate showed many gonococci. Treatment. This attack had been followed with strict and painful continence. He had been treated with salicylates, but he could recall about fifteen distinct attacks. Treatment. He was given a course of treatment with penicillin. His prostate was never examined or treated.

\*Read before the American Urological Association at Atlantic City, N. J., 1927.

Examination: The discharge contained pus and epithelial cells, numerous gonococci (gram negative). First urine passed was cloudy, with pus and many shreds; second urine, clear; massaged urine was very cloudy. Microscopically, the first urine contained few gonococci; second urine none; massaged urine very many. The irrigation test showed the presence of posterior urethritis. The prostate was fairly large and tender to the touch. Vesicles the same. No stricture appreciable.

Subsequent History: Under local and internal treatment the discharge quickly subsided and disappeared, the urine cleared up within ten days, and the freshly passed morning urine showed the complete absence of gonococci. On February 2d the patient expressed himself as feeling entirely cured. With the present study in mind, I had him call early the next morning, and he passed two ounces of over night urine in a sterile flask (glass 1). This was perfectly clear; I then massaged his prostate and vesicles vigorously, and he passed two ounces of very cloudy urine in another flask (glass 2). Microscopical examination of the urine gave this result: Glass 1, negative as to gonococci; glass 2, positive; also much pus and epithelia. These examinations were made at intervals of three or four days for three weeks with the same result: Glass 1, negative; glass 2, positive. Meanwhile treatment was continually being directed to the prostate and vesicles, with the result that in April (nearly four months after treatment was begun) the massaged secretion for the first time gave a negative result. Thereafter the result wavered from negative to positive and vice versa, until a month later (May) I succeeded in getting seven consecutive negative results, at intervals of one week.

The man has resumed his marital relations, he drinks as usual, and has had no recurrence of his old attacks. Once a month he comes for examination, and throughout the entire year I have been unable to discover any gonococci in the massaged urines or in the expressed secretion from the prostate. I consider this man cured.

CASE II.—A. A. A., cigarmaker, age twenty-three, unmarried, presented himself for treatment on May 1, 1906, with a moderate discharge, and symptoms of chronic cystitis. Duration one year. First attack was treated by various physicians, but never declared cured. Prostate was never examined or treated.

Examination: The discharge contained gonococci (gram negative) in moderate amount. Urine passed in three glasses were all cloudy, and all contained gonococci. Examination made the next day by the writer's three glass catheter test<sup>1</sup> revealed an anteroposterior urethritis and chronic cystitis. Prostate large, hard, and tender in certain spots. Vesicles moderately congested. No stricture appreciable.

Subsequent History: After two months of treatment directed at the bladder, prostate, and vesicles, the urine became quite clear, but not entirely free from shreds and mucus. A series of examinations similar to that described in Case I was gone through, with the same result, viz., the morning urine passed by the patient was free from gonococci; the prostatic secretion contained numerous gonococci.

This man has been under constant observation and treatment just one year, at this writing. His over night urine has been clear and free from gonococci since July, 1906; but it is only since March, 1907, that his massaged secretion gives an occasional negative report. When I can succeed in getting from seven to ten negative reports in succession I shall feel justified in concluding that this man is as thoroughly cured as, with our present knowledge, it is possible to be.

CASE III.—E. K. J., aged twenty-eight, unmarried, lawyer, presented himself for treatment on May 1, 1906, with moderate amount of discharge, cloudy urine, and some pain in passing it.

Previous History: First attack, September, 1900. Was treated six weeks and pronounced cured. Since that time has had repeated attacks at rather frequent intervals, especially after sexual excesses. Prostate had never been examined.

Examination: The discharge contained gonococci. The Jadassohn-Goldenberg irrigation test showed the presence

of a chronic anteroposterior urethritis; both urines were cloudy and loaded with gonococci (gram negative). Prostate was large, hard, and tender, vesicles the same. No stricture.

Subsequent History: After four weeks of treatment the urine became clear and the gonococci were not found after repeated examinations. The massaged prostatic secretion, however, gave a positive finding until September (four months after treatment was begun), since which time repeated examinations have given uniformly negative results. The man has since married, and recent examination failed to reveal the presence of gonococci.

These three selected cases out of fifty-five thus studied, illustrate the point I wish to emphasize in this paper, namely, that the mere presence of pus and gonococci in the urine passed by the patient is no criterion as to whether or not he may consider himself cured; the important point to determine is whether or not the prostate has been emptied of the gonococci that infested it. And this can only be determined by the methods described—that is, vigorous massage of the prostate and annexa, and a careful examination of the expression urine voided, or, better still, the secretion obtained by massage and stripping.

Without wishing to burden this paper with details of the fifty-five cases studied, a few general figures and conclusions might not be out of place.

Duration of disease before coming under observation:

6 weeks to 6 months.....	24 cases
6 months to one year.....	15 cases
1 year to three years (never well).....	7 cases
3 years to 10 years (frequent recurrences).....	5 cases
12, 15, 19, 26 years (frequent recurrences, of each one case).....	4 cases

Of the fifty-five cases studied fifteen patients are still under treatment and observation because of the occasional positive finding of gonococci in the expressed secretion. Forty have, therefore, been declared cured. Of these forty patients the duration of treatment before the disappearance of the gonococci from the morning urine, passed by the patient, varied from ten days to eleven weeks; from the massaged prostatic secretion in the same patients from nine weeks to ten months. While exact figures cannot be given, these cases show that the longer the duration of the infection, the longer it takes to get the gonococci out of the prostate and annexa.

### Conclusions.

1. The so called "incurable" and "recurrent" cases of gonorrhoea are those in which the gonococci remain latent in the prostate and annexa.

2. Every case of chronic gonorrhoea in the male should be thoroughly examined for gonococci in the prostate and annexa.

3. The morning urine passed by the patient may or may not contain gonococci; the massaged urine passed immediately after, or, better still, if it can be obtained, the expressed secretion of the prostate, will most always give a positive finding.

4. The urine passed by the patient may be clear and sparkling; yet the massaged urine may be full of pus, and epithelia, which are loaded with gonococci.

5. There is no direct relationship between the urine clearing up and the disappearance of gonococci from the prostate.

6. Five examinations of the massaged urine may give a negative result. The sixth may give a reverse verdict. Here persistence is a cardinal virtue.

7. Before a patient can be declared "cured" and marriage sanctioned, he should be put on the customary tests, and in addition, the massaged prostatic secretion should be examined at weekly intervals until at least six consecutive negative findings result. Thereafter for at least a year, a monthly examination of the same kind should be made, so as to make assurance doubly sure.

105 EAST NINETEENTH STREET.

## THE OPERATIVE TENDENCIES IN MODERN OBSTETRICS.\*

BY ARTHUR STEIN, M. D.,  
New York.

A study of the development of the art and science of midwifery during the many centuries up to modern times shows a decided neglect in the direction of the evolution of the operative field. In spite of the fact that operative obstetrics originally was taught by surgeons and was regarded as a part of surgery, this branch of medicine drifted far away from its mother science. In the second half of the last century, while great strides were being made in operative gynecology, chiefly under the guidance and cooperation of prominent surgeons such as Billroth, Simon, Czerny, and Mikulicz, the opinion still prevailed that operative obstetrics had reached its full development. Only when modern gynecologists began to apply the knowledge they had acquired in the diagnosis and treatment of the female genital organs to the functional activity during the period of gestation, did operations become more frequent in obstetrics. And even then the advances were few, for the gynecologists were still too wrapped up in their own subject, so that operative obstetrics only began to keep pace with the advances in gynecology during the last two decades.

Beginning with Säger's and Kehrer's improved methods of performing an abdominal Cesarean section and the introduction of Porro's operation, we gradually reach a period in which operative obstetrics began to advance along lines hitherto unknown. Briefly stated, the sentence: "Every perforation of a living child is a crime," covers the operative tendencies of this period, in which the life of the child was given as much consideration as that of the mother. All the more recent operations were devised to deliver a living child whenever possible without imperiling the life of the mother. These operations can be divided into two classes, those involving the maternal soft parts and those involving the bony pelvis.

At the International Congress of Medicine held in Berlin in 1890 Bossi and Dührssen, independently of each other, suggested an operation on the maternal soft parts which made it possible to empty the uterus in a very short time, with the underlying purpose of delivering the mother of a living child without thereby imperiling her life; the former trying to attain this end by a bloodless, the latter by a cutaneous operation. Bossi's method was at first adopted with enthusiasm by almost every one, only to be gradu-

ally supplanted by operations based on more scientific principles.

Believing that the bloodless methods of dilating the cervix then in vogue (laminaria, bags, bougies, etc.) did not suffice in urgent cases, because they required too much time, Bossi constructed a dilator with which he asserted that it was possible during pregnancy or labor to dilate an unobliterated cervical canal to such an extent, in from fifteen to thirty minutes, that all major operations like forceps delivery, version, or extraction could be performed without further delay. The indications set down by Bossi for his method of dilatation included all cases in which a rapid delivery was desired in the interest of the mother or child, thus in cases of eclampsia, cardiac disease without compensation, grave diseases of the respiratory tract, premature separation of the normally or abnormally situated placenta, rigid external os, prolapse of the cord, pernicious anemia, prolonged labor, and in cases with signs of decomposition of the uterine contents or of beginning infection; furthermore, he considered it a new method of inducing labor. When we consider that the older methods employed to dilate the cervical canal really required many hours or even days before complete dilatation was accomplished, we can readily understand the great advantages of a rapid method of dilatation followed by immediate delivery. Bossi's procedure was therefore very tempting, for it seemed to satisfy a long felt want; its advantages were, however, accompanied by such great disadvantages that no conscientious obstetrician could fail to weigh the latter in his mind before employing the method.

The dilator whose use was chiefly advocated by Leopold and his school consists of four steel branches which can be separated eight or ten centimetres from one another, through the medium of a screw, after the closed instrument has been inserted into the cervix. The mode of action of the instrument depends upon whether the cervical canal is still entirely closed, or whether it is wholly obliterated, with only an undilated external os. In the latter case, provided the condition of the soft parts is normal, the instrument will, as a rule, dilate the os rapidly, easily, and without danger. Even Dührssen, its most zealous opponent, admits this when he says: "In a number of cases with obliterated cervical canal the instrument can dilate the closed or partly dilated external os of a primipara to such an extent as to make the extraction of a living child possible." In other cases of this category it is at times impossible to dilate the external os, or the dilatation takes place at the expense of cervical tears. If this occurs in cases with an obliterated cervical canal, how must the instrument act in those cases for which it was originally recommended, i. e., those where there is no dilatation of the cervical canal. As a matter of fact, the most extensive and uncontrollable injuries, with their disagreeable after-effects, have taken place in these latter cases. Wyder in von Winkel's *Handbuch der Geburtshilfe* says: "There exists the danger of causing more or less extensive tears of the lower uterine segment, which may enlarge during subsequent delivery. A fact easily understood, as Bossi's instrument does not dilate the cervical canal in the physiological manner, but only pulls its walls apart, the stretching taking place from the points where

\*Read before the German Medical Association at the 50th Year Meeting, 1907.

the four branches of the dilator come in contact with the cervix, and not equally in all directions. It need hardly be mentioned that the cervical tissue at these four points is subject to being crushed, and that the intervening tissue which is put on a stretch is in danger of being torn." Numerous cases have been reported in which extensive tears occurred in just this manner, among them those of Knapp, Wagner, and Lederer. It does not come within the scope of this article to describe in detail the injuries observed in their cases, but the general impression gleaned from their reports and also my own experiences, which were similar to von Bardeleben's at the Charité in Berlin, led me to believe that in performing a purely mechanical dilatation with Bossi's instrument we do not properly consider the dynamic forces. I furthermore doubt whether Bossi is right when he maintains that it is possible to stimulate the dynamic forces of the uterus during the short time of dilating the cervix with his instrument. Other disadvantages of his method are, an increased liability to infection and the danger of atonic post partum hæmorrhage, to which Schatz especially draws attention. Endometritis and inflammations of the parametria as results of deep cervical tears must also be considered when we discuss the value of Bossi's method. As was said before, the procedure is connected with little danger when the cervical canal is entirely obliterated, as the injuries then involve only the external os, but under such conditions the use of the dilator is unnecessary, as bags produce a more complete dilatation when the os yields easily, and as incisions are more reliable when the os is rigid. The only way to avoid the dangers and disagreeable after effects of Bossi's bloodless method of dilatation is to abandon it. This we can all the more readily do since in Dührssen's cutting operation we possess a method of dilatation which enjoys all the advantages of the Bossi method, while it is free from its disadvantages.

Dührssen first described his method under the name "deep cervical incisions," and finally after improvements in technique changed it to "vaginal Cesarean section," under which name it has attained an undisputed place among modern obstetrical operations. He showed how, by means of four deep cervical incisions, combined with episiotomy (*Scheiden-Dammnincision*) if the vagina was small, it was possible to deliver even a primipara with closed cervical canal of a living child, provided, however, that the supravaginal portion of the cervical canal was obliterated. This proviso became unnecessary in the vaginal Cesarean section, as the lower uterine segment was now included in the field of operation. *The introduction of this operation represented a real advance in modern operative obstetrics*, for it was now possible, during pregnancy or labor, to bring about an immediate delivery if the condition of mother or child demanded it, even when no part of the cervical canal was obliterated, and then without imperiling the life of the mother; the operation was therefore also a means by which an abdominal Cesarean section could be avoided. This operation in my belief is also destined to take the place of the classical Cesarean section in the dying woman. In this case we must operate in the interest of the child.

While this operation possesses only one contraindication, i. e., a true conjugate below seven or eight centimetres, it possesses very important advantages over abdominal Cesarean section; in the first place, the peritonæum remains unopened, so that it can be carried out in infected cases, when the abdominal method is contraindicated on account of the danger of general peritonitis; secondly, it is not held in such horror by the laity, who give their consent to a vaginal operation much more readily than to an abdominal one.

This brings up the much discussed question as to whether the operation should be performed in a private house. Cases have been reported in which a general practitioner successfully performed it in private with the assistance of a midwife, and often not under desirable surroundings. Of course, it is understood that it must be done only by a physician, who is capable of making a correct diagnosis and who has had some surgical training; in his hands the operation is easy and should be successful if he operates according to Dührssen's rules.

The latter's method, briefly stated, is the following: The cervix is grasped with two bullet forceps and a sagittal incision made through its posterior lip, extending for four centimetres into the posterior vaginal fornix, when the fold of peritonæum, known as Douglas's pouch, is separated from the posterior wall of cervix and uterus, by blunt dissection. Then the mucous membrane of the anterior vaginal wall is divided from the urethra downwards, the bladder is pushed back (which is a very easy matter under normal conditions in pregnancy), and the anterior lip of the cervix is divided sagittally. Having exposed the anterior and posterior uterine walls the cervical incisions are extended through them for six centimetres, the opening thus made must admit a fist before the extraction of the foetus is begun. If there is an atonic hæmorrhage the placenta must be manually extracted and the uterus packed, but ordinarily the third stage may take its normal course, after which the wounds are closed with interrupted sutures, and a small gauze drain inserted into the antecervical and retrocervical space. To my mind the modifications of Bumm, who divides only the anterior cervical and uterine wall, and of Döderlein, who divides only the posterior cervical and uterine wall, should be abandoned, because they do not give us quite enough room. At the hands of experienced operators Dührssen's operation requires but seven to fifteen minutes, another advantage over the abdominal method, in which the closing of the uterus alone takes from fifteen to twenty minutes. Ill effects of the resulting scars are not to be feared, as five cases of Dührssen, Wennerström, Jerie, and von Bardeleben go to show. These cases were all observed in normal deliveries after a vaginal Cesarean section had been performed upon these patients during a previous pregnancy.

From the conservative to the radical vaginal Cesarean section is only a short step, the latter being indicated in those cases in which a carcinoma, a marked uterine infection, or an uncontrollable hæmorrhage is present. P. Müller's method of hemisection uteri with subsequent hysterectomy is then the best mode of procedure.

As regards the mortality, Dührssen collected 248 cases of conservative and radical Cæsarean section with a death rate of 1 per cent., after excluding all deaths due to causes other than the operation itself. On the other hand, Olshausen, who has obtained the best results with abdominal Cæsarean section abroad, reported a mortality of from 6 to 8 per cent. This marked difference in the death rate should cause all obstetricians to operate per vaginam rather than per abdomen. As a matter of fact if we follow the work and writings of obstetricians of note, we notice that they gradually changed their position from one of hesitancy to one of enthusiasm for the vaginal operation. I need only mention Bumm, Leopold, Zweifel, and von Winckel in Europe, and Fry and Williams in this country, all of whom have become staunch advocates of the operation, Fry even stating that since the introduction of the vaginal method, abdominal Cæsarean section has but few indications. I do not believe we are going too far in agreeing with Bumm when he says: "The value of the operation and the advance which its introduction into obstetrics represents, lie in the fact that we are placed into a position to open the uterus sufficiently to permit a delivery along the normal passages, without loss of time, in a clean cut surgical way, and at any moment during pregnancy or labor. No other method of dilating the unobliterated cervical canal at our disposal to-day is capable of accomplishing anything like a vaginal Cæsarean section."

We shall now discuss those operations which bring about an enlargement of the birth canal by cutting through some portion of the bony pelvis. In the beginning of the sixteenth century Severinus Pineus recommended such an operation, but not until 1777 was it performed on the living subject, when Jean René Sigault was the first to do so. The operations on the bony pelvis may be classified under two heads, symphysiotomy, in which a joint is divided, and hebostotomy (also called pubiotomy or hebotomy), in which one of the pubic bones is divided.

Symphysiotomy was at first enthusiastically received, only to be gradually abandoned on account of the variable results obtained by it. In Germany, Siebold, of Würzburg, was the first to perform one in 1778; he was followed by others, and in 1820 Ritgen was the last to recommend it for some time to come. Not until the last quarter of the past century was it again taken up, when, due to the improvements in technique and asepsis, the operation was again advocated by Morisani, Pinard, and Zweifel, but in spite of their agitation in its favor it did not gain a permanent place among obstetrical operations. It is chiefly indicated in contracted pelves, especially in flat and just minor pelves, but is contraindicated in the former when the true conjugate is under six and one half centimetres, and in the latter when it is under seven centimetres. Its disadvantages are so many that it can hardly be called an advance in operative obstetrics: the fact alone that a joint is opened and brought into connection with the septic aspects vagina from where it is only too frequently infected, is significant. The real dangers lie in the injuries necessarily inflicted upon the soft parts: the wound may enlarge during

the subsequent delivery or the urethra may be torn from its attachments, the bladder and corpus cavernosum clitoridis may be injured, injury of the latter being likely to be followed by a retropubic hæmatoma, which is often infected; deep vaginal tears are also frequently met with. Even when carried out subcutaneously, as recently advised by Zweifel, the complications become no less frequent, so that it is not surprising that most obstetricians, who have a large number of contracted pelves to deal with, have abandoned symphysiotomy in favor of a new operation devised to supplant it, namely, pubiotomy.

This new operation is not without faults, but offers many advantages over symphysiotomy. Though recommended in the seventeenth century, its present vogue is entirely due to Gigli, who advocated it in the latter part of the last century, when Bonardi and van der Velde were the first to perform it on the living subject. They were soon followed by Calderini, Morisani, Caruso, and others. The methods first suggested by Gigli and van der Velde were open ones; they exposed the os pubis and then divided it. More recently Döderlein devised a method, partly subcutaneous, and Bumm, Walcher, and Leopold introduced one entirely subcutaneous, the bone being divided either after a moderate or no dissection of the soft parts. In all the methods the vagina, urethra, bladder, and corpus cavernosum clitoridis lie outside of the field of operation; but Döderlein's has found the largest number of followers and has given the best results. He makes a small incision along the upper border of the pubes just internal to the tubercle and large enough to permit the introduction of the finger behind the bone, where the retropubic tissue and bladder are pushed away. Under guidance of the finger a carrier is passed behind the bone and brought out just external to the labium majus, where a small skin incision is made, then the carrier is threaded with a saw, withdrawn, and the bone divided. From the time that Döderlein introduced his partly subcutaneous method, pubiotomy has been more frequently performed, especially since Sellheim has demonstrated that the pelvic enlargement following pubiotomy is the same as after symphysiotomy. When we consider that in addition the results following pubiotomy have been more favorable than those of symphysiotomy, it is not surprising that the latter has been less frequently performed.

We may summarize the indications of pubiotomy by the statement that it is indicated in all cases in which perforation of the living child was hitherto resorted to, especially in cases of flat or generally contracted pelves in which there is a disproportion between the size of the fetal head and the size of the pelvis. From a practical point of view we may divide them into prophylactic and imperative indications. Under the first heading those cases of contracted pelvis are included, in which there was a previous stillbirth or difficult delivery; then hebotomy is best performed at the end of the first stage, and labor permitted to go on spontaneously. The second heading includes those cases in which mother or child is in immediate danger, or in which there has been an unsuccessful attempt at forceps extraction. Under the latter circumstance it is best

to perform the hebotomy with the forceps *in situ* and then to complete the labor instrumentally. Whenever possible one should get along without forceps, as the cases of hebotomy followed by spontaneous delivery have given the best results for mother and child. According to Baisch's analysis of 187 cases in which hebotomy was followed by forceps, the foetal mortality was 4.3 per cent., while in seventeen cases in which the labor was ended spontaneously all the children were born alive, the mortality being 0 per cent.

After symphysiotomy the average mortality among the mothers reaches 17 per cent., which Morisani, Pinard, and Zweifel, who performed the operation frequently, reduced to 8 per cent. Following hebotomy the mortality is only 4.2 per cent., which is reduced to 2.9 per cent. when those cases which were infected before operation are excluded. As regards the justly feared bladder injuries, I should like to mention that they occurred in 2.4 per cent. of the cases operated on according to Döderlein, and in 17.6 per cent. of the cases operated on according to Bumm. Cases of severe infections, bladder injuries, and one of fatal hemorrhage may surely be attributed to first trials, and will become less frequent as the technique improves. It cannot be denied that pubiotomy must be considered as competitive with abdominal Cæsarean section in certain cases.

As regards the after treatment, it is sufficient to dress the wound, and place a few adhesive straps around the pelvis, in addition to supporting it on either side with sand bags. The healing in normal cases goes on quite rapidly, so that the patients can get up out of bed at the end of the third week, without any disturbances as to function.

It would be going too far were I to discuss such operations as the removal of large tumors during pregnancy and labor, the resection of pelvic veins and hysterectomy for septic conditions during the puerperium; nevertheless, they are good examples of the modern operative tendencies in obstetrics.

Before closing I wish to touch upon the question as to which of the operations which I mentioned can and should be performed by the general practitioner, who so frequently meets with difficult obstetrical cases. I have already mentioned that the vaginal Cæsarean section, according to Dührssen, gives good results in the hands of the general practitioner who has had some surgical training. It is different with respect to pubiotomy, the result of which in a given case cannot be foretold and concerning which many questions still remain unsettled. I consider it a risky undertaking for the general practitioner, and believe the operation should be confined to the specialist, a man familiar with pelvimetry, obstetrical diagnosis, and the technique of the operation—above all, one equal to the task of meeting any of the complications liable to come up during and after the operation. Final judgment has not been passed on pubiotomy, but up to the present time most obstetricians abroad look upon it with favor. A definite opinion cannot be formed until the histories of more cases have been published, and for this reason I hope the operation will find more extensive trial in this country in the future.

From what has been said we cannot fail to draw the conclusion that a "new obstetrics" has developed in the last two decades, due chiefly to the adoption of modern surgical principles, and that obstetrics no longer fails to keep pace with the advances in other branches of medicine.

36 WEST FIFTY-NINTH STREET.

#### GALLSTONE DISEASE AND ITS SURGICAL ASPECT.\*

BY FORBES HAWKES, M. D.,

New York,

Attending Surgeon, Trinity Hospital; Assistant Surgeon, Presbyterian Hospital; Consulting Surgeon, Nassau and St. Joseph's Hospital, L. I.; Instructor in Surgery, Columbia University.

When a positive diagnosis of gallstone disease has been made in a given case, does this condition belong among those to be treated by medical means or by surgical ones?

If we exclude those cases where gallstones are being constantly passed with slight discomfort to the patient (I am not at all sure that even these should

\*Paper read before the Medical Association of the Greater City of New York, on November 18, 1907.

be excluded) and those cases where the risk of any surgical procedure is very great (e. g., from cardiac, pulmonary, renal or arterial changes, or from marked overadiposity) I think that I am voicing the present day opinions of the greater number of conservative surgeons when I say that the remaining conditions may best be treated by surgical methods, and the earlier the better.

Early gallstone surgery has been and is still being opposed by many medical men in much the same way that early surgery of the appendix was opposed. Not long ago an article appeared written by a medical practitioner of much experience in this city discussing the subject of operation in gallstone disease. He said that many cases had best be treated medically, boasting that he had carried one patient through somewhere between ten and twenty severe attacks of gallstone colic.

That this patient was running a great risk in any one of these attacks, and in the interval as well, I think we would all admit.

If we exclude those conditions previously mentioned gallstones should be removed (and the ducts drained in many cases), not necessarily just as soon as the diagnosis is made, but shortly thereafter for the following reasons: Patients with gallstones are liable at any time to one or more of the following serious complications: (a) Abscess of the gallbladder; often with (b) subphrenic abscess secondary to it; (c) gangrene of the gallbladder; with ensuing (d) spreading peritonitis; (e) perforation of the gallbladder into the duodenum, stomach, or transverse colon; with occasional (f) intestinal obstruction from the contents or from subsequent constriction bands; (g) impaction of one or more of the calculi in the common or hepatic duct, followed by obstructive jaundice; later by acute ascending infection along the liver ducts; and resulting in (h) abscess of the liver localized and operable, perhaps, or diffuse and beyond the reach of the surgeon; (i) chronic hepatitis; and (j) chronic pancreatitis; (k) cancer developing in the vicinity of the gallstones; and finally (l) changes in the kidneys (chronic nephritis).

Before surgeons could conscientiously recommend operation as a routine measure to patients with gallstones, they had to show that the operation *per se* was not an extrahazardous one, and that their final results were better in the cases operated on than in those treated by medical means alone. This has now been done by many surgeons the world over. Gallstones are being recognized more and more as objects which the surgeon is called upon to remove, and the disease which has produced them as one to be treated at the same time by surgical drainage. No one would venture to-day to question the propriety of operating early in appendicitis, because some patients who have been allowed to run on to diffuse peritonitis from appendix infection have died following too late an operation. In the same way in the gallstone case should it be. Patients should be operated upon early, not late.

The most valuable type of surgery is that which aims to remove the source of the trouble, in this case both gallstones and infection of the ducts, before dangerous complications arise or permanent harm has been done. In this way the time that the patient is kept in bed is shortened, the strongest possible

scar is obtained, and the digestive disturbances soon disappear.

There are two things that have delayed the recognition of gallstone surgery in its proper value: 1, The attacks of gallstone colic do not at the start seem to be as dangerous as attacks of appendicitis often are; and, 2, owing to the situation of the gallbladder and ducts the diagnosis is often not made until several attacks have occurred. Marked jaundice, we know, is infrequent in cases where the stones and the infection are located mostly in the gallbladder or cystic duct. Attention is therefore often diverted to the stomach as the primary seat of the trouble, and the patient is treated for indigestion for years, while gallstones are accumulating and secondary changes are occurring in the bile tracts, liver, stomach, pancreas, intestines, and kidneys.

I have heard surgeons criticised because in some of their operative cases they were not able to remove all of the calculi at the time of operation. Many calculi are undoubtedly formed at a late period of the disease in the ramifications, which often are inaccessible, of the hepatic ducts in the liver. They are due to the constantly ascending infection of a mild grade. The best way to have prevented such formation high up would have been to have removed the preceding gallstones below and to have drained the ducts at an earlier date. Of course patients may refuse operation in this early period, not realizing the serious nature of their trouble, but the medical practitioner advising operation at this time will have given his patient the best advice, and the responsibility for subsequent stone formation and further duct infection cannot then be laid at his door.

The well known fact that gallstones are often found at autopsy in patients dying from other causes, and that they have apparently been the source of little or no discomfort is often mentioned, when surgical treatment is discussed. This fact has but little bearing on the question, for those that give rise to no symptoms are not brought to the attention of medical or surgical practitioner. We are here considering the cases that present symptoms. What do medical practitioners say that they can do in the cases that are not operated on in the way of arresting the formation of gallstones or of dissolving them or of helping them through the ducts safely?

As to the prevention of their formation, it is believed by some that by keeping the bowels thoroughly cleared out by saline laxatives—by diluting the bile by large draughts of water—by giving certain drugs and adhering to a certain diet, further infection can be arrested. Much good can undoubtedly be achieved by these means, and we see the symptoms often quieted down for a time in this way. That the stones are not forming during this time, however, higher and higher in the ducts, we cannot say positively. As to the dissolution of stones already formed no proof has ever been adduced that such an occurrence can be brought about in the living body. As to helping the stones down the ducts some practitioners feel that the administration of olive oil over long continued periods has been of benefit service in this way. While I have seen this form of treatment followed by cessation of pain in a certain number of cases I cannot conscientiously say that stones have passed in greater quantities or

with less pain than under other methods of treatment. Many stones are too large to pass through any of the ducts. Such are apt to cause ulceration. The small faecal masses passed during the olive oil treatment have often been mistaken for gallstones. I am not now dealing with the subject of the surgery of the gallbladder, and I shall not here take up the question whether the gallbladder should usually be removed or not, but my experience justifies me in the opinion that if we are led to exclude the cases mentioned in the first part of this article the proper treatment for the others is to remove the gallstones when they are distinctly diagnosed, and at the same time to drain the ducts of their infection, so that subsequent serious trouble may be avoided. It is not believed, after the stones have all come away from the gallbladder and from the drained ducts, that there is any subsequent stone formation, except in very rare cases. Stones found later are usually believed to have been either overlooked or inaccessible.

The conclusions which follow are based on my own operative records of patients suffering from gallstone disease. In all of them gallstones were found in numbers varying from one to 2,059. In the first division are thirteen cases operated on for gallstones before serious complication had set in. These are the cases of so called indigestion, dyspepsia, gastritis, biliousness, etc., etc.; no deaths, no failure of cure. In the second division, nineteen cases operated on after the development of serious complications, ten patients cured, three improved, six deaths. The causes of death in these six cases were as follows: Septic foci scattered through the liver (septic cholangitis from calculi), one case; carcinoma of bile ducts and of the liver following old standing gallstone disease, two cases; septic peritonitis with septic nephritis following acute infection of a stone bearing gallbladder, one case; gangrene of gallbladder with subphrenic abscess, and perforation into transverse colon, general peritonitis, double septic pneumonia, one case; calculus imparted in ampulla, with chronic pancreatitis and chronic cholecystitis, matting parts together in one cartilaginous mass, with fatty degeneration of the liver and chronic nephritis, death due later to uræmia, one case.

**Conclusions.**—Provided the patient is a good surgical risk:

1. Gallstones should be removed at an early date from gallbladder or ducts; such infection is treated by drainage of the ducts. At this time the operation is comparatively safe, convalescence is prompt, and cure lasting.

2. Serious complications are liable to arise at any time in patients with chronic gallstone disease. Long journeys, in which efficient surgical aid cannot be secured promptly, are distinctly hazardous. Operations at this time are much more serious, they are often necessarily incomplete, and the outlook for permanent cure is less bright.

3. Cancer is liable to develop at any time at or near the seat of irritation. Operation then is very hazardous and the outlook bad.

4. Medical practitioners should familiarize themselves with the results obtained by the surgeons today in the early uncomplicated cases.

## DIAGNOSIS AND TREATMENT OF BENIGN TUMORS OF THE RECTUM.\*

By H. A. BRAV, M. D.,  
Philadelphia,

Proctologist to the American Hospital for Diseases of the Stomach.

In selecting the theme of my paper I was actuated by a desire to present a subject, a discussion of which would not only be of considerable interest but also of practical value to every medical practitioner. Since benign tumors of the rectum are rarely diagnosed by the general practitioner, and often overlooked by the general surgeon, it will, I thought, be of interest to all of us to review this subject briefly.

Benign tumors of the rectum comprise growths which, as a rule, have a pedunculated attachment and a pendulous extremity. These growths are quite often met with in either sex and at any age, but are more common in women and children. They vary in size, shape and form, and may be single or multiple, and are usually attached by a single stem, but they may have two or more attachments. These neoplasms are also known as polyps on account of the fact that they are attached to the rectal wall by a pedicle or stalk. The pedicle consists of a fold of mucous membrane containing blood vessels which supply the growth.

The polypoid tumors found in the rectum are as follows: (1) The adenoma or glandular polypus, (2) the fibroma or fibrous polypus, (3) the villous tumor or villous polypus, (4) the myxoma or myxomatous polypus.

1. Of all these varieties the adenoma is the one most frequently met with. This tumor is very common in childhood, but extremely rare in adult life. They are soft when composed of the constituents of the mucous membrane, while those which are composed of both, the elements of the mucous membrane and submucous connective tissue, are generally hard and are spoken of clinically as a fibroadenoma. Adenomatous polyps are usually single, but sometimes two, or even more, may be encountered within the same patient. They are generally the size of a large cherry, they may, however, be a little larger. These growths have the color of the mucous membrane of the rectum, but when they protrude at the anus they have a purple red appearance. They are generally found attached to the posterior wall of the rectum and at a point within reach of the finger, but they may arise from any other part of the rectum and be attached so high up that the finger alone will not reach it. When the pedicle is long and not attached high up in the rectum the polyp will protrude during the act of defæcation and appear at the anus as a dark red roundish tumor with a bleeding surface. It usually returns spontaneously into the rectum immediately after defæcation, but sometimes it is necessary for the patient to replace it above the sphincters after each stool. A small adenoma may exist for a long time without giving rise to symptoms of its presence. A rule, however, hæmorrhage occurs from the abraded surface of the growth produced by the passage of hard scybalous masses over it, it also gives rise to a straining sensation when caught by the sphincters.

Read before the Northern Medical Association, June 1905.

The diagnosis is, comparatively speaking, easy. The passage of blood from the rectum in a child, usually under ten years of age, with or without pain on defecation, with or without straining, generally means the presence of polypus. A digital examination should now be made in order to locate the growth. The best way to accomplish this is to sweep the finger around the whole circumference of the anal canal as far as it can be reached when the growth can be felt or drawn down and sometimes brought out through the anus. Growths attached higher up in the rectum can only be located under an anæsthetic. Owing to the fact that polyps sometimes protrude at stool they are frequently mistaken for hæmorrhoids and treated for that condition. I have a record of several such cases, which have been treated for piles by the application of astringent and sedative ointments.

The treatment of polypi consists in their extirpation under the influence of an anæsthetic. The sphincters should be dilated and the growth pulled down with thumb forceps, ligated and cut off as close as possible to its point of attachment to the rectal wall. Some surgeons apply a clamp to the pedicle, sever it, and cauterize with the Paquelin cautery.

When the pedicle is long and slender and located in the upper rectum the polypus may be twisted off by simple torsion. The after treatment consists in confining the bowels for four days whence they are opened by the administration of fractional doses of calomel followed by a saline. After the removal of an adenomatous polyp in an adult having passed middle life it is necessary to examine the patient from time to time, because carcinomatous degeneration has been found to follow some cases. Spontaneous cure of polyps sometimes takes place. The reason for this is that the thin pedicle is torn through by the passage of hard feces and the growth passes out with it. Strangulation of the tumor by the sphincter muscle will occasionally cause them to slough off.

2. The next most common benign tumor found in the rectum is the fibroma, or fibrous polypus. This growth consists of fibrous tissue and has a short, tough pedicle. It is usually situated within the first two inches of the rectum and varies in size from that of a hazelnut to a walnut. These growths are mostly found in adults and are usually multiple in character. They may protrude during defecation and be mistaken for internal piles, especially when both conditions co-exist in the same case. A fibroma can readily be diagnosed by a digital examination when the finger will detect a firm, hard growth which can sometimes be drawn down the anal orifice and examined. A small fibrous polypus may exist for some time without any untoward effect, it will, however, soon bring on spasms of the sphincter and levator ani muscles which ultimately become hypertrophied, and indurated. When the pedicle of a fibromata happens to be partially torn by the passage of a hard fecal mass, the patient experiences a burning pain and a slight loss of blood. The pain, which sometimes lasts for hours after stool, is suggestive of an anal fissure. Examination, however, will soon disclose the presence of a fibrous polypus.

The treatment consists in the removal of the growth by applying a ligature to its base and cutting off the growth, or by the application of a clamp cutting it off, and cauterization of the stump.

3. One of the rarest of all the benign tumors found in the rectum is the villous tumor. This neoplasm may reach the size of an orange and has a handlike, short, fleshy pedicle. Its surface is generally lobulated, giving it a cauliflower appearance. A villous polypus is found only in adults or in old persons, who, as a rule, complain of diarrhoea on account of the watery discharge from the bowel, which makes them go to stool frequently. These patients also complain of a dull, aching pain in the rectum radiating to the sacrum. They bleed occasionally, but the hæmorrhage generally originates not from the surface of the tumor but from the co-existing piles. Patients suffering from villous growths generally lose flesh and strength and have a cachectic appearance. When completely removed this tumor seldom recurs, it may, however, become cancerous and return after extirpation. I have a case on hand now which confirms this statement:

Mrs. E. L., aged forty-five years, had a typical villous growth in the rectum which I completely removed a year ago. Seven months after the operation the patient came back to me complaining of a bearing down sensation in the rectum, straining, mucopurulent and bloody discharge at stool. She was anæmic, emaciated, and extremely nervous. A digital examination revealed a narrowing of the anal canal due to a carcinomatous infiltration of the rectum extending up the bowel for about six inches. Slight involvement of the bladder and lymphatic glands were noticeable. The patient refused another operation whence I had to resort to palliative measures. The stricture, however, grew so rapidly that a passage by the rectum was impossible and she consented to have a left inguinal colostomy performed. This operation will probably prolong her life by relieving her temporarily of distressing symptoms of obstruction.

It is evident that an early diagnosis is imperative in the cure of these cases. The only procedure necessary to establish a correct diagnosis is a digital exploration of the rectum. Careful manipulation of the finger will detect a growth attached to some part of the bowel by a broad pedicle. In the majority of cases, however, this tumor will be found attached to the posterior wall of the rectum. The growth rarely protrudes from the anus, and still more rarely do we find more than one growth in the same case. The treatment of a villous tumor consists in an early removal of it by operation. Under the influence of an anæsthetic the sphincters are dilated and the growth brought down through the anal orifice. A clamp is then applied on the pedicle which is transfixed and ligatured in one or more places near its origin from the rectal wall and is then divided. If there is no distinct pedicle the growth must be extirpated by resecting the portion of the bowel to which it is attached, and the resulting wound brought together by sutures.

The after treatment consists in rest in bed and keeping the bowels confined for a few days. On the fifth day the bowels are made to act by the administration of a cathartic. On account of the occasional recurrence of this tumor at the site of the scar of the previous operation it is advisable to ask the patient to call for a rectal examination every three months after the operation has been performed.

4. The myxoma or myxomatous polypus consists of pure mucous tissue. This growth is very rarely

encountered with, and there is only one case reported by Gant.

There are other forms of rectal neoplasms, namely, the myoma and lipoma. These, however, are so rarely met with that they are considered pathological curiosities. A description of these would be of no practical value.

926 NORTH FRANKLIN STREET.

#### COLORIMETRIC ANALYSIS OF THE SALIVA, WITH THE CLINICAL SIGNIFICANCE.

By BERNARD R. LE ROY, M. D.,  
Athens, Ohio.

The study of the saliva from a pathological standpoint has been neglected and has not received the attention it deserves, but from the studies of the few eminent observers who have given it much thought, much, very much indeed, may be gathered that is of interest to the clinician, and if made use of in diagnostics and therapeutics will result in rapid advancement in the eyes of the profession, as well as in the thoughts of the laity, for when applied intelligently the results more than repay the trouble taken in the examination.

That all practitioners are not in a position to carry out the necessary laboratory studies is conceded, yet from the instructions given below any one can be able, after a few trials, to carry out the laboratory work with ease.

The resulting exactness of the examination will indicate to the physician the lead or direction in which he must look and prescribe for the existing wrong or diseased condition. This will enable him to prescribe with more exactness and with less of the "shotgun hit or miss" method, and when once started the fascinating attraction of the work makes it intensely interesting and adds zest to one's study of disease.

As stated, the literature on the subject is meagre, and with the exception of Fenwick, Kyle, Kirk, and a few writers, who only incidentally touch upon the subject, nothing in the nature of an exact investigation of the saliva pathologically has been done.

The method of examination is colorimetric and qualitative in character, and the reagents are to be used in the smallest quantities compatible with color reaction, the commonest error being the use of too large a quantity of the test solutions.

All test solutions are to be made of 5 per cent. strength, unless otherwise stated, and are to be made up with distilled water; other materials needed are litmus paper and the finest quality of filter paper, a porcelain tablet with twelve discs, and several small test tubes.

After securing the saliva note the color, odor, whether viscid or fluid, note the nature of the sediment, reaction, and make note of the quantity secreted daily.

Place a good sized drop of saliva in each of the discs of the porcelain tablet, and should the operator be in normal health he should examine his own saliva at the same time by placing it in the discs at the bottom of the plate and testing each in turn. This will be good practice and will enable him to compare diseased saliva with the normal.

**Sulphocyanides.**—In the first disc in which you have placed a large drop of saliva add one small drop of a slightly acidified solution of ferric chloride; if the sulphocyanides are present in normal quantities there will be a faint pink coloration or aura, which will spread throughout the saliva, starting from the dark brick red where the reagent is still unmixed with the saliva. This faint yet decided pink coloration stands for normality in the sulphocyanides and will not be seen in cases where they are absent; in cases where they are increased the color will be deepened into all shades up to a nearly dark blood red, which is very intense and quickly prevails throughout the saliva being tested, representing the varying amounts of the sulphocyanides that may be present. Or, to the saliva add one drop of solution of cupric sulphate, then add one drop of a freshly prepared tincture of guaiac, when a blue color will indicate the presence of the sulphocyanides, but upon the other hand, should the color be green, then it is due to ammonia; in case the color is green with a few streaks of a dark blue through it, then it indicates that the sulphocyanides are present in small quantities with an increased content of ammonia.

**Ammonia.**—In the centre of the next drop place a tiny drop of Nessler's reagent, when, if ammonia is present, a reddish yellow color and precipitate will result, while around throughout the saliva will be noticed a faint pinkish color or aura encircling the reagent. The color will depend upon the amount of ammonia present and will be shaded accordingly.

**Chlorides.**—Add a small drop of a solution of potassium chromate in centre of saliva, then add a very minute drop of a solution of silver nitrate, and should the chlorides be present the reddish silver chromate, being soluble, will dissolve in proportion to the amount of chlorides present; add another drop of silver nitrate and so on until no more is dissolved, and thus estimate the amount of chlorides present.

**Oxalic acid.**—Add a drop of full strength acetic acid, then one drop of a solution of calcium chloride; a precipitate of oxalate of lime takes place if oxalic acid is present, and the precipitate should be carefully examined under a high power microscope for the crystals of the oxalate of lime.

**Urea.**—Take several c.c. of saliva and evaporate slowly over water bath to one fifth or less, add alcohol, shake well, filter, and evaporate to dryness, dissolve residue in distilled water and treat with nitric acid, set aside to cool, when nitrate of urea will separate after a time in characteristic rhombic or hexagonal plates.

**Formaldehyde.**—Add a drop of Nessler's reagent and a reddish yellow, then black coloration takes place rapidly with a blackish precipitate at the end of reaction; this is not, as some writers have stated, one of "yellow precipitation," but is very distinct from the reaction received with ammonia, and is given here for two reasons, the one just given and because of the common use of formaldehyde.

**Acetone.**—Add one drop of an alkaline solution of sodium nitroprusside so dilute as to have only a slight red color; should acetone be present a ruby red color is produced, which changes to yellow; add acid and boil, when a greenish blue or violet color will result. Or add a drop of solution of iodo-

potassium iodide; then add a drop of caustic potash (U. S. P.), let stand; if no more than a trace of acetone is present iodoform will be precipitated.

**Sodium.**—To find the base salt of the saliva, the saliva is placed in a small test tube and a drop of a solution of potassium pyroantimonate is added; if sodium is present a faint or slight crystalline precipitate will take place.

**Potassium.**—Place saliva in a test tube and add an equal amount of alcohol; this prevents the sodium present from taking part in the reaction, and add one drop of a solution of hydrochloroplatinic acid when a slight precipitate indicates potassium.

**Calcium.**—Place a quantity of saliva in a test tube and add twice the quantity of distilled water, shake well and add a quantity of solution of ammonium oxalate (U. S. P.), when if calcium is present a white precipitate falls which is insoluble in acetic acid, but is soluble in hydrochloric or nitric acid.

**Silicates.**—No known method of producing color reaction is known to the writer; the qualitative method, being rather difficult, will not be given here.

**Nitrites.**—Take and mix the following: Phenol, one part; sulphuric acid, four parts; water, two parts; and add small quantity of a potassium hydroxide solution. Place a small quantity of this in a small test tube, then add an equal quantity of saliva, being careful to not mix them, the saliva being the upper layer; let stand for several minutes, and if nitrites are present a deep red colored band will be present at the line of union of saliva and reagent, depth of color depending upon the amount of nitrites present; or the following may be used: Place a quantity of saliva in a small test tube, add a few drops of Ilasvay's reagent, and gently heat, when if nitrites are present a red color will develop.

**Lactic acid.**—To a test tube of water add a few drops of a solution of iron sesquichloride; shake, pour half into another tube, and use this as a control; to the first tube add a number of drops of saliva, when in the presence of lactic acid the test solution will turn a distinct yellow color, which appears marked when compared with the control tube. This test is delicate. (Simon's modification of Kelling's.)

**Opium.**—The same test is used in opium eaters' saliva as in the sulphocyanides, producing the same reaction; now add a drop of a solution of corrosive sublimate, and if iron meconate is present the color remains unchanged, but will disappear if due to the sulphocyanides.

**Morphine.** Add one drop of a neutral solution of ferric alum to the saliva of morphine eaters, and you will get a dirty green color, which is intensified by heating the tablet and adding one drop more of the reagent. Or you may substitute for the alum a neutral solution of ferric chloride, producing the same results, but more delicate in action.

These tests are very clever in detecting patients addicted to the habit of eating these drugs.

**The rosolic acid test paper for testing for acids or alkalis.**—Soak strips of extra fine grade of filter paper in an alcoholic solution of rosolic acid of such strength as to color the paper a delicate salmon pink when dry. Now place a drop of saliva on the paper, and if acid the paper will not be affected, unless the saliva is greatly acid, when it will turn an orange yellow; but if the saliva is alkaline the paper

will turn or change from a faint pink to a bright brilliant red, according to the degree of alkalinity present, making a beautiful contrast to the delicate salmon pink of the test paper.

**Proteids.**—Saliva from the submaxillary gland contains proteids, a nucleoproteid; place a quantity of saliva in a small test tube and add a few drops of a solution of cupric sulphate, mix, and note the color; if it has turned towards a blue color it indicates the presence of ammonia, but if it is a pale green then add a few drops of ammonia, when in the presence of nucleoproteids it will turn a deep blue.

The solids of the saliva are the phosphate and carbonate of lime and silica; all are concerned in the formation of tartar and sordes, and always in an alkaline saliva. The lime salts have been studied, but whence comes the silica? From studies along this line the writer is of the opinion that silica is of fundamental use in the life history of the living cell, always found in extremely small quantities and therefore overlooked in the summing up.

**Clinical significance.**—Fenwick states that the sulphocyanides bear a relationship to the amount of sulphur in the bile, and that when the bile is diverted from the alimentary canal the sulphocyanides disappear from the saliva.

The sulphocyanides and ammonia in normal saliva are in about equal proportions and in very small amounts.

When the sulphocyanides disappear from the saliva we have a condition that needs our careful attention, and if ammonia is increased in quantity we have a grave condition, indeed, to combat; this is an hypoacid condition and accompanies all the graver forms of disease; for instance, this is the state of affairs in all diseases of the nervous system, i. e., absence of the sulphocyanides with ammonia present in large quantities, the larger the amounts of the latter the more grave the condition. This is true of epilepsy, paralysis, dementia præcox, and all forms of nervous diseases resulting from lues. And when I have been able to detect the sulphocyanides in these cases I always felt sure of a period of improved state of health, and upon the disappearance of the sulphocyanides from the saliva I was just as certain that the old attacks would return. We also have this state of affairs in all forms of fevers, exemplified in its extreme in the typhoid state. Here, too, we will notice the appearance of the sulphocyanides in the saliva in advance of returning health; indeed, this holds good in all cases of recovery from any and all forms of disease.

Upon the other hand, when we have an excess of the sulphocyanides in the saliva, giving a deep dark blood red reaction, and it continues so for a space of time, I look for a lesion in the brain, heart, or in the kidney, and I pay special attention to these organs.

When we have a hypoacid condition the patient cannot tolerate acids nor iron—that is, these remedies will not agree with the patient; but change the ammonia base to potassium and the patient will ask for acid drinks! Sodium base will cause the same changes to take place in the smaller forms of acidity.

When the saliva is exceedingly acid exciting the mouth for microorganisms which may produce car-

tic acid, then examine the saliva for oxalic acid; in these cases the saliva upon standing turns a dark yellowish brown, and the enzyme ptyalin will always be absent, no doubt having some connection with the stomach troubles which accompany this state of affairs. With lactic and oxalic acid present in small quantities we have caries of the teeth.

When urea is present or combined with the sodium phosphate to form the acid sodium phosphate we have a very irritated condition of the mucous membrane of the throat and mouth, causing the parts to become sensitive, the secretions to become acrid and burning in character, producing rhinitis and catarrhs. (Kyle.)

When ammonia is in excess there is a diminished amount of both oxygen and carbonic acid in the saliva, with a rapid tendency to decompose; this state of affairs is present in all states of sepsis, and with acetone present we have a condition of auto-infection of the system, with indican in the urine.

In all cases of exhaustive discharges from the body we find the sulphocyanides absent from the saliva, and in case of recovery their reappearance again heralding a return of health or a period of improvement.

When we have sulphureted hydrogen, noticed in the breath, or the patient complains of a rotten egg taste, the sulphocyanides are absent from the saliva, and when the proper attention is given the stomach the sulphocyanides reappear in the saliva, and the sulphureted odor and taste disappear. In all these cases where we have the so called rotten egg taste I have found that it is not altogether due to sulphureted hydrogen, but is in a great measure due to nitrogen, and that upon carefully analyzing the odor I have found that it more closely resembles the odor of burnt feathers than sulphureted hydrogen, the stench causing one to take snap judgment.

In cases where the reaction for the sulphocyanides gives a dark brown color instead of the brick red to a dark blood red color, and this reaction is obtained time and again in the same case, you may notify the friends of a fatal issue unless you can produce a decided change, and that within a short space of time.

Fenwick states that in old people where he perceived the reaction indicating an excess of the sulphocyanides with a steady persistence that the case would develop fatal symptoms.

In heart disease, for instance mitral disease with dilatation, wherein there is developed a back pressure and the sulphocyanides are absent, the case will terminate fatally; but if they are present and increase in amount the patient will improve or recover.

In rheumatism, if the sulphocyanides are present and an increase is noticed, recovery will be rapid; but if present in excessive amounts then recovery will be protracted.

In most of the chronic skin diseases the sulphocyanides are found in excessive amounts.

When we have the smell of hydrogen sulphide in the breath and ammonia in the saliva, with absence of the sulphocyanides, we can with a certain degree of positiveness diagnose dilation of the stomach with albuminous putrefaction in the small intestines; also that it is from benign causes and that this condition is never present with carcinoma of the stomach, nor is it present when lactic acid is found in content of the stomach.

There is in nephritis an increased amount of urea in the saliva.

As I have stated before, the color indicating the normal amount of the sulphocyanides in the saliva is a faint yet decided pink color; this fact I have arrived at from several thousand examinations and cannot agree with Fenwick when he states that the normal color is one of a medium dark blood red. This last color I found to be normal with children and young people undergoing a somewhat rapid growth, but not an average for all cases of normal health irrespective of age.

When the patient complains of a soapy or sappy taste, look for ammonia in greater or less quantities in the saliva; when of a salty taste, look for sodium as the predominating base; when of an acid taste, look for lactic or oxalic acid, should the disease be in the neck or head; but if the disease is in the body or limbs, look for urea with a sodium base; if taste is of a putrid, horrible nature, look for ammonia with one or more of the other abnormal contents found in the saliva.

In looking over the record of several thousand examinations, several prominent points stand out in bold relief: First, that the sulphocyanides, as first noticed by Fenwick, vary in amount in different diseases and in different stages of the same disease.

That an excess of the sulphocyanides, or an excess of urea with a sodium base, will produce an exceedingly irritative condition of the mucous membranes of the throat, nose, and mouth, as mentioned by Kyle.

That in all cases of disease the constant presence of ammonia in greater or smaller amounts, far above the normal content, is always to be found; the greater the amount, the more serious the condition of the patient.

That in all diseases of the nervous system the content of ammonia is in excessive amounts; and in epilepsy it is greater just before, during, and immediately after the attacks; in cases where the spells come at some interval the sulphocyanides will reappear in the saliva during the free period, to disappear before the next attack, to be replaced by ammonia in excess.

That in convalescence the base salt of the saliva should be one of potassium.

That nitrogen, and not altogether sulphureted hydrogen, is the gas that arises from benign diseases of the stomach and intestinal fermentation, and that these gases are not present in malignant forms of diseases of these organs.

As the saliva contains more oxygen than does the blood plasma, and a very large amount of carbon dioxide, it would be interesting to learn the reason of this and to know why this is the normal condition. Whence comes the normal as well as the abnormal content of the saliva?

In conclusion, permit me to speak of morphine and opium in this method of diagnosing: Morphine, no matter how administered, may be detected in the saliva within three minutes! Opium, no matter how given, may be detected in the saliva from within a few minutes to several hours, and in opium eaters it may be found in the saliva days after taking the last dose. Chloral may be found in the saliva as chloral or as formates, and thus be detected.

## Our Readers' Discussions.

### A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows:

LXXI.—How do you treat gallstone colic? (Closed February 15, 1908.)

LXXII.—How do you treat fracture of the patella? (Answers due not later than March 16, 1908.)

LXXIII.—How do you treat seasickness? (Answers due not later than April 15, 1908.)

Whoever answers one of these questions in the manner most satisfactory to the editors and their advisors will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred words.

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. All papers contributed become the property of the JOURNAL.

The prize of \$25 for the best essay submitted in answer to question LXX has been awarded to Dr. Beverley R. Tucker, of Richmond, Va., whose article appeared on page 493.

### PRIZE QUESTION NO. LXX.

(Continued from page 407.)

Dr. Joseph J. Rowan, of Philadelphia, writes:

Alcoholism, according to Dr. Tyson, is "the effect on the human economy of the intemperate use of alcohol in some one of the forms in which it is used as a beverage."

Ordinarily, garrulosity, flushing of the face, and an excited mien precede the incoherent speech, staggering gait, and final stupor. If seen in any stage prior to the stupor, the diagnosis is apparent, but when seen for the first time after the stupor supervenes a distinctive diagnosis must be made between the following conditions: (a) Alcoholic stupor, (b) apoplexy without fracture of the skull, (c) apoplexy with fracture of the skull, (d) opium poisoning, (e) uræmic coma, (f) unconsciousness preceding acute mania, and (g) unconsciousness in Menière's disease.

(a) In ordinary drunkenness the patient lies in a heavy sleep, from which he can be aroused by shaking or pinching. He may mumble a few incoherent words, but immediately falls back again into the same heavy sleep. On examining the pupils of the eyes they will usually be found dilated, and the odor of alcohol can be detected on the breath.

(b) and (c) In apoplexy without fracture of the skull the patient lies in a heavy sleep, from which he can be aroused by shaking or pinching. He may mumble a few incoherent words, but immediately falls back again into the same heavy sleep. On examining the pupils of the eyes they will usually be found dilated, and the odor of alcohol can be detected on the breath. (b) and (c) In apoplexy without fracture of the skull the patient lies in a heavy sleep, from which he can be aroused by shaking or pinching. He may mumble a few incoherent words, but immediately falls back again into the same heavy sleep. On examining the pupils of the eyes they will usually be found dilated, and the odor of alcohol can be detected on the breath.

ing thud, while the sound side fell with more resistance and more easily.

(d) Uræmic coma may also be confounded with alcoholic stupor. In this condition the odor of alcohol on the breath is missing, while that of urine may be present. In the absence of symptoms above mentioned as characteristic of these states, the catheter must be passed, and the urine thus obtained examined for the presence of albumin and casts. If found in any quantity, and the symptoms of other conditions lacking, the diagnosis of uræmic coma is justifiable. The pupils, in uræmia, give us no material aid, for they are variable, being sometimes dilated and sometimes contracted.

(e) In opium poisoning the pupils are invariably equally contracted, even to the size of a pin point, and the face is commonly pale. A pin point pupil always indicates the presence of opium.

(f) The condition of stupor which sometimes precedes acute mania I mention because while a resident physician at St. Mary's I was confronted with a case of this kind. The pupils were equal, neither dilated nor contracted, the urine contained no albumin or sugar, there was no paralysis, and the patient could not be aroused. The breathing was not stertorous, nor was the breath alcoholic.

(g) Menière's disease, or labyrinthine vertigo, must also be considered. The vertigo, staggering gait, nausea, and even unconsciousness being sufficiently similar to alcoholism to demand consideration in arriving at a diagnosis.

A final word as to the presence of alcohol on the breath. Too much reliance must not be placed upon its presence. The laity are prone to pour alcohol in some form or other down the throat of every person suddenly taken ill, and a person stricken with an apoplectic stroke or otherwise made unconscious is very likely to be dosed with alcohol before the arrival of a physician.

Dr. J. J. O'Sullivan, of Pittsburgh, Pa., states:

The conditions which may stimulate and with which alcoholic stupor is apt to be confounded are:

Opium poisoning, strychnine poisoning, belladonna poisoning, chronic plumbism, sunstroke, the coma of pernicious malarial fever, cerebrospinal fever, pneumonia, cerebral compression, diabetic coma, uræmic coma, epileptic coma, apoplectic coma, disseminated sclerosis, paralysis agitans, tabes dorsalis, parietic dementia, and hysteria.

In many of these conditions it is almost impossible at first to diagnose them from alcoholism on account of the close similarity in symptomatology, and a history of the case if obtainable may materially aid us in arriving at a diagnosis.

Very often the alcoholic condition is concurrent with some other distinct pathological process. An individual may be intoxicated and have either pneumonia, sunstroke, cerebral compression, diabetes, or serious renal trouble. Acute or chronic alcoholism may be the exciting cause of rupture of a cerebral bloodvessel. The strain on diseased renal organs incident to an *Arabis diabanthensis* food in the condition of uræmia. Thus it will be seen that alcoholism may be the exciting cause of a number of diseased conditions, from which it may be difficult or impossible to distinguish it.

It is assumed in this article that the alcoholic condition is independent of any other pathological state

which may exist coincidentally in the same individual. The distinctive diagnostic features only are considered. For convenience of description and the sake of brevity, the distinctive diagnosis in each case is outlined in tabulated form.

#### *Alcoholic Stupor.*

1. Skin cool and clammy.
2. Respirations normal or slightly accelerated.
3. Pulse rapid and feeble.
4. Pupils dilated or equally contracted.
5. Stupor may be supplemented by intervals of wakefulness and is not so pronounced as in opium poisoning.
6. Presence of von Wedekind's sign, viz., strong pressure on the supraorbital notches may bring an alcoholic to his senses.

#### *Alcoholic Stupor.*

1. Muscles are relaxed.
2. There are no convulsive movements.

3. Respirations normal or slightly accelerated.

4. Pupils equally contracted or dilated.
5. Examination of urine may not reveal anything abnormal.

6. The features are of a bloated appearance.

#### *Alcoholic Stupor.*

1. No paralysis.

2. Tremors are confined to the head and arms and occur chiefly in morning.
3. Face has usually a bloated appearance.

4. There is no bloated appearance. There is probably a history of an alcoholic debauch.

#### *Alcoholic Stupor.*

1. Face cool and moist.

2. Respirations normal or slightly accelerated. Gurgling may be heard.

3. Absence of distinct convulsive movements.

4. Examination of the urine may not reveal anything abnormal.

5. Face may present only slight tenancy and a bloated appearance.

#### *Alcoholic Stupor.*

1. Pulse rapid and bounding.

2. Respirations shallow.

3. Pupils equally contracted or dilated.

4. Temperature may be normal.

5. There may be no frothing at mouth.

#### *Alcoholic Stupor.*

1. Muscles relaxed.

2. Tremors confined to head and arms and may be removed by giving a dose of alcohol.

3. Speech usually of a brusque character.

4. No incontinence.

#### *Alcoholic Stupor.*

1. Muscles relaxed.

2. Tremors confined to head and arms and may be removed by giving a dose of alcohol.

3. Speech usually of a brusque character.

#### *Opium Poisoning.*

1. Skin dry and warm.
2. Respirations slow, deep, and full.
3. Pulse slow, strong, and full.
4. Pupils extremely small and contracted (pin point).
5. There is profound coma and it may be impossible to awaken patient before death supervenes.

6. Absent in opium poisoning.

#### *Strychnine Poisoning.*

1. Muscles in a state of tetanic rigidity.
2. There are tonic convulsions of the entire body, which may be in a condition of orthopnea, apnoea, or rarely emprosthotonus.

3. Respirations scarcely audible on account of spasm of respiratory muscles.

4. Eyes open and fixed, pupils greatly dilated.

5. Examination of urine may reveal presence of strychnine.

6. There is a clonic grin, so called risus sardonius.

#### *Chronic Lead Poisoning.*

1. There may be paralysis of certain groups of muscles, the brachial, carpal (wrist drop), and sometimes the peroneal muscles.

2. Tremors more diffuse and not limited to morning.

3. Face presents an intense anemia, so called saturnine cachexia.

4. Blue line at margin of gums.

5. The knowledge of the individual's occupation usually leads to the diagnosis of plumbism.

#### *Belladonna Poisoning.*

1. Face, flushed and dry, sometimes presents an erythematous rash.

2. Respirations extremely depressed.

3. There is usually a rise in temperature.

4. Presence of convulsive seizures.

5. Examination of the urine may show presence of belladonna.

6. There are distinct lines of malar rash extending from malar bones to angles of jaw, giving malar-malar expression.

#### *Stupor.*

1. Pulse rapid and full.

2. Respirations labored and deep.

3. Pupils extremely contracted.

4. Temperature range is usually very high.

5. In severe cases, there is profound coma lasting from half an hour to twelve or twenty-four hours, and followed by either death or recovery.

6. Skin is flushed and hot.

#### *Fever.*

1. Temperature high.

2. There is a history of exposure to twenty-four hours, and if the patient is not recovered, it is a case of malarial fever.

3. There is a history of exposure to twenty-four hours, and if the patient is not recovered, it is a case of malarial fever.

4. There is a history of exposure to twenty-four hours, and if the patient is not recovered, it is a case of malarial fever.

5. There is a history of exposure to twenty-four hours, and if the patient is not recovered, it is a case of malarial fever.

6. There is a history of exposure to twenty-four hours, and if the patient is not recovered, it is a case of malarial fever.

7. There is a history of exposure to twenty-four hours, and if the patient is not recovered, it is a case of malarial fever.

4. Temperature normal.

5. No strabismus.

6. *Alcoholic Stupor.*

1. Pulse rapid and feeble.

2. Respirations normal or slightly accelerated.

3. Temperature usually normal.

4. Face moist and cool.

5. Lungs may be normal.

6. Eyes dull and apathetic.

7. *Alcoholic Stupor.*

1. Pupils equally contracted, unless patient is aroused.

2. No paralysis.

3. There may be no head injury present.

4. Unconsciousness incomplete.

5. *Alcoholic Stupor.*

1. Skin cool and moist.

2. Temperature may be normal.

3. Pulse strong at first, finally feeble.

4. Alcoholic odor in breath.

5. Patient may be of strong and robust constitution.

6. Stupor not preceded usually by any special symptoms.

7. Sugar may be absent from urine.

8. *Alcoholic Stupor.*

1. Pulse rapid and feeble.

2. Respirations may be normal.

3. Pupils equally contracted, unless patient is aroused.

4. Ophthalmoscopic examination may not show anything abnormal.

5. Examination of the urine may not disclose any abnormality of the renal organs.

6. Only the strong odor of liquor may be detected in breath.

7. Presence of urea in blood.

8. Dropsy may be absent.

9. Coma not so pronounced and may be followed by intervals of consciousness.

10. No paralysis.

11. Temperature may be normal.

12. *Alcoholic Stupor.*

1. Face shows slight pallor and is moist and cool.

2. Respirations nearly normal.

3. Examination of the urine may not disclose any abnormality of renal function.

4. There may be no convulsive seizures.

5. Unconsciousness incomplete.

6. There may be no frothing at mouth.

7. Attacks are of longer duration.

8. *Alcoholic Stupor.*

1. Pulse rapid, compressible, and weak.

2. Skin cold and clammy.

3. Respirations normal or slightly lowered.

4. Pupils equally contracted.

5. Respirations normal or suppressed.

6. Unconsciousness incomplete.

7. No facial paralysis.

8. No incontinence.

9. *Alcoholic Stupor.*

1. Muscles relaxed.

2. Tremors confined to head and arms and may be removed by giving a dose of alcohol.

3. Speech usually of a brusque character.

4. No incontinence.

5. *Alcoholic Stupor.*

1. Muscles relaxed.

2. Tremors confined to head and arms and may be removed by giving a dose of alcohol.

3. Speech usually of a brusque character.

4. No incontinence.

5. *Alcoholic Stupor.*

1. Muscles relaxed.

2. Tremors confined to head and arms and may be removed by giving a dose of alcohol.

3. Speech usually of a brusque character.

4. No incontinence.

4. High temperature.

5. Strabismus.

6. *Alcoholic Stupor.*

1. Pulse full and bounding.

2. Respirations greatly accelerated.

3. Temperature high.

4. Face warm and flushed.

5. Well marked physical signs of consolidation may be detected.

6. Eyes bright.

7. *Cerebral Compression.*

1. Pupils dilated and fixed, or unequal.

2. Paralysis.

3. Fracture of some part of cranial vault may be detected.

4. Unconsciousness complete.

5. *Diabetic Coma.*

1. Skin hot and harsh.

2. Temperature usually abnormal.

3. Pulse rapid and thready and greatly lowered tension.

4. Peculiar sweetish acetone odor to breath.

5. Extreme emaciation of patient.

6. Diabetic coma is usually preceded by extreme dyspnea, syncope, nausea, vomiting, and headache.

7. Sugar is present in large quantities in urine also acetonuria, and acetonemia.

8. *Uraemic Coma.*

1. Pulse rapid and full, and minus tension.

2. Respirations greatly accelerated.

3. Pupils irregular.

4. Examination of the eye ground usually determines the presence of albuminuric retinitis.

5. Examination of the urine demonstrates the presence of nephritis.

6. Heavy, fetid, urea like odor in breath.

7. Presence of urea in blood.

8. Presence of dropsy.

9. Coma is profound.

10. There may be a monoplegia or hemiplegia.

11. Temperature usually elevated.

12. *Epileptic Coma.*

1. Face, at first pallid, rapidly develops a dusky or livid hue, and there is profuse perspiration.

2. Respirations suppressed and scarcely audible.

3. Albumin may or may not be present. There is often excess of indican in urine.

4. The body assumes a position of tetanic rigidity, followed by clonic convulsions which are succeeded by coma.

5. Unconsciousness complete.

6. There is a frothy saliva which may be blood stained, due to patient having bitten his tongue.

7. Attack is usually of short duration, and patient returns to consciousness immediately.

8. *Apoplectic Coma.*

1. Pulse full, strong, and bounding.

2. Skin hot and dry.

3. Bodily temperature greatly increased.

4. Pupils unequal.

5. Respirations stertorous and one sided in inspiration.

6. Complete unconsciousness.

7. Facial paralysis.

8. Hemiplegia.

9. *Unconsciousness.*

1. Muscles stiff and presence of contractures.

2. Tremors more diffuse and subside when muscles are at rest, so called voluntary tremor.

3. Scanning speech.

4. No incontinence.

5. *Paralytic Coma.*

1. All four extremities equally involved, and head is not usually involved.

2. Tremors removed by giving alcohol.

3. Muscles are usually flaccid.

4. Face presents a dull and beset appearance.  
*Alcoholic Stupor.*

1. No ptosis or strabismus.  
2. No Argyl Robertson pupil.  
3. Reflexes normal or exaggerated.

4. Waddling gait.  
5. No hemiplegia.

*Alcoholic Stupor.*

1. Delirium is of a restless, noisy character, and is characteristic.

2. Tremors confined to head and arms.

3. Tremors allayed or removed by giving alcohol.

4. Attacks of shorter duration, and are separated by intervals of sanity.

5. Pupils equally contracted.

6. Mental condition temporarily improved by dose of alcohol.

1. Pulse rapid and feeble.  
2. Respirations normal or suppressed.

3. Patients are usually males.  
4. Unconsciousness more complete, and return to consciousness is slower than in hysteria.

5. No paralysis.  
6. No contractures.  
7. No monocular diplopia.

8. Convulsions uncommon.

2. Tremors cease during sleep and persist when aroused at rest.

3. There is rigidity of all the muscles of the body.

4. Face is expressionless and mask like.

1. Ptoxis and strabismus.  
2. Argyl Robertson pupil.  
3. Loss of knee jerk.

4. Stepping gait.  
5. There may be hemiplegia.

1. Delirium of grandeur or exaltation more marked.

2. Tremors more diffuse.

3. Tremors increased and made worse by alcohol.

4. Attacks of longer duration.

5. Pupils irregular and presence of Argyl Robertson pupil.

6. Mental symptoms made worse by alcohol.

1. Pulse strong and full.  
2. Respirations extremely rapid.

3. Patients are usually females.  
4. Unconsciousness is only apparent, and return to consciousness is rapid.

5. There may be paralysis.  
6. Contractures present.

7. Monocular diplopia is pathognomonic in absence of structural defect.

8. There may be tonic or clonic convulsive seizures.

teria, or sunstroke; it must be gradual; it may attend any of the acute infections. It is also symptomatic of narcotic poisoning, diabetes, uræmia, the organic brain lesions, and meningitis.

In particular, uncomplicated alcoholic stupor is seldom difficult of diagnosis. We are all familiar with the classic picture of alcoholic stupor—the cold, clammy skin, the feeble, rapid pulse, the heavy stertorous breathing, the great muscular relaxation, moderately dilated pupils, subnormal temperature, oftentimes the alcoholic breath, the staggering gait, and incoherent muttering.

From this we must distinguish:

Apoplexia.—We may obtain the history of a former attack; we are guided by its usual association with arteriosclerosis; the characteristic full, bounding pulse; a unilateral paralysis, or aphasia; contracted pupils; slow, stertorous breathing; cyanotic mucous membranes; occasional loss of the organic sphincter control; a valuable negative sign is the absence of any external trauma.

Thrombosis.—Arteriosclerosis, as a rule; slow onset; characteristic weak pulse; paralysis depending on area involved.

Embolism.—Usually in second or third decade of life; associated with valvular cardiac disease; onset sudden; course afebrile; paralysis, as in thrombosis.

Concussion.—History is important as to fall, etc.; pupils equally contracted and responsive to light; no paralysis; weak and rapid pulse; immediate onset of stupor.

Compression.—Usually evidence of fractured skull; slow onset of stupor; paralysis, local or general; pupils irregular, without light reaction.

Uremia.—Local or general edema; cyanosis; miosis; blood pressure high; no sign of trauma or paralysis; muscular twitchings or convulsions; microscopic and gross examination of urine is final.

Hysteria.—Usually young female; stupor may alternate with hysterical crying; examine for presence of hysterical stigmata paresis or paralysis, anæsthesia, or hyperæsthesia, globus hystericus, etc.; tonic or clonic spasms; catalepsy.

Epilepsy.—History of former seizures; bitten tongue; frothy mouth; urinal discharges; injury from a fall; pupil, normal and reactive.

Diabetes.—Suspect this if case is a young person; usually "air hunger," preceded by nausea or vomiting; sweetish breath; examine urine for sugar and acetone.

Sunstroke.—Flushed, pungent skin; rapid pulse; hyperpyrexia; dyspnea.

Heat exhaustion.—Cool skin; feeble pulse; no fever; mild dyspnea.

Opium.—Extremely slow respirations, four to the minute; characteristic "pin point" contracted pupils; pallor; muscular relaxation; feeble pulse.

Chloral.—Pallor; cold, clammy perspiration; thready pulse; slow, labored respiration; muscular relaxation; subnormal temperature.

Ptomaine.—History of case is valuable; onset fairly sudden; gastrointestinal symptoms leading to collapse.

Meningitis.—History is important; Kernig's sign or Babinski's sign along with the evidence from fundus bar puncture; paralysis (especially eye); opisthotonos; exaggerated reflexes; severe headache.

Dr. William A. L. Styles, of Montreal, Can., observes.

Stupor is a partial loss of consciousness, a profound slumber from which it is possible to awaken the patient only with great difficulty and by importunate solicitations (Butler).

It occurs in many conditions and presents various concomitant symptoms depending on the etiological factor. Alcoholic stupor is to be distinguished from several conditions closely resembling it; the diagnosis of this condition *per se* seldom presenting untoward difficulties, but occasionally mistaken diagnoses result, as sometimes upon it is superadded a much graver condition.

In considering any case of stupor it is well to follow a certain routine in our method of examination. The physician should look to the (a) skin for cutaneous temperature, eruptions, etc.; (b) head for evidences of trauma, depressions, etc.; (c) face for unilateral facial paralysis indicating some unilateral cerebral lesion (hemorrhage, embolism, etc.); (d) eyes for bilateral myosis, nonresponsive on shading the pupil (as, in cerebral lesions or narcotic poisoning); if on endeavoring to upraise the lids there results a quivering muscular resistance and the eyeballs are directed upwards, suspect hysteria; (e) mouth and tongue for bites or froth (epilepsy) and odor; (f) extremities; look for spastic, or flaccid, paralysis; it may happen that on superficial examination all the extremities are apparently paralyzed, but closer investigation reveals a greater amount of relaxation (i. e., "limp") on one side.

The history of the case, if procurable, and, at times, the character of the surroundings in which the patient is found, will materially assist in the diagnosis.

In general, we may say that suddenly occurring stupor is indicative of epidemic cerebrale disease.

Dr. F. H. Smith, of Leesburg, W. Va., has prepared the following table, which he entitles:  
*Recognition of Alcoholic Stupor.*

	ALCOHOLISM	OPIMUM POISONING	POISONING BY SOME MEMBER OF THE ALKALOID GROUP	COCAINE POISONING	CHLORAL POISONING	URÆMIA
1. Manner of Onset, Degree, and Character of Stupor	It is almost impossible to arouse patient, heavy sleep, can be who protests incoherently, to drop off full back into many again into stupor. Patient comes deeper and Police apply ready to deeper, until finally hand test, tapping on forehead, coma en- tect with bill of fingers, from which he aroused, man is only cannot be aroused, drunk	This group rarely produces extreme stu- por, though he is un- conscious of anything about him.	More like the bella- donna group than al- cohol, so far as stupor is a symptom. Rarer than stupor, though syncope and convul- sion may appear, more often incoherence.	At first normal to deep sleep; finally deep coma.	At times, a convul- sion precedes, after which a coma ensues suddenly, and is pro- found. Or the stupor may develop without convul- sion gradually, usually becoming pro- found.	
2. Delirium, and Hallucinations	Incoherence of speech, or even active period of pleasant delirium and hal- lucinations of speech and before the deep- aearing, common com- of delirium symptoms. A little of these symptoms intensi- fied in delirium tremens; and in extreme alcoholism more or less permanent delu- sions, etc., are com- mon.	There may be gar- rulous, incoher- ent, uncontrollable laughter or weeping, busy delirium, even mania, with hallucina- tions and delusions, these are common symp- toms.	Many patients be- come garrulous and incoherent. In chronic poisoning, the mental failure, delusions and hallucinations of a disagreeable nature are much like those of chronic alcoholism.	May be present.		
3. The Face	Usually flushed, often slightly cyan- otic; sometimes (ex- treme cases) pallid. Fullness of vessels of face and neck. Usually evidence of habit from "bloated" ap- pearance. No sign of facial paralysis.	Suffused and dusky- dened; then red- scarlatinoform erup- tion and cyanotic, cyanosis progressing as coma and finally pale and livid	Face flushed, often scarlatinoform erup- tion	White and livid.	May present swollen, "doughy," trans- lucent pallor of renal disease, especially about the eyelids.	
4. The Pulse	In the earlier stages a moderate degrees, rather rapid, full, strong; later, rapid, small, feeble.	Slow and full; ter- minal stages of pro- found poisoning; rap- id, small and feeble.	Markedly quick- ened.	Quickened, and in- collapse or stupor en- sues, very much en- feebled.	Perhaps, a little slowed at first, though soon rapid, thrifty, shuttle like, or lost at wrist.	Usually very slow, apt to be of high ten- sion; artery hard and unyielding and heart may be hypertrophied.
5. The Respiration	Normal frequency, deep, at times some- what irregular.	Slow, 12 to 4 a minute, at first deep and stertorous; later, shallow.	Slow and full, be- coming quicker and later, shallower, and finally even dyspnoic.	Quickened; if cool labored, later shallow and feeble.	At first, slow and deep, later shallow and feeble.	Nearly always very deep, sometimes quickened, at times hissing. Cheyne- Stokes' type not rare, at times, difficult (uræmic asthma).
6. The Temperature	Usually subnormal.	Normal or subnor- mal.	More or less ele- vated.	Usually subnormal.	Subnormal.	Nonconvulsive type, subnormal. (91° to 95° F.). Convulsive type, very high, at times 108° F. May be chills followed by fever and collapse.
7. The Skin	Usually cool and moist.	Warm and dry, un- til sweat of approach- ing death.	Dry and hot, scar- lat eruption may be present.	In collapse, skin cold, cyanotic, clammy.	Body, especially forehead and hands, covered with a cold sweat.	General pallor, skin dry. Edema may be general, or confined to face and limbs.
8. The Pupils	Constricted, or equal of normal size, or slightly dilated.	Pupils equally con- tracted to pin point size.	Conjunctivæ inject ed, lids reddened and itching; pupils equal, extreme dilatation.	Pupils dilated.	Pupils, for a short while, contracted soon, widely dilated.	Eye examinals should be examined (albuminuric retinitis).
9. The Odor of the Breath	Not other ingested or broken down of alcohol and the sour smell of "drunkard's stomach." (It is to be remembered that a strong hint be the ex- isting cause of some more serious trouble, this rather, than the odor of alcohol, which is usually given the strict- est attention by stander, and hence, the odor of alcohol, which is usually given the strict- est attention by stander.)	Odor of opium, or some of its prepara- tions, though not re- covered when an opium is used.	The odor of the drug may be recog- nized (unless its alkalo- id was used). Ex- treme dryness of mouth, tongue and throat, an early sym- tom.	Mouth and throat dry.		Tongue and lips may have been in- jured by teeth, if convulsive. Urinous or ammonia like odor, which is strongly sug- gestive.

ALCOHOLISM	OPIMUM POISONING	POISONING BY SOME MEMBER OF THE BELLADONNA GROUP.	COCAINE POISONING	CHLORAL POISONING	URÆMIA
May show some slight injury—a cut or a bruise—such as may have been gotten in a fall or scuffle.					May have struck head in a convulsion.
10. The Head					
Abstinent.					At times, a pseudo-hemiplegia, transient and inexplicable.
11. Paralysis					
	Infrequent, though some muscular twitching is common.	Rare	Tremors and slight convulsive movements common. Later, powerful tonic or clonic convulsions may supervene.		Initiate one type of uræmia, the convulsive type, and may recur irregularly during the coma.
12. Convulsions					
13. The Urine and Bladder	In a complicated case, urine apt to be concentrated. Bladder liable to be distended by retention of urine, or bladder may act involuntarily.	Frequently urine is voided at early period, afterward constant desire to micturate and inability to do so.		Eliminated with urine as chloral and urochloralic acid, giving the reaction for sugar with Fehling's test.	Urine usually much diminished, or even suppressed. Shows considerable albumin and casts. Urea elimination low.
14. The Head	DEEPER COMA	APOPLECTY	GRAND MAL TYPE OF EPILEPSY	SUNSTROKE	"CONCUSSION," OR LACERATION OF THE BRAIN
			May have been injured by fall at onset of convulsion, or several old scars of injuries of former attacks. Or, on the other hand, the cause of the epileptic attack may be discovered as an old depressed fracture.	Usually an injury or face will usually show sign of injury, ecchymosis, cut area of edema, though stunning force may have been indirectly received	COMPRESSION OF THE BRAIN, BY (1) DEPRESSOR FRACTURE; (2) MENINGEAL HAEMORRHAGE; (3) ABSCESS; (4) TUMOR
15. The Head		Usually hemiplegia, as demonstrated by one side being tossed about, other remaining motionless; or by flitting limb, when it there may, however, will fall more flaccid than the other.	Several facts are to be noted: (1) Uncomplicated idiopathic epilepsy is not attended by true paralysis; (2) Hitting limb, when it there may, however, will fall more flaccid than the other.	Usually an injury or face will usually show sign of injury, ecchymosis, cut area of edema, though stunning force may have been indirectly received	Usually an injury to head discoverable in the first two causes of compression mentioned, though injury to skull may be basal and not appear on the surface.
16. The Head		Violent delirium may be a part of the picture, rarely com-	Convulsions rare, although there may be convulsive movements of some parts at onset.	There may be repeated convulsions	Occasionally, though by no means the rule
17. The Head			Convulsions, preceded by clonic spasms, whether they be general or local.

## Therapeutical Notes.

**Aphrodisiacs and Antaphrodisiacs.**—From Pron's *Formulaire synthétique de médecine* (Paris: J. Rousset) we take the following prescriptions for aphrodisiac and antaphrodisiac preparations:

### Aphrodisiacs:

A warning is given against the use of preparations of cantharides, which are irritating to the digestive tract and the genitourinary organs.

R Tincture of benzoïn, {  
Tincture of canella, { .....āā 5i.  
Tincture of vanilla, }  
M. Sig.: Twenty drops to one teaspoonful three times a day.

R Compound spirit of ether {  
Tincture of canella, { .....āā 3i;  
Tincture of nux vomica, }  
Tincture of vanilla, } .....M̄ xv.  
M. Sig.: Eight to ten drops three times a day.

R Phosphoric acid, {  
Pulverized cinchona bark, { .....āā gr. xv;  
Pulverized camphor, .....gr. ivss;  
Extract of cascarrilla, .....q. s.  
M. ft. pil. No. xxiv.  
Sig.: One to three pills four times a day.

R Zinc phosphide, .....gr. iss.  
Ft. pil. No. xii.  
Sig.: One to two pills three times a day.

R Yohimbine (or yohimbine hydrochloride), ...gr. ⅞;  
Distilled water, .....3iiss;  
Dissolve.

For hypodermic injection. Five to fifteen minims to be injected at night in the region of the thigh. After a few days the treatment should be suspended for one or two days.

R Solution of yohimbine hydrochloride (1 per cent), .....3ii.  
Sig.: Five to ten drops three times a day

(This drug is said to lose its effect after a few weeks of use.)

R Extract of cannabis indica, {  
Extract of nux vomica, { .....āā gr. iv;  
Extract of aloes, .....gr. xii.  
M. ft. pil. No. xii.  
Sig.: One three times a day.

### Antaphrodisiacs:

R Monobromated camphor, .....gr. iv.  
Ft. capsula No. i  
Sig.: One capsule three or four times a day.

R Monobromated camphor, .....3iiss;  
Alcohol, .....3iiss;  
Glycerin, .....3iiss;  
M. Sig.: One teaspoonful once or thrice daily.

R Aqueous extract of hyoscyamus, .....gr. xii  
M. ft. pil. No. xii.  
Sig.: One pill three or four times a day.

R Lupulin, .....gr. xii.  
Ft. capsules No. xii.

R Potassium bromide, .....3v;  
Distilled water, .....adde 3v.  
Sig.: One table spoonful morning and evening.

**Calcium Chloride in Albuminuria.**—Renon, in a communication to the Société de Thérapeutique de Paris (*Journal of the American Medical Association*, February 20, 1908), says that calcium chloride has proved efficacious in arresting albuminuria of various origins, without any supplementary measures or repose. He gives one and one half grains for five or six days, gradually increasing the dose if necessary to seven and one half grains, and keeping

up the treatment for a month if the albuminuria persists. A number of patients were cured by this means after the complete failure of dietetic measures and prolonged repose. In half the cases treated the albuminuria vanished entirely. In another fourth no effect was apparent, or the albuminuria became aggravated, which occurred in a few instances.

**The Treatment of Erythematous Eczema.**—Shoemaker (*Medical Bulletin*, February, 1908) recommends as a local application for erythematous eczema the following ointment:

R Salicylic acid, .....3ss;  
Resorcin, .....3ss;  
Compound tincture of benzoïn, .....3ii;  
Zinc ointment, .....3i;  
Ointment of rose water, .....3i.

Misce, ft. unguentum.

Sig.: Apply locally twice daily.

Internally the following pill is directed to be taken for its alterative effect on the glands and as a digestive corrigent:

R Silver nitrate, {  
Extract of hyoscyamus, { .....āā gr. 14.  
M. ft. pillula No. i.

Sig.: One pill to be taken half an hour before each meal.

**Nervous Palpitation.**—As a sedative Lemoine and Gérard (*Le progrès médical Belge*, January 1, 1908) recommend quinine valerianate to be given in a cachet every morning in combination with sodium bicarbonate, or camphor, in the following combination:

R Quinine valerianate, .....gr. iiiss;  
Sodium bicarbonate, .....gr. vii.

M.  
R Quinine valerianate, .....gr. iiiss;  
Camphor, .....gr. vii;  
Pulverized valerian, .....gr. iii.

M.

**Corrosive Sublimate in Pill Form for Syphilis.**

—In the treatment of syphilis Guiard (*Journal de médecine de Paris*) gives corrosive sublimate in pills of the following composition:

R Extract of opium, .....3ss;  
Glycerin, .....3iil xv;  
Pulverized gluten, .....3iv;  
Corrosive sublimate, .....gr. xv;  
Sodium chloride, .....gr. xv;  
Water, .....3iiss.

Dissolve the extract in the glycerin, add the gluten, followed by the corrosive sublimate previously dissolved in the water with the aid of the sodium chloride, and make 200 pills.

Sig.: One pill four times a day.

**Medicinal Treatment of Graves's Disease.**—

Thomson (*American Journal of the Medical Sciences*, March, 1908) favors the medicinal treatment of Graves's disease. He recommends to every patient thirty grains of sodium phosphate, to be taken at the beginning of each meal, and a blue pill or other mercurial laxative to be taken twice a week. A course of intestinal antiseptics is then recommended, to be kept up for months at a time. He usually begins with sodium salicylate and sodium benzoate, of each ten grains, an hour after each meal. He prescribes for administration at bedtime a capsule containing naphthalene three grains and sodium benzoate six grains. After a time he substitutes a capsule containing phenol bisulphite and sodium benzoate with five grains of which two should be taken an hour after meals. The principle

of these remedies as intestinal antiseptics being understood, every physician can, Dr. Thomson says, vary the prescription as he finds best.

**Lord Lister's Formula for Chromic Catgut.**—The following directions for preparing what is known as chromic catgut were communicated by Lord Lister to the *Lancet* for January 10th:

"The preparing liquid must be twenty times the weight of the catgut. So for forty grains of catgut 800 grains of preparing liquid are required. It is made by mixing two liquids—namely, the chromium sulphate liquid and the sublimate liquid.

"The sublimate liquid is:

Corrosive sublimate, ..... 2 grains;  
Distilled water, ..... 320 grains.

"The sublimate may be dissolved by heat, but the solution must be used cold.

"The chromium sulphate liquid is prepared thus:

Chromic acid, ..... 4 grains;  
Distilled water, ..... 240 grains.

"Add to this as much sulphurous acid (P.B. solution)<sup>1</sup> as gives a green color. If more is added, the color becomes blue, which shows that rather too much sulphurous acid has been used. It is well to reserve a few drops of the chromic acid solution, to be added after the blue color has just appeared and restore it to green. Then enough distilled water is added to bring the green liquid up to 480 grains. Then add the sublimate liquid.

"The catgut is kept for twenty-four hours in the preparing liquid and is then dried on the stretch. (N. B.—It is essential that the chromic acid and sulphurous acid solutions be mixed before the sublimate solution is added).

"Catgut prepared in this way remains actively antiseptic in its substance for an indefinite period, as was shown by the following experiment: Some slender hanks prepared three years previously, weighing 207 grains, chopped into short segments, were placed in a small mortar and treated with enough distilled water to cover them, 2,000 grains being required for the purpose. The gut was then pressed firmly with a pestle and the same was afterwards done three times at intervals of about three hours. The gut and water were then transferred to a stoppered bottle for seventeen hours, when the liquid was poured off and filtered, being clear and almost colorless. The germicidal property of the infusion was carefully tested by the late Dr. Allan Macfadyen. In spite of the large amount of water used in preparing it, he found that it destroyed the *Streptococcus pyogenes* in a quarter of an hour; when diminished to half its bulk by evaporation *in vacuo* it killed *Staphylococcus pyogenes aureus* in half an hour; and when further reduced by one half it deprived the resisting spores of anthrax of vitality in two hours, although the amount of the liquid was still about twice that of the catgut to which it was applied.

**Harrington's Solution.**—This solution, which originated with Dr. Francis B. Harrington, of Boston, is regarded by surgeons (*New York Medical Journal*, February 15, 1908) as one of the best and most destructive antiseptic fluids for suppurating

wounds, and for general use in the operating room. Summers (*loc. citat.*) says it has been proved experimentally and clinically that it kills all the common germs met in surgical practice in from twenty seconds to a minute, and it is not caustic. Besides its antiseptic property it possesses the power, when applied to a raw surface, to produce a copious discharge of serum, thus aiding the washing away of noxious elements from the wound. The formula for the solution is as follows:

B Corrosive sublimate, ..... gr. xv;  
Hydrochloric acid, ..... fl. ʒiiss;  
Water, ..... fl. ʒxii ʒvi;  
Alcohol, ..... fl. ʒxxvii.

Solve.

Sig.: Harrington's Solution.

**Mixtures for Bronchial Asthma.**—Rossbach (*Therapeutische Rundschau*) recommends the following mixtures as being efficacious in the treatment of bronchial asthma, and acute and subacute laryngitis:

I.

B Apomorphine hydrochloride, ..... gr. ʒ4;  
Codeine phosphate, ..... gr. i to gr. ii;  
Hydrochloric acid, ..... fl. ʒviii;  
Simple syrup, ..... ʒv;  
Distilled water, ..... ad ʒvi.  
M. et Sig.: One tablespoonful every three hours.

II.

B Apomorphine hydrochloride, ..... gr. iiii;  
Codeine phosphate, ..... gr. viii;  
Hydrochloric acid, ..... gtt. i;  
Hot distilled water, ..... ad ʒv.  
Dissolve. Sig.: Ten drops every two hours.

**Tannic Acid in the Treatment of Dermatitis Venenata and Eczema Vesiculosum.**—The drug which in the hands of Kinnaman (*American Journal of Dermatology*, February, 1908) has given most uniform success in allaying the inflammation of the skin and checking the serous discharge from the ruptured vesicles or blebs in cases of dermatitis venenata and eczema vesiculosum is tannic acid. It may be used in either of three ways, i. e., as a dusting powder, as a lotion in aqueous solution, and incorporated with a base as a salve. If the case is seen early and only a few of the vesicles have ruptured he uses one or other of the following combinations:

I.

B Tannic acid, ..... ʒi;  
Talc, ..... ʒii.  
M. Sig.: As dusting powder.

II.

B Tannic acid, ..... ʒi;  
Thymol iodide, ..... aa ʒii.  
M. Sig.: As dusting powder.

The parts are to be protected with cotton and bandages.

When there is a moderate degree of serous discharge the following applications have proved most efficient:

I.

B Tannic acid, ..... ʒss to ʒi;  
Zinc oxide, ..... ʒi;  
Ointment of rose water, ..... ʒi.

M

II.

B Tannic acid, ..... ʒss;  
Thymol iodide, ..... aa ʒss;  
Zinc oxide, ..... ʒss;  
Ointment of rose water, ..... ʒi.

M

<sup>1</sup> The following is the formula for the preparation of this solution: It is identical with the one given by Rossbach.

office or express money order payable to the A. R. Elliott Pub-  
lishing Co., or by registered mail, as the publishers are not  
responsible for money sent by unregistered mail.

Entered at the Post Office at New York and admitted for  
transportation through the mail as second class matter.

NEW YORK, SATURDAY, MARCH 7, 1908.

## THE PUBLIC HEALTH AND MARINE HOSPITAL SERVICE.

We have received the *Annual Report of the Surgeon General of the Public Health and Marine Hospital Service of the United States for the Fiscal Year 1907*. It is an octavo volume of 146 pages. For five years now the bureau, formerly the Marine Hospital Service simply, has been charged with the great additional duties incident to its prominent participation in the general sanitary work of the nation. These duties have been well performed, and the surgeon general is justified in saying that "Congress has established a public health bureau with a broad foundation." The work, as is well known, extends not only to our outlying possessions, but also to the foreign countries from which our immigrants are derived. Typhoid fever has been profitably investigated in the District of Columbia, in Savannah, Ga., and in Charlotte, N. C., and some months ago the bureau published a voluminous and useful report on this subject. In conjunction with the Bureau of Animal Industry and the Bureau of Chemistry of the Department of Agriculture and the health department of the District of Columbia, the bureau has made a minute investigation of the milk industry, and we are informed that its report will soon be published. Surgeon General Wynman assures us that, as a result of the bureau's supervision of vaccines and curative serums, the tetanus antitoxine now produced is worthy of complete confi-

dence, both as to purity and as to potency, though before it was weak and variable. An account of the plague investigation in San Francisco is to be included in the next annual report.

The other activities of the bureau have been connected with the Jamestown Exposition, making provision for the investigation of leprosy in the Territory of Hawaii, the national quarantine, the medical inspection of immigrants (1,285,349 inspections), sanitary conferences with State boards of health, and, of course, the operation of the marine hospitals. It will be seen that the bureau's work is onerous, and it is gratifying to find, as we do in this report, abundant evidence that it is performed efficiently.

## ALBUMINURIA AND THE ITCH.

Of course, we long ago gave up the old notion of the "repercussion" of skin diseases and the dire results of such an occurrence, but it is interesting to note that it lingered rather late in the nineteenth century, as we are reminded in an article by Dr. J. Nicolas, clinical professor, and Dr. A. Jambon, chief of clinic, of the Antiquaille Clinic for Cutaneous and Venereal Diseases of the University of Lyons, published in the February number of the *Annales de dermatologie et de syphiligraphie*. But this is not all that our authors do; they confirm the observations of a number of modern clinicians to the effect that albuminuria is a frequent accompaniment of scabies, and they discuss in a very illuminating way the relations of the renal disorder to the skin disease.

They show that the connection between scabies and albuminuria is not merely that of coincidence, that it is not to be explained by the assumption that the subjects were already affected with renal disease and the itch was simply a casual acquisition, though they admit that persons who have been subjected to the ordinary causes of nephritis are more likely than others to be attacked with it in the course of scabies. They do not approve of the theory that the kidney disturbance is due to interference with the cutaneous functions, whereby undue work is forced upon the kidneys, as when the skin is extensively burned or covered with some impermeable material, for they have found that albuminuria occurs in many instances in which the scabies is not widely diffused over the skin.

The theory that the renal affection is due to the penetration of pyogenic organisms into the blood, with the production of toxæmia, does not seem to the authors adequate to account for what takes place, because in a large proportion of the cases observed by them the lesions were not pustular.

they do, however, admit the possibility of such a mode of production in pustular cases. They look with favor, too, upon the hypothesis that the cutaneous irritation may of itself give rise to the kidney trouble through the mediation of the nervous system. There would, however, be nothing peculiar to scabies in that; many cutaneous affections are accompanied by an amount of irritation equal to that of the itch, and involving as great an extent of skin. The authors do not altogether reject the idea that the sarcoptes itself may generate a poison that gains entrance into the blood. They regard the question of the manner in which scabies gives rise to albuminuria as by no means satisfactorily settled. They announce their intention of continuing their investigation and of communicating a further article on the subject, which is well worthy of study.

### UNCINARIASIS IN PUERTO RICO.

The third report of the men engaged in the attempt to reduce or to eradicate infection with *Necator americanus* in Puerto Rico shows that the infection is most common in persons from fifteen to twenty-nine years of age, and that all classes of the population are hosts of the parasite. The infection is often acquired by cultivating flower gardens.

As in former reports, the commission includes the results of scientific study of the disease and its pathology. Dr. Gutiérrez, the chairman of the commission, has succeeded in showing that *Ankylostoma duodenale* is present in Puerto Rico, as well as *Necator americanus*. The opinion is again put forth that infection takes place through the skin, the passage of the larvæ through the skin producing a papulopustular dermatitis, called *mazamorra* by the peasants.

The commission advances the theory that the anæmia of uncinariasis is due to hæmolysis, and not to hæmorrhage, as was formerly believed. Their reasons for this belief are the facts that bloody stools are extremely rare and that the intestine of the parasite contains principally epithelium and very few red blood cells. They have made no studies of the stools for occult blood, dismissing the subject with the statement that should occult blood be found, it would not explain the severe anæmia, on account of the small quantity of blood indicated by that test.

We would point out that the test for occult blood is not a quantitative, but a qualitative test. It is quite possible that a considerable amount of capillary hæmorrhage, enough when continued for long periods of time to produce severe anæmia, may occur high in the jejunum and in the duodenum,

and that by the time the fæces are passed the blood would be so altered as to be demonstrable only by the test for its hæmoglobin derivatives. Also it is conceivable that blood taken into the intestine of the parasite would undergo alterations sooner than epithelial cells, and so distinct erythrocytes be unrecognizable with the microscope.

The commission has studied the condition of the urine in twenty-four cases. Albumin with casts is found to be common. This is considered to be indicative of a degenerative change in the kidneys and not of an inflammation. The albumin is present in very small quantities, requiring the application of the acetic acid and potassium ferrocyanide test for its demonstration. It is well known that this test will give a positive reaction with mucin and with fibrinogen. In order to infer the presence of degenerative or inflammatory changes in the kidney we believe that serum albumin in sufficient quantities to be detected by the beat and nitric acid tests, or by the cold nitric acid test, should be present. It appears to us that the condition present is one of renal irritation only, which is sometimes made worse by the administration of thymol or beta naphthol. There is much interesting matter in the report, including an admirable photomicrograph of the parasite *in situ*, made by Dr. W. M. Gray, of the Army Medical Museum.

### A NEW NEW YORK STATE COLONY.

The march toward organized and comprehensive care of the dependents in New York State has gone steadily forward. The State care of the insane and the gradual coordination of the State hospitals marked one of the greatest epochs in the history of such movements in the State. Its great success, if judged alone from the standpoint of those cared for, admits of little question, even if a host of economic considerations press forward and demand a hearing if not an intelligent readjustment.

It must be acknowledged that defects exist, that backsliding is not infrequent, that organization carries in its train evils of no small moment, that small malefactors may remain undisturbed for years hidden in the meshes of a large system, that laziness and incompetence may be overlooked in their minor exhibition in order that greater good may not be hampered. These we feel are but flies in the pot of ointment that honest and efficient government and highminded officials—and the State service has had a number of such—can remove, and the good work can go on.

The establishment of the Craig Colony for Epileptics marked another milepost in this State, and the

work that the State Board of Charities, the board of managers, and Dr. W. P. Spratling have done has been a credit to our institutions, and the medical profession has shown itself here, as in the State Lunacy Commission, capable, conscientious, honorable, and highly progressive. It is only the mind of small outlook that can think carping criticism of the management of our insane and our epileptics, from the economic, humanitarian, and scientific sides, as exemplified in these two enterprises.

In the State care of its idiots and imbeciles a like progressive spirit has marked the administration of the State Board of Charities, and it is with pleasure that we note the announcement that new and increased facilities for the care of the defective and epileptic are to be offered in a new colony now recommended, to be called the Haverstraw State Colony, to replace the old and cumbersome title of the Eastern New York Custodial Asylum.

The report of the commissioners, an able and thorough document, in recommending to the State the purchase of a large farm at Shiel, lying just outside of Haverstraw, for development into a colony of the type of Craig Colony, should be received and, we believe, acted upon favorably. There is need for such a colony nearer New York, where defectives, idiots, imbeciles, and epileptics may receive the kind of care which the State is abundantly able to provide, and which will reflect credit upon its administrators. The institutions already devoted to this work are well and favorably known. Craig Colony has served as a model for philanthropic enterprises far and near, and a new one along such progressive lines should receive the enthusiastic support of all physicians.

In one matter alone do we feel inclined to offer one word of suggestion, and that concerns the naming of such institutions. We should like to see the names of our philanthropists and workers for the betterment of the diseased and afflicted perpetuated in an appropriate and honorable manner. No one has worked more for these ends than Josiah P. Letchworth, for many years president of the State Board of Charities. The Letchworth State Colony, we submit, is, from this point of view, more appropriate than the name recommended; or, if as physicians, we would turn to do honor to one in our ranks who first inaugurated the movement for the training of defectives, such as are to be cared for in this new colony, the late Dr. Edward Seguin would immediately occur to our minds. Let our State institutions of this nature receive the names of our foremost citizens, and so may the community never forget those who have been their founders, and after coming generations be stimulated to the doing of good work.

## THE ROYAL SOCIETY OF MEDICINE.

The Royal Society of Medicine was formed in June, 1907, by the amalgamation of the following London medical societies: The Royal Medical and Chirurgical Society, the Pathological Society, the Epidemiological Society, the Odontological Society of Great Britain, the Obstetrical Society, the Clinical Society, the Dermatological Society, the British Gynecological Society, the Neurological Society, the British Laryngological, Rhinological and Otolological Association, the Laryngological Society, the Dermatological Society of Great Britain and Ireland, the Otolological Society of the United Kingdom, the British Electrotherapeutical Society, and the Therapeutical Society.

These societies now form sections of the new organization, the publication of which is to be known as the *Proceedings of the Royal Society of Medicine*. It is to be issued monthly from November to July. The first number has recently been received at this office. It is an octavo journal, in which the proceedings of the various sections are separately paged, evidently for future distinct binding. The articles in the initial number are chiefly clinical reports of cases and the addresses of the presidents of the various sections. There are a number of excellent illustrations.

## THE PASSING OF THE FERRY BOAT.

With the subaqueous passages already established for the conveyance of passengers to and from the borough of Manhattan and the prospect of the opening of other tubes within a short period, it seems probable that the ferry boats that have so long plied on the Hudson River and the East River will practically disappear. For some other than sentimental reasons, this state of things may not be altogether a subject for congratulation. The ferries are so accessible that they have afforded to many a poor mother a ready means of giving her sick child a reviving breath of fresh air. Of course there are longer sails that may still be taken for that purpose, and it is to be expected that some of the ferries will survive, but the reduction of their number will act as a restriction upon a cheap and readily available means of moderating infant mortality in the hot months.

## THE TEMPERATURE OF THE SUBWAY.

No New Yorker needs to be told of the oppressive heat of the subway trains in summer, a heat that persists in spite of the devices that have thus far been resorted to for its moderation, and few of them, we imagine, have yet failed to observe that

during the past winter the cars have been uncomfortably cold. It seems to us that they have been colder than in the preceding winters, colder and more pervaded by draughts, and it is the draughts especially that tend to chill a passenger. Though much less forcible, they are worse in this respect than the winds outside the tunnel, intensified as they are by our ever multiplying "sky scrapers." It is not the passengers who suffer chiefly, for their exposure is of comparatively short duration; the train hands must often sustain real injury, one would think. It is clear that better means should be taken to make the temperature of the subway comfortable at all times.

### News Items.

**Changes of Address.**—Dr. F. Ward Langstroth, to 156 West Ninety-seventh street, New York.

**A New Nurses' Registry.**—We are informed that a new registry for graduate nurses of the New York City Hospital Training School has been opened at 1185 Lexington avenue, New York.

**Wills Hospital Ophthalmic Society, Philadelphia.**—The following officers were recently elected to serve during 1908: Chairman, Dr. Samuel D. Risley; vice chairman, Dr. William Campbell Posey; secretary, Dr. Burton Chance.

**Resolutions on the Death of Dr. Probasco.**—A special meeting of the Union County, N. J., Medical Society was held in Plainfield on Thursday afternoon, February 27th, at which resolutions were adopted expressive of regret at the death of Dr. John B. Probasco.

**The Philadelphia Academy of Surgery** has elected the following officers for the year 1908: President, Dr. William J. Taylor; vice presidents, Dr. Robert G. Le Conte and Dr. G. G. Davis; secretary, Dr. John H. Gibbon; treasurer, Dr. James P. Hutchinson; and recorder, Dr. John H. Jopson.

**The Harvey Lectures.**—Professor Ross G. Harrison, of Yale University, will deliver the eighth lecture in this course at the New York Academy of Medicine on Saturday, March 7th, at 8:30 p. m. The subject of the lecture is Embryonic Transplantation and the Development of the Nervous System.

**College of Physicians of Philadelphia.**—At a meeting held on Wednesday evening, March 4th, Dr. Joel E. Goldthwait, of Boston, read a paper entitled *Our Present Understanding of the Nontuberculous (Rheumatic) Diseases of the Joints*. Dr. James C. Wilson, Dr. G. G. Davis, and Dr. Charles H. Frazier took part in the discussion.

**Nova Scotia's Children's Hospital.**—We learn from *Charities and the Commons* that a children's hospital is to be established in Halifax, N. S., in order to care for the children of the province. The sum of \$25,000 has been collected toward a building fund, and the committee will proceed at once with the plans for the new institution.

**Cincinnati Academy of Medicine.**—At the annual election, which was held on March 2d, the following officers were elected to serve for the ensuing year: President, Dr. William Gillespie; first vice president, Dr. R. B. Hall; second vice president, Dr. Stephen C. Cone; secretary, Dr. Mary Keyte Isham; treasurer, Dr. A. G. Drury; and librarian, Dr. A. I. Carson.

**Medical Society of the College of Physicians and Surgeons, Baltimore.**—At a meeting of this society, which was held on Thursday evening, February 20th, Dr. Hans Reitzke, of the Virchow Hospital, Berlin, delivered a lecture on a New Cure for Gout and Rheumatism. Dr. A. M. Forster, of the Eudowood Sanatorium, spoke on the Sanatorium Treatment of Tuberculosis, and Dr. H. S. Beck and Dr. J. J. O'Malley read papers which dealt with the

**Obstetrical Society of Philadelphia.**—At a meeting of this society, which was held on March 5th, the following papers were read: *Synctoma Malignum of the Placenta*, by Dr. E. P. Davis; *Sarcoma of the Round Ligament*, and *Fibroid Tumor of the Anterior Abdominal Wall*, by Dr. Wilmer Kumor; *Adenoma of the Cervix Associated with Fibroma of the Uterus*, by Dr. George Erety Shoemaker.

**Syracuse, N. Y., Academy of Medicine.**—A regular meeting of this academy was held on Tuesday, March 3d. Diabetes was the general topic for discussion, and papers were read as follows: *The Skin in Diabetes*, by Dr. H. C. Baum; *The Surgical Aspect of Diabetes*, by Dr. Nathan Jacobson; and *The Treatment of Diabetes*, by Dr. J. L. Heffron. The discussion was opened by Dr. F. F. Knowlton.

**Rochester, N. Y., Academy of Medicine.**—The Section in General Medicine, which includes neurology, psychiatry, materia medica, and therapeutics, held a regular meeting on Wednesday evening, March 4th. The programme included a paper on *Acute Anterior Poliomyelitis*, which was read by Dr. Robert G. Cook, and the presentation of a case of *Tuberculous Hip Disease Occurring in the Aged*, by Dr. L. A. Whitney.

**Elmira, N. Y., Academy of Medicine.**—At a meeting of this academy, which was held on Wednesday evening, March 4th, the following papers were read: *Some Points in Hygiene Well to Remember*, by Dr. H. D. Wey, of Elmira; *An Odd Case in Obstetrics*, by Dr. J. C. O'Brien, of Elmira; *Chronic Interstitial Nephritis*, by Dr. O. J. Bowman, of Horseheads; *The Diagnosis and Clinical Significance of Peritonitis*, by Dr. H. B. Smith, of Corning.

**National Congress of Mothers.**—Preliminary announcements have been sent out by this organization for a conference to be held in Washington, D. C., on March 10th to 16th. The announcement states that the members of the congress have studied the needs of children for a number of years, and at these conferences, which are annual, interesting discussions are held on the question of the best methods to adopt to bring about the highest development of the coming race.

**The Health of Pittsburgh.**—During the week ending February 15, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Smallpox, 1 case, 0 deaths; chickenpox, 9 cases, 0 deaths; typhoid fever, 41 cases, 12 deaths; scarlet fever, 25 cases, 0 deaths; diphtheria, 18 cases, 2 deaths; measles, 317 cases, 11 deaths; whooping cough, 20 cases, 2 deaths; pulmonary tuberculosis, 17 cases, 17 deaths. The total deaths for the week numbered 244, corresponding to an annual death rate of 31.46 in 1,000 of population.

**New York Academy of Medicine.**—The following papers will be read at a stated meeting of the academy, which is to be held in Hosack Hall on Thursday, March 19th, at 8:30 p. m.: *The Physiological Mechanism of Vasoconstriction and Vasodilation*, by Dr. George B. Wallace; *The Therapeutics of Vasoconstriction and Vasodilation*, by Dr. Egbert Le Fevre; *The Present Status of Experimental Arterial Disease*, by Dr. I. Adler; and *Toxic Arteritis*, with Report of a Case of Prolonged Use of Adrenalin, by Dr. Harlow Brooks and Dr. D. M. Kaplan.

**Scientific Society Meetings in Philadelphia for the Week Ending March 14, 1908.**—*Monday, March 9th*, Section in General Medicine. *College of Physicians*; *Wills Hospital Ophthalmic Society*. *Tuesday, March 10th*, Philadelphia Paediatric Society; Botanical Section, Academy of Natural Sciences. *Wednesday, March 11th*, Philadelphia County Medical Society. *Thursday, March 12th*, Pathological Society; Section Meeting, Franklin Institute. *Friday, March 13th*, Northern Medical Association; West Branch, Philadelphia County Medical Society.

**Conference on the Congestion of Population.**—At the opening session of this conference, Monday evening, March 9th, at the American Museum of Natural History, Dr. John H. Finley, president of the College of the City of New York, will preside. Among those who will make addresses are Governor Hughes, Commissioner Darlington, Commissioner Hebbard, Mrs. Vladimir G. Sinkhovitch, and His Excellency Baron Mayor des Planches, the Italian Ambassador to the United States. Reserved seats for this meeting may be obtained by addressing the committee, 105 East Twenty-second street. Three sessions will be held on Tuesday, two on Wednesday, and two on Thursday.

**The Medical Society of the Missouri Valley** will meet in Lincoln, Neb., on March 19th and 20th, on the invitation of the Lancaster County Medical Society. The address of welcome will be made by Dr. Frank Brown, mayor of Lincoln, to which Dr. R. C. McDonald, of Fremont, Neb., will respond. Dr. Charles H. Hughes, of St. Louis, will deliver the oration in medicine, and Dr. William Jepson, of Iowa, will deliver the oration in surgery. Programmes may be obtained from the secretary of the society, Dr. Charles Wood Fassett, of St. Joseph, Mo.

**Buffalo Academy of Medicine.**—The Section in Surgery held a regular meeting on Tuesday evening, March 3d. Dr. F. Whitehill Hinkel gave a demonstration of direct bronchoscopy and esophagoscopy. Dr. Marshall Clinton and Dr. Herman Hayd reported cases of echinococcus cyst of the liver. Dr. Prescott Le Breton read a paper entitled Spinal Sprain: Its Complications and Consequences, with Report of Twenty-six Cases, and Dr. Roland Meisenbach read a paper on Flat Foot. Dr. James A. Gardner is chairman of the section and Dr. Lawrence Hendee is the secretary.

**The Mortality of Minneapolis.**—We learn from the report of the Department of Health for the month of January, 1908, that during the month there were 325 deaths from all causes, corresponding to an annual death rate of 8.46 in 1,000 of population. Of the total number of deaths, 81 were from pneumonia, 33 from tuberculosis, 31 from heart diseases, 17 from Bright's disease, 9 from diarrhoea and enteritis, 5 from typhoid fever, 14 from cancer, 6 from suicide, and 13 from accidents. There were 69 deaths in public institutions. There were 464 births during the month—238 males and 226 females.

**Philadelphia County Medical Society.**—At a meeting of the Central Branch of this society, which was held on Wednesday, February 26th, the following papers were read: Ether Anesthesia, by Dr. Colin Foulkrod; Congenital Absence of the Ulna, by Dr. Francis D. Patterson; The Frequent Necessity of Multiple and Consecutive Operations for Renal Calculi, by Dr. W. Wayne Babcock. Dr. Ross H. Skillern gave a lantern slide demonstration of the Anatomy of the Accessory Sinuses of the Nose, with Especial Reference to Their Suppuration, and Dr. John J. Gilbride exhibited a specimen of hour glass contraction of the stomach.

**The Mortality of Chicago.**—According to the report of the Department of Health for the week ending February 22d, there were during the week 616 deaths from all causes, as compared with 707 for the corresponding week in 1907. The annual death rate was 14.83 in 1,000 of population. The principal causes of death were: Apoplexy, 8; Bright's disease, 47; bronchitis, 25; consumption, 63; cancer, 26; convulsions, 6; diphtheria, 10; heart diseases, 42; influenza, 23; intestinal diseases, acute, 37; measles, 3; nervous diseases, 21; pneumonia, 117; scarlet fever, 10; suicide, 8; typhoid fever, 2; violence, other than suicide, 22; whooping cough, 1; all other causes, 149.

**Opportunity for a Bacteriologist in Savannah.**—The Board of Sanitary Commissioners of Savannah, Ga., announce that an examination to fill the position of City Bacteriologist will be held simultaneously at the Research Laboratory of the Department of Health, New York; the U. S. Marine Hospital, Chicago; the Hygienic Laboratory, Washington, D. C.; the U. S. Marine Hospital Service Office, New Orleans; and the City Hall, Savannah. The term of office will be two years and the salary \$3,000 per annum. Further particulars regarding the examination are published in our advertisements pages, or may be obtained from Dr. W. F. Brunner, City Hall, Savannah, Ga.

**Association of Seaboard Air Line Railway Surgeons.** At the sixth annual meeting of this association, held last week in Tampa, Fla., February 18th, 19th, and 20th, the following officers were elected: President, Dr. J. S. Oppenheimer, of Tampa, Fla.; first vice president, Dr. J. G. Dean, of Durham, Ga.; second vice president, Dr. H. M. Wilder, of Charlotte, N. C.; third vice president, Dr. J. H. Torrey, of Richmond, Va.; treasurer, Dr. J. W. Palmer, of Atlanta, Ga.; and the executive committee is composed of Dr. James R. Rogers, of New York, N. Y.; Dr. Southgate Leigh, of Norfolk, Va.; Dr. W. C. Gault, of Camden, S. C.; Dr. J. M. Blair, of Miami, N. C.; and Dr. John W. Miller, of Carroll, S. C.

**A Dinner in Honor of Dr. Ostrander.**—The Brooklyn Medical Society gave a dinner on the evening of Saturday, February 29th, in honor of Dr. George A. Ostrander, to celebrate his completion of fifty years practice of medicine in Brooklyn. About seventy-five of the leading physicians and surgeons of Brooklyn were present, among whom were four physicians who also had completed fifty years in the profession. They were Dr. A. N. Bell, Dr. J. T. Burdick, Dr. William McCollom, and Dr. J. S. Prout. Addresses were made by each of these physicians, the subject of Dr. Ostrander's talk being the progress of medical science during the past fifty years.

**The Medical and Chirurgical Faculty of Baltimore Purchase Building Site.**—A lot, having a frontage of sixty feet on both Maryland Avenue and Cathedral street, just south of Preston street, Baltimore, has been purchased by the Medical and Chirurgical Faculty of Baltimore on which will be erected the new building which is intended to furnish quarters for a medical library, the State Board of Health, the State Board of Medical Examiners, and the local association of pharmacists, the tuberculosis commission and the State veterinary board. A building fund of \$200,000 is to be collected, of which some \$50,000 has already been pledged. The legislature will be asked to appropriate \$100,000 towards the library.

**Charitable Bequests.**—The will of Charles E. Wood provides for the establishment of a sanatorium at Atlantic City, N. J., at a cost of about \$300,000.

By the will of Elizabeth Kuntz the Wernie Orphans' Home, of Richmond, Ind., receives \$2,000. The Society to Protect Children from Cruelty, the Lutheran Home and Asylum for the Aged and Infirm, and the Home for Crippled Children are reversionary legatees.

By the will of Thomas P. Dillon the Little Sisters of the Poor, Philadelphia, receive \$500.

By the will of Cyrus Detre the Samaritan Hospital, Philadelphia, receives \$500.

By the will of Mrs. Mary E. Ives the General Hospital Society of Connecticut receives \$5,000 for the establishment of a free bed in memory of Mr. Hoadley B. Ives, and Grace Hospital, New Haven, receives \$5,000 for a free bed in memory of Mrs. Mary E. Ives.

**Infectious Diseases in Pittsburgh.**—The following cases of transmissible diseases have been reported to the Bureau of Health of Pittsburgh:

Week ending,	Jan. 4	Jan. 11	Jan. 18	Jan. 25	Feb. 1	Feb. 8
	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.
Chickenpox	12	3	12	3	14	3
Diphtheria	20	22	11	24	11	20
Scarlet fever	10	10	10	4	20	1
Dysentery	2	2	2	3	2	1
Typhoid fever	2	2	2	3	2	4
Whooping cough	1	1	1	1	1	1
Measles	1	1	1	1	1	1
Smallpox	1	1	1	1	1	1
Infantile paralysis	1	1	1	1	1	1
Polio	1	1	1	1	1	1
Unlabeled	1	1	1	1	1	1
Total deaths	58	68	50	64	54	64
Annual death rate in 1,000 of population	12.8	14.8	14.8	14.8	14.8	14.8
Estimated population	1,000,000	1,000,000	1,000,000	1,000,000	1,000,000	1,000,000

**The Health of Philadelphia.** During the week ending February 8, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Typhoid fever, 114 cases, 18 deaths; scarlet fever, 55 cases, 4 deaths; chickenpox, 44 cases, 0 deaths; diphtheria, 88 cases, 11 deaths; whooping cough, 1 case, 0 deaths; measles, 125 cases, 3 deaths; whooping cough, 33 cases, 5 deaths; pneumonia, 117 cases, 22 deaths; influenza, 23 cases, 30 deaths; typhoid fever, 2 cases, 1 death; tetanus, 2 cases, 1 death; puerperal fever, 2 cases, 4 deaths; smallpox, 1 case, 0 deaths; scarlet fever, 1 case, 0 deaths.

The following deaths were reported during the week ending February 8, 1908: Typhoid fever, 18 deaths; scarlet fever, 4 deaths; chickenpox, 0 deaths; diphtheria, 11 deaths; whooping cough, 1 death; measles, 3 deaths; whooping cough, 3 deaths; pneumonia, 22 deaths; influenza, 3 deaths; typhoid fever, 1 death; tetanus, 1 death; puerperal fever, 4 deaths; smallpox, 0 deaths; scarlet fever, 0 deaths; chickenpox, 0 deaths; diphtheria, 0 deaths; whooping cough, 0 deaths; measles, 0 deaths; whooping cough, 0 deaths; pneumonia, 0 deaths; influenza, 0 deaths; typhoid fever, 0 deaths; tetanus, 0 deaths; puerperal fever, 0 deaths; smallpox, 0 deaths; scarlet fever, 0 deaths; chickenpox, 0 deaths; diphtheria, 0 deaths; whooping cough, 0 deaths; measles, 0 deaths; whooping cough, 0 deaths; pneumonia, 0 deaths; influenza, 0 deaths; typhoid fever, 0 deaths; tetanus, 0 deaths; puerperal fever, 0 deaths; smallpox, 0 deaths; scarlet fever, 0 deaths; chickenpox, 0 deaths; diphtheria, 0 deaths; whooping cough, 0 deaths; measles, 0 deaths; whooping cough, 0 deaths; pneumonia, 0 deaths; influenza, 0 deaths; typhoid fever, 0 deaths; tetanus, 0 deaths; puerperal fever, 0 deaths; smallpox, 0 deaths; scarlet fever, 0 deaths; chickenpox, 0 deaths; diphtheria, 0 deaths; whooping cough, 0 deaths; measles, 0 deaths; whooping cough, 0 deaths; pneumonia, 0 deaths; influenza, 0 deaths; typhoid fever, 0 deaths; tetanus, 0 deaths; puerperal fever, 0 deaths; smallpox, 0 deaths; scarlet fever, 0 deaths; chickenpox, 0 deaths; diphtheria, 0 deaths; whooping cough, 0 deaths; measles, 0 deaths; whooping cough, 0 deaths; pneumonia, 0 deaths; influenza, 0 deaths; typhoid fever, 0 deaths; tetanus, 0 deaths; puerperal fever, 0 deaths; smallpox, 0 deaths; scarlet fever, 0 deaths; chickenpox, 0 deaths; diphtheria, 0 deaths; whooping cough, 0 deaths; measles, 0 deaths; whooping cough, 0 deaths; pneumonia, 0 deaths; influenza, 0 deaths; typhoid fever, 0 deaths; tetanus, 0 deaths; puerperal fever, 0 deaths; smallpox, 0 deaths; scarlet fever, 0 deaths; chickenpox, 0 deaths; diphtheria, 0 deaths; whooping cough, 0 deaths; measles, 0 deaths; whooping cough, 0 deaths; pneumonia, 0 deaths; influenza, 0 deaths; typhoid fever, 0 deaths; tetanus, 0 deaths; puerperal fever, 0 deaths; smallpox, 0 deaths; scarlet fever, 0 deaths; chickenpox, 0 deaths; diphtheria, 0 deaths; whooping cough, 0 deaths; measles, 0 deaths; whooping cough, 0 deaths; pneumonia, 0 deaths; influenza, 0 deaths; typhoid fever, 0 deaths; tetanus, 0 deaths; puerperal fever, 0 deaths; smallpox, 0 deaths; scarlet fever, 0 deaths; chickenpox, 0 deaths; diphtheria, 0 deaths; whooping cough, 0 deaths; measles, 0 deaths; whooping cough, 0 deaths; pneumonia, 0 deaths; influenza, 0 deaths; typhoid fever, 0 deaths; tetanus, 0 deaths; puerperal fever, 0 deaths; smallpox, 0 deaths; scarlet fever, 0 deaths; chickenpox, 0 deaths; diphtheria, 0 deaths; whooping cough, 0 deaths; measles, 0 deaths; whooping cough, 0 deaths; pneumonia, 0 deaths; influenza, 0 deaths; typhoid fever, 0 deaths; tetanus, 0 deaths; puerperal fever, 0 deaths; smallpox, 0 deaths; scarlet fever, 0 deaths; chickenpox, 0 deaths; diphtheria, 0 deaths; whooping cough, 0 deaths; measles, 0 deaths; whooping cough, 0 deaths; pneumonia, 0 deaths; influenza, 0 deaths; typhoid fever, 0 deaths; tetanus, 0 deaths; puerperal fever, 0 deaths; smallpox, 0 deaths; scarlet fever, 0 deaths; chickenpox, 0 deaths; diphtheria, 0 deaths; whooping cough, 0 deaths; measles, 0 deaths; whooping cough, 0 deaths; pneumonia, 0 deaths; influenza, 0 deaths; typhoid fever, 0 deaths; tetanus, 0 deaths; puerperal fever, 0 deaths; smallpox, 0 deaths; scarlet fever, 0 deaths; chickenpox, 0 deaths; ### Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Department of Health for the following statement of new cases and deaths reported for the two weeks ending February 29, 1908:

	—February 22—		—February 29—	
	Cases.	Deaths.	Cases.	Deaths.
Tuberculosis pulmonalis	388	241	451	234
Diphtheria	371	45	373	44
Measles	1,252	20	1,554	39
Scarlet fever	707	39	924	39
Smallpox	—	—	—	—
Varicella	133	—	186	—
Typhoid fever	33	4	45	9
Whooping cough	9	1	20	1
Cerebrospinal meningitis	13	9	16	8
Totals	2,993	325	3,593	344

**Personal.**—Dr. Walter E. Whitney, of Waterville, Me., and Dr. Frank J. Vankirk, of Bellingham, Wash., are registered at the Philadelphia Polyclinic and College for Graduates in Medicine.

Dr. Jacob Frank, of Chicago, has received from Count Matsukato, president of the Red Cross Society of Japan, a medal made from weapons actually used on the battlefield, in recognition of the service rendered by him during the Russo-Japanese War.

Dr. Mortimer J. Lampson has been appointed superintendent of the Jersey City Hospital.

We learn from the *Canadian Journal of Medicine and Surgery* that Dr. George Elliott, of Toronto, has been appointed provincial medical examiner for the Royal Arcanum in Ontario.

Dr. Charles D. Aaron, of Detroit, has been appointed a member of the Committee of One Hundred on National Health.

Dr. William H. Taylor, of Cincinnati, was tendered a dinner at the Queen City Club on the evening of March 2d, in honor of the fiftieth anniversary of his graduation in medicine.

Dr. Elizabeth Blackwell, of Hastings, England, who is the first woman to take a medical degree, was eighty-six years old on February 3d.

**The Grand Legion of the Red Cross** is the name given to a trained volunteer army of first aid, which is being organized by the American National Red Cross. The Grand Legion is made up of four or more legions, each legion has four relief columns, each column four detachments, and each detachment four squads. The first relief columns were formally organized on January 22, 1908, in Brooklyn, under the direction of Dr. Glentworth Butler, who was assisted by Major Charles Lynch, of the Medical Department of the U. S. Army, who has been specially detailed by the Surgeon General to aid in the work. The members of the Legion will be taught to give first aid under all conditions, and will be prepared to serve as a body in time of need. They will not be obliged to serve in the Army hospital corps in time of war, but may do so if they wish. The chief work of the Legion will be, both directly and indirectly, a crusade against preventable accidents, and it is estimated that about two thirds of the 10,000,000 accidents a year in the United States are preventable. The Grand Legion will not be composed of men alone; each relief column will eventually have attached to it a relief corps of women trained in first aid and home nursing. Further information concerning this work may be obtained at the New York State Branch of the American National Red Cross, 500 Fifth avenue, New York.

**Philadelphia Bureau of Health Statistics.**—During the month of December, 1907, in the Division of Medical Inspection 3,952 inspections were made, excluding schools; 715 fumigations were ordered; 64 cases were referred for special diagnosis; 4,624 visits were made to schools; 556 children were excluded from school; 418 cultures were taken; 132 injections of antitoxine were given; and 208 persons were vaccinated. In the Division of Vital Statistics 2,143 deaths, 2,600 births, and 196 marriages were reported. In the Division of Milk Inspection 8,304 inspections were made of 190,172 quarts of milk, of which 984 quarts were condemned. Thirteen specimens were examined chemically and 989 microscopically. In the Division of Meat and Cattle Inspection 3,897 inspections were made; 286 were found unsanitary; 207 condemnations were ordered. Fifty-nine post mortem examinations were made,

of which 8 were condemned. In the Division of Disinfection 271 fumigations were done for scarlet fever, 501 for diphtheria, 91 for typhoid fever, 173 for tuberculosis, 290 for miscellaneous diseases, and 36 schools were fumigated. In the Bacteriological Laboratory 1,714 cultures were examined for the bacillus diphtheriae; 416 specimens of blood were examined for the serum diagnosis of typhoid fever; 973 specimens of milk were examined; 156 specimens of sputum were examined; 3 disinfection tests were made; and 3,716,400 units of antitoxine were distributed. In the Chemical Laboratory 119 analyses were made.

### Society Meetings for the Coming Week:

**MONDAY, March 9th.**—New York Academy of Medicine (Section in Neurology and Psychiatry); Society of Medical Jurisprudence, New York; New York Ophthalmological Society; Corning, N. Y., Medical Association; Waterbury, Conn., Medical Association.

**TUESDAY, March 10th.**—New York Academy of Medicine (Section in Public Health); New York Obstetrical Society; Newburgh Bay, N. Y.; Medical Society; Medical Society of the County of Schenectady, N. Y.; Medical Society of the County of Rensselaer, N. Y.; Buffalo Academy of Medicine (Section in Medicine); Practitioners' Club of Jersey City.

**WEDNESDAY, March 11th.**—New York Pathological Society; New York Surgical Society; Medical Society of the Borough of the Bronx, New York; Alumni Association of the City Hospital, New York; Brooklyn Medical and Pharmaceutical Association; Medical Society of the County of Richmond, N. Y.

**THURSDAY, March 12th.**—New York Academy of Medicine (Section in Pediatrics); Brooklyn Pathological Society; Blackwell Medical Society of Rochester, N. Y.; Jenkins Medical Association, Yonkers, N. Y.

**FRIDAY, March 13th.**—New York Academy of Medicine (Section in Otolaryngology); New York Society of Dermatology and Genitourinary Surgery; Eastern Medical Society of the City of New York; Saratoga Springs, N. Y., Medical Society.

**SATURDAY, March 14th.**—Therapeutic Club, New York.

**Meetings of Sections of the New York Academy of Medicine.**—The Section in Pediatrics will meet on Thursday evening, March 12th, at 8:15 o'clock. The meeting will be devoted to the presentation of patients and a discussion by members of the section.

The Section in Otolaryngology will hold a meeting on Friday evening, March 13th, at 8:15 o'clock. Dr. G. H. Cocks will present a patient showing recurrent keloid of the scalp and lobule of the ear, and Dr. Frederick Whiting will read a paper entitled *The Toxæmia of Latent Erysipelas in Its Relation to Otitic Serous Meningitis*.

A meeting of the Section in Public Health will be held on Tuesday evening, March 10th, at 8:15 o'clock. Dr. Simon Baruch will read a paper on *Public Baths, Their Need and Usefulness*, and a paper on *Public Comfort Stations* will be read by Frederick L. Lord, City Engineer, Hartford, Conn. The discussion will be opened by Dr. S. A. Knopf.

A meeting of the Section in Surgery was held on Friday evening, March 6th, which was devoted to a general discussion on aneurysm. Papers on the subject were read as follows: *The Treatment of Popliteal Aneurysm by the Reconstructive Method*, by Dr. J. F. Binnie, of Kansas City; *Personal Experience with the Modern Treatment of Aneurysm*, by Dr. Robert Abbe; *A Report of Two Cases of Aneurysm*, by Dr. Joseph A. Blake; *The Serous Coat of Blood Vessels Compared with the Peritonæum*, by Dr. Robert T. Morris.

On Monday evening, March 9th, the Section in Neurology and Psychiatry will hold a meeting, for which the following programme has been arranged: Dr. William B. Pritchard will present two patients showing progressive muscular dystrophy; Dr. John Hartwell will report two cases of suture of the ulnar and median nerves, and a general discussion on the subject will follow; Dr. Charles N. Dowd will report cases of tendon transfer for paralytic deformities of the foot; Dr. John A. Bodine will read a paper entitled *Injection of Alcohol for the Cure of Trigeminal Neuralgia*; and Dr. R. H. Dawbarn will read a paper entitled *The Shortening of All Sensory Nerves an Essential Step in All Amputations*.

## Pith of Current Literature.

### THE BOSTON MEDICAL AND SURGICAL JOURNAL.

February 27, 1908.

1. The Bennett Fracture of the First Metacarpal Bone, Diagnosis and Treatment. By SAMUEL ROBINSON.
2. The Treatment of Trophic Nerve Lesions: A Study Based on a Case of Mal Perforans of Ischemic Paralysis, and of Erythromelalgia, By WILLIAM C. QUINBY.
3. Pulmonary Embolus Following Operative Interferences, By CHARLES GREENE CUMSTON.
4. Psychology in Medicine, By ARTHUR H. BING.

1. **Bennett Fracture of the First Metacarpal Bone.**—Robinson remarks that the first and fifth metacarpal bones are most frequently fractured. Sixty-four per cent. of fractures of the first metacarpal are of a less obstinate transverse type. Twenty-eight per cent. are oblique fractures into the joint, with or without subluxation of the metacarpal (Bennett type). Certain forms of the Bennett lesion are difficult of treatment and render all injuries to the base of the thumb worthy of a skiagraph for their early detection. For transverse fractures without much deformity any simple immobilization splint is sufficient to produce union. Such methods of fixation have also proved adequate in certain oblique fractures into the joint where subluxation had not already occurred, and owing to ligamentous support remained in position until maintained by bony or cartilaginous union of the fragment to the shaft. For the Bennett fracture with fracture and subluxation, different methods have been employed. Our author regards the method of Miles, Struthers, and Bennett inadequate. He describes his method as follows: Two narrow strips of adhesive plaster are first applied to the lateral surfaces of the thumb with free ends about six inches long. These strips are held in position by circular turns of the adhesive. In preparation for the spica, the thumb, metacarpal region, and wrist are bandaged with cotton sheet wadding. To provide space between the thumb and plaster spica in which the thumb may be later extended, two narrow pieces of splint wood, such as are used as tongue depressors, are laid laterally against the cotton. They should extend an inch beyond the tip of the thumb in order that the circular turns of the plaster spica may continue the extension cylinder beyond the tip. With the thumb well abducted a plaster of Paris bandage, cut to width of two inches, is then firmly applied as spica from the wrist. As the plaster hardens, extension should be maintained with traction on the adhesive plaster strips. At the same time pressure should be applied over the proximal end of the subluxated fragment. A second layer of plaster bandage should then be applied for added support and for the incorporation, if so desired, of two buckles. The splint wood is then withdrawn through open end of cylinder. Traction is exerted on the adhesive extension strips which are turned backward over the now firm edge of the extension trough, and held in position by the buckles, or, if the latter are not available, a circular turn of adhesive around the hand outside the spica will answer the purpose. The following day the pull on the extension strips should be increased to make up

for stretch in material, for yielding in the grip of the strips on the thumb and for muscle relaxation. This should be repeated every two days for at least a week. Four or even five weeks is none too long a time for the maintenance of this apparatus. At the end of three weeks to make up for reduced swelling the spica may be carefully removed and a new plaster spica restored with the same moulding over the seat of fracture but without the extension apparatus.

#### 2. The Treatment of Trophic Nerve Lesions.

—Quinby remarks that the so called trophic nerve lesions of the skin, bones, and joints are due to a break in the neurovascular mechanism of the part involved. This break may be situated centrally or on the neural side, or on the vascular side. Hence, rational treatment of such conditions will be directed toward modification of the blood supply; or the nerve function of the part. For modification of the blood supply, we have active and passive hyperæmia increasing it, and positive pressure by bandaging, pneumatic cabinet, or the immersion in mercury, decreasing it, while for modification of the nerve function, we have nerve stretching, neurolysis and nerve disassociation, and electricity. Nerve stretching is probably to be condemned, similar results being obtainable by the simpler passive hyperæmia.

### THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

8. The Heart's Action Preceding an Epileptic Seizure, By J. F. MUNSON.
9. Sterile Hands Secured by Abstinence from Infection: the Essential Factor in Successful Surgery, By J. H. CARSTENS.
10. Tuberculosis and the Medical Schools, By DAVID R. LYMAN.

#### 2. Some Studies of the Endogenous Uric Acid Moiety in Pathological Conditions.

—Peck and Thompson summarize their investigation as follows: A certain number of patients showing nervous and other symptoms are suffering from disturbances of metabolism of such nature as to lead to an abnormally low output of endogenous urinary purins. Just what these metabolic abnormalities are the authors can not at present state, because of ignorance of the exact physiological processes concerned in the formation of the endogenous moiety, but that they are, in a measure at least, responsible for some of the symptoms is shown by the relief of these same symptoms on increasing the elimination of the urinary purins. The best method of bringing about this result is not by trying to dissolve the uric acid, as has been our endeavor in the past, but to increase the activity of the metabolic processes. This latter

accomplishment is best attained by exposing the naked body to the direct rays of incandescent electric lights.

**5. The Relations of the Diaphragm as Revealed by the Röntgen Ray.**—Lange remarks that the diaphragm functionates in an analogous manner to the other muscles of the body. Its excursion is greatest when its points of origin and insertion are most widely separated, and it acts more forcibly against resistance than when acting unopposed. The practical application of the study of the diaphragm by means of the x ray will be possible perhaps only in the larger hospitals where the Röntgen equipment is complete. But its importance as a routine method of examination is not an inconsiderable one. In feeble patients where auscultation is difficult because the breathing is weak and suppressed and percussion is unsatisfactory because of the inadvisability of turning and lifting the patient, this method is especially valuable, for the examination may be conducted in the recumbent position without in any way disturbing the patient. The high convex position of the diaphragm is dependent on the combined action of two forces. When either fails the dome drops downward. One factor is the elasticity of the lungs, maintaining a constant suction in the pleural sac. The other is the pressure of the abdominal contents. This abdominal pressure is of a hydrostatic nature, in that it is equally distributed over the entire lower surface of the diaphragm. This pressure is due, in the upright posture, to the compression exerted by the abdominal musculature on the abdominal viscera, while in the recumbent position the abdominal contents influence the diaphragm by gravitating against it. That these forces support the diaphragm is shown in phrenic paralysis where the diaphragm stands at a high level and rises during inspiration and sinks during expiration, although its own tonus is lost. That there is an upward suction and an upward pressure on the diaphragm is shown in phrenic hernia where the stomach enters the thorax through a rent in the diaphragm. When the elastic suction of the lung is removed, as in emphysema, the diaphragm stands low. Variations in the pressure from below are shown by variations in the phrenic level, depending on whether the individual is lying, standing, or sitting. The phrenic level is highest when the patient is recumbent, in which position the abdominal contents, acted on by gravity, push against the diaphragm. When standing the diaphragm is slightly lower than when lying down. The force here is the rigidity of the abdominal walls exerting pressure on the viscera, which force is partly counteracted by gravity pulling the abdominal contents away from the diaphragm. In the sitting position the diaphragm is lowest, for in this attitude the abdominal musculature is partly relaxed, and the force of gravity acting on the abdominal contents less opposed sucks the diaphragm downward. But notwithstanding this pressure, its excursion is greater than the opposite unopposed half. This upper half, furthermore, acts very peculiarly. It stands comparatively low, and instead of sweeping up and down with its fellow of the lower side it remains almost motionless, swinging in a sort of pendulum fashion about a point which runs through its middle point.

In other words, its excursion is decreased because its points of origin and insertion are approximated and because its action is unopposed.

**6. The Choice of a Vasodilator.**—Cook says that sodium nitrate is the best vasodilator; it has the most enduring effects; is most stable and dependable; and gives rise to fewest unpleasant symptoms. Vasodilatation may be indicated with low or normal tension, i. e., all uncontrollable hæmorrhage, either during operative manipulation, typhoid ulceration, gastric ulcer, pulmonary phthisis, other internal hæmorrhage uncontrollable by surgical methods, aneurysm, thrombus, etc. High tension is abnormal, and is either the accompaniment of organic disease, or else presages its onset; in either case it demands treatment; first, by general hygienic measures; second, when necessary, by venesection or vasodilatation with drugs—preferably sodium nitrate.

**8. The Heart's Action Preceding an Epileptic Seizure.**—Munson has made observations on the heart's action preceding an epileptic seizure. Looking over the cases reported it will be seen that the condition common to all but one was an acceleration of the pulse preceding the seizure and lasting through the onset stage to the moment of the first recorded convulsion. This acceleration was never great. The absence of a time marker prevented exact statements, but the increases seemed to be in the several cases, from eight to nine, or from twelve to fifteen or seventeen beats. In all the cases the pulse was entirely regular. For this group of cases one can conclude definitely: Cardiac arrest does not occur; except for slight acceleration, and in one case slight slowing, the heart does not take part in the convulsion.

#### MEDICAL RECORD

February 29, 1908.

1. Chronic Sigmoiditis, By HEINRICH STERN.
2. Cardiac Hydrothorax. Report of a Case Aspirated 311 Times, By W. TRAVIS GIBB.
3. Acute Bulbar Paralysis, with an Unusual Symptom, By ALFRED GORDON.
4. Significant Features of Middle Ear Suppurations in Infancy and Childhood, By S. J. KOPETZKY.
5. Dangers Attending Operative Intervention in Gonorrhœal Salpingitis. Report of a Case, By J. S. PRICE.
6. Ether Anæsthesia, By DEAN LOREE.

**1. Chronic Sigmoiditis.**—Stern reports eight cases of chronic sigmoiditis, forming about the sixth part of all the cases of that affection which have come under his observation. Naturally, extent and intensity of the inflammatory processes were of manifold degree in the various instances. That an inflammatory condition may be limited to the sigmoid flexure there is no question. That such an inflammatory condition may be idiopathic, at least in a proportion of cases, we have to assume on logical grounds. However, we will not be far out of the way when we maintain that a goodly number of the pertaining instances are deuteropathic in character; that they are, in other words, the consequence of a preexisting condition. The direct local condition predisposing to inflammation of the sigmoidal mucosa is habitual obstipation and long continued drug catharsis, the more mediate cause acting as predisponent for sigmoiditis being an adequate or perverse nerve impulse in the descending and especially in

the sigmoidal segments of the colon. In every instance of chronic sigmoiditis which came to his notice, there prevailed obstipation or a tendency thereto, and the characteristic lethargy of the large intestine, which is directly attributable to the customary ingestion of purgatives. Stagnation of the feces occurs mostly in the lower portion of the descending colon and in the sigmoid flexure, the peculiar anatomy of which virtually invites the retention of feculent material. Inflammatory processes of the colonic and sigmoidal mucosa may thus be set up readily, to some extent, by mechanical injury on the part of the accumulated excrementitious substances, to some extent by chemical irritation of the products of secondary fermentation evolved from the impacted feces. Intestinal spasm, atony, or paresis, by giving occasion to obstipation, may be the more remote causes of chronic inflammatory processes of the sigmoid flexure. The great majority of all intestinal affections which are due to insufficient or perverse innervation arise in the sigmoid. An initial intestinal spasm is almost in every instance confined to the sigmoid; intestinal atony or paresis, as a rule, starts in the sigmoid; seventy per cent. of all cases of volvulus—due primarily in almost every instance to fecal impaction, and induced forced peristalsis, that is, perverse innervation—occur in the sigmoid flexure. Chronic sigmoiditis may be associated with numerous concomitants and complications. Its occurrence, in fact, favors the production of other, especially functional, disturbances of the alimentary canal. Functional disorders of the cæcum, for instance, are often due to a chronic pathological condition of the sigmoid. The synchronous occurrence of cæcal derangement and the syndrome of chronic sigmoiditis often present the clinical picture of chronic appendicitis. Again, we know that in the aetiology of appendicitis itself, chronic obstipation (and consequently sigmoidal disease) plays an important rôle. Furthermore, perisigmoiditis may be due to the same cause which gives occasion to endosigmoiditis, or it may be the direct consequence of the latter, and inflammatory processes in other parts of the peritonæum may be engendered by chronic sigmoiditis or its most frequent immediate precursor, obstipation.

4. **Significant Features of Middle Ear Suppurations in Infancy and Childhood.**—Kopetzky finds the significant features of middle ear suppuration in infancy and childhood to lie in the existence of the purulence without perforation; in the presence of a discharge from the Eustachian tube to the pharynx; in the exhibition of temperature, early facial paralysis and marked disturbance of stomach and bowel; in the advent of periosteal abscess; in the rapid progress of destructive processes in the petrous lobe; in the tendency to extensive ossifications; in the possibility of early primary bulbar thrombosis; in the existence of the characteristic of otitic pyæmia, and in the relatively serious sequelæ of certain forms of ear disease in the child, who is exposed to the danger of deafness in the loss of a special sense so intimately related to the functions of speech.

6. **Ether Anæsthesia.** Laro reports that in the past the more liberal use of ether once administered has been deemed sufficient precaution without at-

tempting a study of the possibilities of the latter. The profession seems to be awakening to the fact that proper etherization calls for experience and that, within certain limits, a maximum dosage must be established. Much is being written concerning the different forms of apparatus, and this or that method calls for much or little commendation, whereas the true test is the anæsthetist himself, and that mode of administration is superior which in his hands permits him to employ the smallest quantities of ether. The drop method has done more for ether in general than any one thing since its discovery. Averages of five ounces of ether per hour may be obtained with the Allis inhaler slightly modified. Nitrous oxide gas preceding ether is unnecessary; the former is valuable in selected cases, not only for minor but, if properly given, may be prolonged for major operations. Primary anæsthesia with ether is valuable in many short operations, viz.: extraction of teeth, incision of abscesses, urethral dilations, etc. The average amount of ether required per hour is four ounces, when complete unconsciousness must be continuous. The longer the operation is prolonged the less ether is necessary for any given period of time. The longest period of ether anæsthesia that has come under his observation was five and one half hours, in the case of a radical mastoid operation with exploration of the brain and ligation of the left common carotid; the amount of ether used was fourteen ounces. Proficiency in future will require the minimum amount of ether instead of the promiscuous "soaking" of the past. When this is made obligatory, vomiting is the exception, not the rule; the excitement stage is wanting; the intense irritation of bronchial mucous membrane is never experienced, and the capillary circulation is as good, sometimes better, than before administration.

#### BRITISH MEDICAL JOURNAL

February 15, 1908

1. Chorea of Aggravated Type with Certain Unusual Phenomena, By R. W. PHILIP.
2. Chronic Bronchitis, By A. G. AULD.
3. Surgical Aspects of Subphrenic Abscess, By H. L. BARNARD.
4. Preliminary Notes on the Incidence of an Acute Tuberculous Fever in India Which Has Been Confounded with Continuous and Remittent Fevers, By J. R. KILLICK AND P. R. BANERJEE.
5. On the Spread and Prevention of Tuberculous Disease in Pondoland, South Africa, By J. G. MILLAR.
6. The Prevention of Tuberculosis: A Suggestion, By A. R. GUNN.
7. The Treatment of Epidemic Cerebrospinal Fever by Intraspinal Injections of Flexner and Jobling's Antimeningitis Serum, By A. G. ROHR.

1. **Chorea.**—Philip reports a case of chorea of an aggravated type occurring in a youth aged eighteen years, and which ended fatally. Among the unusual phenomena observed was the condition of hipso, i. e., the point of the toes was abnormally rigid and contracted in extraordinarily rapid fashion. The age of the patient was unusual, in that the great majority of cases occur between the ages of five and fifteen years. The family history in cases of chorea often traces a hereditary tendency to rheumatism to a remote generation. The ultimate causation of chorea is still a mystery. The serious character of the symptoms and their extreme violence in some

cases are much in favor of the disease being due to irritation. In particular, various toxins are admitted as irritants, especially that associated with rheumatism. The disease follows other infective conditions besides rheumatism—scarlet fever, measles, small pox, diphtheria, typhoid fever, and many other conditions. Shock, fright, etc., are probably merely predisposing influences which determine the direction in which the effects of intoxication may show themselves. Up to the present there is no certain, constant post mortem appearance which can be predicated as the anatomical basis of the disease. The prognosis is grave in the severer types. The patient should be on a water bed, and his larger joints wrapped in cotton wool. Of drugs the most serviceable are the bromides and chloral.

2. **Chronic Bronchitis.**—Auld discusses the causation and treatment of chronic bronchitis. Three drugs have a specific action on the epithelial and glandular tissues; they are potassium iodide, balsam of Peru, and turpentine. Of these the balsam of Peru is the most efficacious and the most generally applicable. When the expectoration is already free, begin at once with the balsam in doses of ten to twenty minims, given disguised in an emulsion. If the expectoration is scanty and difficult to expel, begin with five to eight grains of potassium iodide, and, having obtained a free expectoration, follow up with the balsam of Peru.

4. **Acute Tuberculous Fever.**—Roberts and Bhandarkar call attention to the existence of an acute fever, due to the tubercle bacillus, and which is often confounded with typhoid and malarial fever. The fever is of a remittent or intermittent type, lasting from a week to four weeks; the liver is often enlarged, the spleen not so. Vomiting and nausea are marked, but not continuous. The most distinguishing feature is pain and tenderness in the epigastrium, on which stress is laid in diagnosis. Some cases have acute exacerbations of pain, others only tenderness, which, if it is associated with hepatic enlargement, makes the diagnosis from liver abscess very difficult; but the detection of tubercle bacilli in the urine clears up all doubt. The mind is clear, generally remarkably so. The tongue is furred, but not coated as in typhoid fever. This fever is completely recoverable from, but it marks the launching of the patient on a tuberculous career—the beginning of a long period of ill health of an indefinite kind. This general malaise is not continuous. Another set of cases develop obvious tuberculosis—tubercle of the lungs, kidneys, etc. The initial acute tuberculous fever has been by that time completely forgotten. In this fever the abdominal symptoms point to probable invasion through the alimentary canal. It is not to be confounded with tuberculous peritonitis. The mortality is low, and the condition does not drift into acute miliary tuberculosis. The direct evidence is supplied by the detection of the tubercle bacillus in the urine. The technique is that given in the books; attention is called to the importance of a good centrifuge, the washing of the deposit in distilled water once or twice to insure fixation, and the use of egg albumin to facilitate this. The Ziehl carbol fuchsin method of staining was the one used. The writers are convinced that there exists a tuberculous cachexia, not only as the

sequela of acute tuberculous fever, but coming on gradually, and manifesting itself by indefinite malaise. Its detection depends on the examination for tubercle bacilli in the urine. This stage is probably the precursor of an evident tuberculous disease, such as affections of the lungs, kidneys, bones, or abdominal organs. This cachexia exists along with a low opsonic index, and it is important to raise this to effect a cure.

6. **Prevention of Tuberculosis.**—Gunn suggests that the problem of tubercle free milk can be solved by taking those members of the herd of cattle which are immune to tuberculosis, and breeding from them and them alone.

7. **Serum Treatment of Cerebrospinal Meningitis.**—Robb reports a series of thirty cases of cerebrospinal meningitis treated with Flexner and Jobling's antimeningitis serum. Eight patients died, a mortality of 26.6 per cent. Of thirty-four cases treated at the same time without the serum, twenty-nine patients died, a mortality of 85.2 per cent. The general mortality in Belfast of the disease was 72.3 per cent. These results are encouraging. Three cases were of the fulminant type, four of the ordinary type, and one was already "chronic."

By F. A. SOUTHAM.

2. **Tuberculin Treatment.**—Raw holds that human and bovine tubercle bacilli are divisible into two distinct types of a common species, (1) *typus humanus*; and (2) *typus bovinus*. Man, from feeding for centuries upon cattle products—milk, cheese, etc.—has become tolerant to the bovine bacilli. Tubercle bacilli of the *typus humanus* produce phthisis pulmonalis, ulceration of the intestines, and tuberculous laryngitis; and tubercle bacilli of the *typus bovinus* produce tuberculous peritonitis, tuberculosis of the lymphatic glands, tuberculous joints, meningitis (probably), and lupus. Acute miliary tuberculosis is probably also of bovine origin. In the author's experience, Koch's tuberculin R. has little or no healing effect in phthisis pulmonalis. He has therefore prepared from bovine sources a special tuberculin for the treatment of pulmonary tuberculosis, the results from which have been most excellent. Working on corresponding lines, he has treated over seventy cases of surgical or bovine tuberculosis with Koch's tuberculin R. The results

have been beyond anticipation: enlarged glands, joints, and lupus have been immensely improved, while discharging sinuses have cleared up, and the symptoms of meningitis have disappeared (in two cases).

3. **Acute Poliomyelitis.**—Pasteur, Foulerton, and MacCormac report that after having identified a micrococcus in the spinal fluid withdrawn during life from a boy with symptoms of acute poliomyelitis, they succeeded in producing an ascending motor paralysis in a rabbit, after a prolonged period of incubation, by inoculating this fluid into the subdural space. On the death of the rabbit a micrococcus could be demonstrated in the cerebrospinal fluid similar to that seen in the fluid from the human case; and by similarly inoculating another rabbit with an emulsion of cerebrospinal substance and fluid from the first experimental animal they again succeeded in producing a motor paralysis again associated with the presence of the micrococcus in the spinal fluid. The evidence is bacteriologically incomplete, however, as it was not possible to cultivate the organism on artificial media. The writers hold that the investigations of Geirsvold and others have established beyond question the existence of a specific infective disease of which acute poliomyelitis is a frequent and prominent, but not essential, feature. This specific disease has apparently no clearly distinctive primary features to enable one to distinguish it by its clinical symptoms from many other febrile conditions of probably infective origin. And so while the serious complications of acute poliomyelitis when it has occurred has been at once recognized, the primary disease has not been distinguished hitherto, but has in fact usually been altogether overlooked. But there is not sufficient reason for assuming that acute poliomyelitis is always a result of this particular diplococcal infection. The symptoms by which acute poliomyelitis is recognized are the consequences of a constitutional alteration of certain cells of the central nervous system, which causes an impairment of their functional efficiency. It is probable that these cell changes may be caused also by the toxins produced in other infective processes.

4. **Therapeutics of Normal Serum.**—Hort has treated with the most encouraging results a number of morbid conditions by the administration of normal blood serum. Among the diseases treated in this way are gastric and duodenal ulcer, with and without hemorrhage, chlorosis, and other forms of anemia, hæmophilia, purpura hæmorrhagica, tuberculous peritonitis, hæmoptysis, ulcerations of all kinds, pulmonary oedema, pneumonia, etc. Whatever value normal serum therapy may prove to have, it does not seem obviously connected with supplying fibrin ferment. It is conceivable that the administration of normal serum may effect the production of autoimmunity, or in some unknown way correct a disturbance of the regulating mechanism. It is not impossible that in all the conditions mentioned there is a common basis of auto-intoxication characterized by destruction of epithelial, endothelial, leucocytes, or other cells, which autolysis can be inhibited by normal serum.

7. **"Early" Operation in Appendicitis.**—South-

pendicitis. The temperature and pulse rate bear no constant relation to the severity of the attack. A rapid pulse is also suggestive of serious mischief and points to a probable termination in suppuration. The same applies to a high temperature. A subnormal temperature, especially if the fall has been sudden, often indicates perforation. A high temperature and a slow pulse, or *vice versa*, are always unfavorable, the same being true of an initial rigor, urgent vomiting, acute pain, and painful rigidity of the abdominal wall. Another important early symptom, pointing to the onset or the presence of the destructive form of appendicitis, is the absence of abdominal respiration, the breathing being mainly or entirely thoracic. The advantages of surgical interference in the early stage of acute appendicitis are as follows: 1. The infective centre, i. e., the appendix, can be removed in many cases before suppuration has taken place, and if it has not perforated or become gangrenous the operation is practically an aseptic one. 2. If pus has formed, even though not encysted and surrounded by a barrier of lymph, it will usually be found to be localized as yet to the neighborhood of the appendix and small in quantity. In these circumstances, its evacuation, together with the removal of the appendix, if followed by free drainage, will usually check the spread of the suppuration which otherwise so often tends to become general. 3. The operation being performed before the onset of general toxæmia (the common cause of death in fatal cases) is usually well borne by the patient. 4. The risks of the later complications of acute appendicitis, viz., subphrenic and hepatic abscess, empyema, parotitis, and phlebitis, and infections in other parts of the body, are greatly minimized. 5. In the early stage the appendix—unless bound down by adhesions the result of a previous attack—lies quite free, and is therefore easily removable. In the later stages, especially in the less acute cases, it is often surrounded and imbedded in a deposit of lymph, which may form part of the wall of an abscess when the pus is encysted. Under these circumstances it is often not easy to recognize the appendix, and its removal is frequently difficult or impossible without breaking down this barrier of lymph, and thus running the risk of infecting the general peritoneal cavity.

1. Infantile Splenic Infection. By the Lecturer, Professor Barr. In Relation to Kala Azar and Infanile Splenic Anæmia. By C. NICOLLE and E. CASSUTO.
2. Cancer and the X Rays. By MALAY.
3. Aspects of Conjugal Diseases. By R. RUMME.

1. **Infantile Splenic Infection.**—Nicolle and Cassuto state that under the name Kala Azar, tropical splenomegaly, dum dum fever, etc., the physicians of India describe an infection which is distinct from paludism, with which it is sometimes confounded, and characterized by irregular fever, progressive anemia, extreme emaciation, digestive troubles, great hypertrophy of the spleen, some hypertrophy of the liver, transient edemas, possible eruptions bounding at the skin, rheumatic pains, and

an always fatal termination. The infection is by the bodies, discovered by Leishmann and also by Donovan in 1903 and described by them in the *British Medical Journal*. Nicolle and Cassuto describe a case which came under their observation in a child of French parentage born in Tunis in 1905, together with the findings at autopsy. Several other cases have been observed which go to show that this disease is to be met with about the Mediterranean as well as in India.

1. Diagnostic and Therapeutic Value of Œsophagoscopy. Study Based on 300 Personal Observations, By GUISEZ.
2. Disinfection of the Uterine Cavity in Puerperal Infection, By A. SCHWAB.

1. **Diagnostic and Therapeutic Value of Œsophagoscopy.**—Guisez urges the invaluable aid afforded in diseases of the œsophagus by œsophagoscopy as well as in the case of application of rational treatment. Particularly he insists that the method is not dangerous or painful. Injury is possible to the walls, which are sometimes very friable, as in cases of cancer and ulcer, or an aneurysm of the arch or of the thoracic aorta may possibly be ruptured, but nevertheless harm is not done in this way, and since its introduction it has been possible to treat successfully certain lesions previously incurable, such as spasms, idiopathic dilatations, cicatricial strictures, and congenital obstructions.

4. Experimental Contributions to the Explanation of the Manner of Working of Bier's Stasis, By VON GRAFF.
5. Serum Studies in Thyreoid Cases, By HOFFMANN.
6. Lysol and Keesol Soap, By SCHOTTELUS.
7. Is There a Specific Precipitate Reaction in Syphilis and Paralysis? By FORNET and SCHERESCHESKY.
8. The Separation of Cholesteroline in the Bile and Its Significance in the Pathogenesis of Gallstones (Continued), By BACHMEISTER.
9. Further Studies Regarding Electricity and Magnetism of the Skin in Man (Concluded), By HARNACK.
10. Obituary of Adelbert von Tobold, By FRANCK.

1. **The Electric Treatment of Cancer.**—Czerny speaks very highly of the method of treatment which he calls fulguration, the application of the high frequency current and of fulguropuncture, in the treatment of cancer. The detailed results certainly seem to be excellent.

2. **Immunization by Mouth.**—Wolf has shown by his experiments that it is not difficult to immunize white mice against mouse typhus by means of a kind of paratyphus given by mouth. Whether it is possible that immunization may be obtained in this way in man against any disease the primary seat of which is in the intestinal canal is not certain, but the numerous mishaps and the impossibility of an exact dosage render it improbable.

3. **Polycythæmia.**—Lömmel reports a case of

America, and discusses at length the clinical picture of the disease, its pathology, pathogenesis, and treatment.

4. **Manner of Action of Bier's Stasis.**—Von Graff has arrived at the following conclusions as the result of his experiments: 1, The component of the stasis which is fatal to bacteria does not depend on a pure humoral action of blood serum and œdema; 2, an antidotal action against poisoning with strychnine or the toxines of tetanus and diphtheria is not proved; and, 3, the œdema, although it possesses in itself only a slight and inconstant bactericidal power, accelerates phagocytosis very markedly.

9. **Electricity and Magnetism of the Skin.**—Harnack has established the following results by his observations: 1, By stroking a nonconductor with the finger tips a person becomes charged with static electricity, and in some individuals with a markedly strong tension after a comparatively very slight exertion of force; 2, with such persons iron and steel objects which they carry with them and frequently take in their hands become to a fairly high degree permanently magnetic; 3, the unrudd skin may exert an effect upon the magnetic needle and other easily movable objects to which it is approached in which the finger behaves neither exactly like a rubbed varnished object, nor exactly like an iron magnet; the signs of this change rapidly; 4, the influences of the living skin in different individuals are of different strengths and are independent, in any individual, of the physiological conditions at the time, i. e., of a full or empty stomach, holding of the breath, or movements. A connection with the internal vital processes is doubtless present.

8. A Fatal Case of Hæmophilia Neonatorum, By H. F. LANGE-ZIEGLER.
9. An Automatic Bottle Warmer, By R. G. FREEMAN.

1. **Pneumohydrothorax.**—Huber states that the view formerly held that gas is secreted by the pleura is now considered improbable, except in rare instances, as from decomposition or the action of the gas bacilli. The almost invariable cause of this condition is perforation from disease of the chest organs, or through the thoracic wall. The most frequent cause is an ulcerative tuberculous focus beneath the pulmonary pleura. It may also be due to perforation of an empyema into a bronchus, giving way to gangrene in the lung, rupture of a pulmonary abscess or hydatid cyst, bronchial ulcerations, and rupture of subpleural emphysematous vesicle. The condition may be precipitated by coughing, vomiting, or any severe strain, or it may come on quietly, even during sleep. From without it may be produced by trauma of various kinds. It is very rare in children, and is usually followed by pleurisy. There is a serofibrinous effusion in most cases. Two

physical signs are absolutely distinctive of this condition: (1) a horizontal upper line of flatness, whatever the patient's position; (2) an immediate change of this level with every change of position.

3. **Hysteria in Children.**—Price states that, while there is no organic change in hysteria, its phenomena may result from an increase of motility in the neuroses. The condition is a very common one among children, especially after the age of six, and among females. Predisposing aetiological factors are heredity, faulty environment, and educational influences, also any condition which lowers the vitality or causes continuous irritation of the nerve centres. The symptoms in children are essentially the same as in adults. The diagnosis is more difficult than in adults, especially in hysterical convulsive seizures. The condition may also be associated with serious nervous disease. The prognosis is usually good. The treatment should consist in suggestion, remembering that there may be an underlying neuropathy, good hygiene, good food, perhaps iron and bromides. Cases are narrated illustrating hysterical tremor, hysterical joint, hysteria of the psychic type, and of the visceral type.

4. **The Rest Treatment in Chorea.**—Ruhräh states that various writers believe that drug treatment in this disease is more effective in the fifth or sixth week than at earlier periods, perhaps because the really serious part of the disease is over by that time, and because drugs are not believed to have any profound influence on the conditions which produce the disease. The author believes that a modified Weir Mitchell rest treatment is the best means now at our command, and is less likely than other measures to be followed by recurrence. The two ends to be reached are (1) rest for both body and mind, (2) increase in the body weight. Daily baths, massage, abundant milk diet, with subsequent meat diet, are the principal measures. Medicines given are castor oil, hydrochloric acid iron, and derivatives of salicyl. This plan was curative in a large number of cases in from ten to seventy-two days.

  12. Chorea and a Convenient and Trustworthy Method of Exhibiting Arsenic Therein, By J. G. SHARP.
1. **The Causes and Operative Treatment of Umbilical and Ventral Hernia.**—Barker attrib-

utes to the great expansion of abdominal surgery the great frequency of ventral hernias. Their occurrence is due not merely to faulty closure of the wound and to suppuration, but to the inherent weakness of scar tissue, and to the unfavorable conditions in which the healing of such wounds often takes place. The cause of umbilical hernia is virtually the same as that of ventral hernia, for it is the weakness of a physiological scar. The protrusion, having once begun, exercises distending force in all directions. In operating for such conditions simple apposition of the edges of the ring will not result in permanent cure. In large hernia the contracted condition of the abdominal cavity will also militate against permanent cure. If there are large masses of omentum in the hernia they should be excised. The sac having been cut away close to the ring, the edges of the ring are united, the stitches including the cut edges of the sac. The author thinks that then a wire filigree should be introduced under the anterior layer of the sheath of the recti and secured by sutures passed through the overlying sheath: a final layer of sutures should then close the skin. A small opening at the lower angle of the wound will facilitate drainage and ensure better results in those who are obese.

3. **Infantile Paralysis.**—Rankin follows Laborde in dividing this disease into (1) an initial stage not exceeding a week; (2) a stationary stage of a week to a month; (3) a regressive stage, from one to six months; and (4) a chronic stage, with atrophy and deformities. He takes for its pathology the summary of Byrom Bramwell, as follows: 1. The lesion is acute inflammation of grey matter in the anterior horn. 2. It is usually confined to this part of the cord. 3. It involves chiefly the lumbar and cervical enlargements, some or all its segments being involved. 4. The lumbar enlargement is the more frequently involved. 5. The inflammation may be very slight or very severe and destructive to the multipolar cells. 6. The inflammation temporarily arrests or permanently destroys the function of the nerve elements, with paralysis to the muscles which they supply. 7. A destroyed nerve cell is never restored. 8. Degeneration and atrophy of the axis cylinder process in the motor nerve endings follow destruction of a nerve cell in the anterior horn, and also the muscular fibres with which the nerve endings are connected.

4. **The Radical Treatment of Cancer of the Prostate.**—Walker finds such treatment favorable from some points of view and unfavorable in others. It is favorable if used early, as the disease in this location progresses slowly. It is unfavorable from the fact that when symptoms arise the disease is usually far advanced and has invaded the bladder or rectum, or both. If an incomplete operation is done in the latter class of cases, early recurrence is almost invariably the rule. The methods which have been used are pararectal, prerectal, lateral perineal, median perineal, and suprapubic. The suprapubic and perineal routes are most frequently followed, the latter the more frequently and with less disastrous results. The most promising cases are those in which there is a precancerous adenomatous period. Unfortunately the true nature of these

growths is often not determinable until after operation, when the tumor is submitted to microscopical examination.

**5. Metastatic Affection of the Pancreas in Mumps.**—Edgcombe states that it has long been known that the pancreas may be involved in the infection of mumps. Various writers have affirmed that parotitis occurring in connection with pancreatic disease is always secondary to the latter. Müller is quoted as stating that mumps may occur in connection with the pancreas, thyroid, thymus glands, and other organs. The author records an epidemic of thirty-three cases of mumps occurring in a boys' school. The disease was mild in type, constitutional symptoms being slight or absent. Orchitis was present in two cases, both the boys having attained puberty. In five of the cases there were symptoms which pointed to metastatic involvement of the pancreas.

**6. Ophthalmia Neonatorum.**—Mayou finds the organism causing this disease occurring in the following order of frequency: (1) *Gonococcus*, (2) *pneumococcus*, (3) *Köch-Weeks bacillus*, (4) *diplobacillus of Morax-Axenfeld*, (5) *bacterium coli*, (6) *Klebs-Löffler bacillus*, (7) *pneumobacillus*, (8) common *pyococci*, (9) *streptococci*, (10) *micrococcus luteus*. There are three classes of the disease: (1) The severe, with profuse discharge and danger to the cornea; (2) the moderate, with *Köch-Weeks conjunctivitis*; (3) the mild, with very little discharge. Infection may take place: (1) Before and during the act of birth, before birth through the unruptured membranes, the eyelids being separated as early as the fifth month. During the act of birth the infectious discharge may be communicated from the cervix or vagina, or by means of the forceps, or the finger of the accoucheur. Infection from the *fœces* is rare. (2) Immediately after birth, hence the necessity of carefully wiping the eyes with bichloride solution and instilling nitrate of silver. (3) Some time after birth, through the medium of the nurse, the diapers, etc. The period of incubation is very short, and the severer the attack the shorter the incubation period.

#### THE JOURNAL OF NERVOUS AND MENTAL DISEASE.

*February, 1908.*

1. The Functions of the Corpora Striata, with a Suggestion as to a Clinical Method of Studying Them,  
By CHARLES L. DANA.
2. General Considerations as to the Nature and Relationship of Hysteria,  
By R. C. WOODMAN.

**1. The Functions of the Corpora Striata.**—Dana remarks that the corpus striatum is an early development from the wall of the anterior vesicle, and its cells are more of the associative and sensory type than motor. It is most closely linked to the optic thalamus and the subthalamic ganglia. It is a ganglion which is present in the lowest of the vertebrate orders, and seems to have functional importance in fishes and reptiles when the pallium is nothing but a layer of epithelial cells. We may suppose it, therefore, to be an older portion of the hemispheres than the cerebral cortex of man. As the cerebral cortex grew in importance, in higher vertebrates, the corpus striatum became less important relatively, and while it, no doubt, has some functions in man, they are probably of an associa-

tive and automatic character, rather than independent and specialized. The author has the notes of four cases, from which he concludes that the corpus striatum has not any independent or specific motor function. It probably has some supplementary motor function, and especially in connection with articulation. It may have some control over the bladder (double lesions), and seems to have some control over vasomotor and trophic conditions of the skin (and lungs?). It has no thermic centre, but it may have some supplementary and associative psychic function, so that lesions affect memory or initiative. It is an organ of less importance relatively in the higher vertebrates. In severe gas poisoning there is a double softening of the lenticular nuclei due to thrombosis of "the artery of cerebral thrombosis," and there result vasomotor and gangrenous conditions of the skin, so that these conditions in connection with a history of coma from gas poisoning form a group of symptoms called "the syndrome of the corpus striatum."

#### Proceedings of Societies.

##### WESTERN SURGICAL AND GYNÆCOLOGICAL ASSOCIATION.

*Seventeenth Annual Meeting Held in St. Louis, December 30 and 31, 1907.*

The President, DR. CHARLES W. OVIATT, of Oshkosh, Wis., in the Chair.

*(Continued from page 330.)*

**Anæsthesia Fatalities in Iowa.**—Dr. L. W. LITIG, of Iowa City, Iowa, said he had sent a circular letter to 3,500 physicians practising in Iowa. Eight hundred replies had been received, many of them containing information which led to reports of fatalities by men who did not reply to his first letter. He had rejected reported chloroform fatalities occurring from two to four days after anæsthesia, because he did not think it was possible to secure anything like reliable data in this class of cases. He had rejected ether fatalities occurring at the close of a long and difficult operation; he had excluded cases in which he thought that the operation itself was of sufficient magnitude to cause death on the operating table or soon after the patient's removal from it. He had excluded obstetric fatalities in which placenta prævia or severe hæmorrhage complicated delivery. He had excluded cases in which pneumonia or other lung complications followed gallbladder or other abdominal work. The report dealt with sixty-three chloroform fatalities. Of these, ten occurred in dental practice. One fatality was due to choking during anæsthesia. There were five fatalities in confinement in which chloroform was used and in which the reporters blamed the chloroform. There was one confinement fatality in which ether was used and in which the reporter blamed the ether. There was one H. M. C., ether, chloroform sequence, and one chloroform ether sequence. There was one late chloroform fatality with jaundice.

The author concluded: 1. That chloroform was vastly more dangerous than ether, and especially in

minor work and at the beginning of the administration. The chloroform ether sequence was especially bad. 2. That in the class of work mentioned chloroform was so much more dangerous than ether that its use should be emphatically condemned, and that "the surgeon (quoting H. C. Wood, writing sixteen years ago or earlier) is not justified in using chloroform except under certain circumstances and for very definite reasons." 3. That chloroform was especially dangerous in dental work and should not be used. 4. That chloroform was not free from danger in obstetric practice.

**The Abdominal Incision.**—Dr. CLIFFORD U. COLLINS, of Peoria, Ill., read a paper on this subject in which he drew the following conclusions: 1. Abdominal incisions should be placed so they would pass through both aponeurosis and muscle. 2. The incision of the aponeurosis and the split in the muscle should run in different directions. This could be done in a large majority of abdominal operations. 3. A longitudinal incision should not be made through the linea alba or the sheath of the rectus at a right angle to the combined pull of the three side muscles when it was possible to avoid it. 4. For very large tumors, in cases where the character and situation were in doubt, the longitudinal incision was probably necessary. 5. If the longitudinal incision was necessary, the split in the rectus should not be continuous with the aponeurotic incision, but should be placed to one side and preferably extend through its inner half to avoid the intercostal nerves which entered the outer half. 6. It would take longer time and more experience to demonstrate the correctness of these conclusions.

**Arthrodesis and Tendon Transfer in Paralytic Club Feet.**—Dr. JOHN PRENTISS LORD, of Omaha, advised arthrodesis and tendon transfer in cases of paralytic club feet for the following reasons: 1. To prevent the return of the deformity, which so often occurred where braces alone were used. 2. To avoid loss of time, during which the child became confirmed in the habit of deformity. 3. Because younger children learned to walk anew much easier than those of more advanced years. Where the patient was financially unable to meet the expense of prolonged treatment with braces. 5. If a return of deformity was prevented, the parents did not fall into the habit of thinking nothing could be done. 6. It utilized to best advantage the remaining muscular power, and gave the best possible results to be obtained in these cases.

The degree of work done depended upon the amount of deformity. Ordinarily, removal of the articular surfaces from the tibioastragaloid, astragalocalcaphoid, and calcaneocuboid was done to effect arthrodesis. In addition, transfer of the tibialis anticus to the common extensor for toe-drop was done while in extreme equinovarus astragalectomy with removal of the joint surfaces from the calcaneocuboid articulation, and even suturing the tibialis anticus to the peroneum on the outer side of the cuboid, might be demanded. In some cases, even the flexor longus hallucis was brought through the interosseous membrane and sutured to the common extensors. In the rare cases requiring muscle splitting, he said, we should avoid covering the transverse nerve fibres in the body of the muscle. Dr.

Lord had used catgut sutures, except where the tension was heavy, when he used fine silk, boiled in bichloride, dried and reboiled in paraffin before the operation. In more than forty consecutive cases cigarette drainage was used to take away oozing. This was gradually removed, no suppurating taking place. Heavy casts were kept applied as long as six months, the use of the foot being gradually increased after three or four months. The results had been very gratifying, the majority of patients having been able to discard braces or crutches within a reasonable time.

**The President's Address.**—PRESIDENT OVIATT did not deal with any concrete surgical problem, but his address consisted of a few thoughts bearing on the practice of surgery that naturally came to one who had spent the most active years of his life in the work. No attempt was made to take up the history further than to show that previous to the year 1800 but few discoveries were made that marked any distinct advance. The evolution of surgery in the past century had kept pace with the development of science along other lines, wonderful as this had been. With the perfected technique of antiseptis and aseptis, it seemed that the acme of surgical science had been reached; but in the light of discoveries it would be rash to attempt to place a limit to the future of surgery.

The ambitious medical student did not usually get far into his college work before he decided to become a surgeon. This decision was brought about largely through what he saw in surgical clinics and from his observation of the position held by the surgical leaders of the profession. Young men who elected to become surgeons should make sure that they possessed the special aptitude and then be willing to devote a long period to preparation for the work.

Attention was called to the fact that there was much that passed under the name of surgery being done by incompetent and ill trained men. Some of it was honest and well intended, but much was for purely commercial ends. A spirit of "graft" had pervaded the profession that was undermining morals and ethics. A partial explanation for the existence of this condition was found in the fact that this was an age of commercialism. We were known to the world as a nation of dollar chasers. This and the overcrowding of the profession with men from inferior schools were in large part responsible for fee splitting and the commission evil. The existence of this class of medical colleges was less excusable when it was considered that the better schools ranked with the best in the world, and that they were ample to afford instruction for all who should enter the profession. Enough well prepared men of character were entering the field to insure the upholding of the lofty ideals that had characterized the profession in the past. We might, therefore, take a hopeful view of the future. Another aid in the elimination of the "graft" evil was coming from the people themselves. The public mind was especially active at this time in combating "graft" in all forms.

The normal standards set for professional men and men in public life were going to be higher in the future, and with the bluntness of public opinion.

turned upon the medical and surgical "grafter" the evil would cease to exist. Hand in hand with this reform it was hoped that an established standard of qualification would be established for those who assumed to do surgery.

**The Significance of Abdominal Tenderness in Locating Lesions of Viscera.**—Dr. T. C. WITHERSPOON, of Butte, Montana, referred to the physiology of the sensory nerves of the abdominal viscera, and discussed at length the effect of lesions of the viscera in the production of pain. The somatic areas of pain referred from the viscera and their significance in diagnosis were pointed out and expatiated upon; likewise the character of the visceral pain. He spoke of disturbance of the sensory function of the somatic nerves, with coincident disturbance of visceral function. Lastly, he called attention to those pains of central origin which were referred to the abdomen. Pott's disease, tabes, and tumors in the spinal canal illustrated this class. Usually the subjective pain was not accompanied by tenderness, at least not of any acuteness.

**The Ætiology of Epithelioma.**—Dr. ARTHUR E. HERTZLER, of Kansas City, Mo., began with the hypothesis that the limitation of epithelial cell development was set by the chemical difference in the basement membrane and epithelial cells. Experiments proved that those chemicals which united with (stained) connective tissue *in vivo* caused an atypical epithelial cell proliferation resembling closely a beginning epithelioma. The development of atypical cells was limited because the action of the chemical upon the connective tissue was limited. This resulted in constancy for stains having these characteristics. It was negative for connective tissue stains which did not stain *in vivo* or for nuclear stains. In areas in which atypical cell proliferation had been brought about by such means the fibres, after fixation, did not stain with the ordinary fibrous tissue stains, while the fibrous tissue in regions not so treated stained in the characteristic manner.

Applying facts so deduced clinically, the general statement was ventured that epitheliomas occurred in those regions where alkaline secretions were permitted to come in contact with the fibrous tissue by irritation, thus producing the resistance of the connective tissue to the invasion of epithelial cells or to some exposure to leucocytes, as in chronic inflammation, or to some overstimulation of the epithelial cells. Either of these conditions would lead to a disturbance of chemical balance and permit the invasion of the epithelium.

**Preparatory and Postoperative Treatment.**—Dr. JAMES E. MOORE, of Minneapolis, said that as a rule preparatory and postoperative treatment, aside from the sterilization of the operative field and the dressing of the wound, had more to do with the comfort of the patient than with his recovery, for emergency patients very commonly did well and surgeons frequently performed successful operations away from home and left the after treatment to a physician little skilled in the care of surgical cases. In all but exceptional cases, where some organ—the bladder, for example—had to be prepared for operative procedures, prolonged preparatory treatment was unnecessary and inadvisable. It was not in keeping with modern surgery that sur-

geons should operate upon their patients off the street, but it was sufficient to have the average patient enter the hospital on the day preceding the operation. In weak patients and where a very severe operation was to be performed, a hypodermic of 1/30 of a grain of strychnine just before the operation was helpful. The operative field should be shaved and thoroughly disinfected and a sterile dressing applied the evening before the operation. Every operating room should have an experienced anaesthetist, because it added to the patient's comfort and safety, and allowed the surgeon to give his undivided attention to the operation. He pointed out the many things pertaining to the operation itself which had a decided bearing on the after treatment. The patient always thought the stitches and bandages were too tight, and it was very important that the surgeon should know that they were not. Most stitch abscesses were caused by tight sutures, and tight bandages were the cause of untold suffering. Thirst was the greatest source of suffering after an operation, and in the management of this symptom many mistakes were made. His patients all got water after an operation, and they got well much more comfortably than those who were deprived of it. All surgeons agreed that the patient was better without food for a time after an operation, for they did not suffer from hunger, and an effort to force feeding would surely disturb the stomach. Aside from opiates and mild cathartics, medicine had very little place in postoperative treatment. His patients got it only to meet definite indications. Attention should be given to the relief of pain after an operation. The proper care of the bowels had much to do with the patient's comfort.

In every case the question naturally arose, When shall the patient get out of bed? All were agreed that old people should get up at the very earliest period possible, for reasons well understood, but there was still a great diversity of opinion as to when a younger patient should get up. Every abdominal operation was of sufficient importance to justify the patient in remaining in bed for from one to three weeks, according to circumstances, and he was usually content to do so. There was no crying need of getting the patient out of bed on the day after an abdominal operation. He was safer and more comfortable in bed for a few days at least. The author had recently operated upon a colleague for chronic appendicitis, and he made the statement that he intended to get out of bed on the day after the operation, saying that staying in bed for a week after such a simple operation was all nonsense, to all of which the speaker readily acceded, with a mental reservation. On the first day the patient quietly curled upon his side, and Dr. Moore smiled without comment. On the second day he was still in bed, and when he asked him why he was not up, he mildly suggested that he go to a warmer climate, and very emphatically stated that his viewpoint had changed.

**The Appendix in a Femoral Hernia.**—Dr. CHARLES S. JAMES, of Centerville, Iowa, reviewed the literature, after which he reported the case of a woman, aged seventy-seven years, who for four days had noticed a painful lump in the right groin. She had been in her usual health previously, but had noticed a small lump at this point for several

years. The symptoms were negative, except that the pulse was 96 and the temperature  $102^{\circ}$ . The abdomen was not distended. There was nothing noted indicating an intraabdominal lesion. There was a prominent brawny swelling, three and a half to four inches in diameter, indurated and semi-fluctuant, presenting the characteristic appearance of a suppurative gland over Poupart's ligament. There was no impulse. A diagnosis was made of a local suppurative process, with probable femoral hernia. An operation was performed at the Centerville Hospital an hour later under spinal anaesthesia, using 10 centigrammes of 10 per cent. stovain solution. The abscess cavity was dissected up with difficulty and the appendix was found to extend through the femoral hernial opening. A separate abdominal incision disclosed an incarcerated loop of ileum, gangrenous, and two perforations. He resected five inches of the intestine and resorted to end to end anastomosis with suture. The appendix was ligated, severed, and removed, with the closure of the stump in the usual manner. Both incisions were closed with continuous catgut suture. The time of the operation was an hour and a quarter. The patient was conscious, but suffered no pain throughout the operation. Convalescence was pleasant and recovery excellent. He presented photographs and the specimen.

(To be concluded.)

### Book Notices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

*The Operating Room and the Patient.* By RUSSELL S. FOWLER, M. D., Professor of Surgery, Brooklyn Post-graduate Medical School, etc. Second Edition, Revised, and Enlarged. Philadelphia and London: W. B. Saunders Company, 1907. Pp. 284. (Price, \$2.)

This book appeared for the first time a little over a year ago, when it was well received and appreciated by the medical profession. The author now places a second edition before his confrères, in which he has added a chapter on the general consideration in the after treatment and another on complications of wound infection. The book contains twelve chapters, and treats the subject in the following way: The operation room and its personnel; the instrument and supply room, giving also a full list of instruments and dressings commonly employed; anaesthesia; the patient; after treatment; aseptic wounds; infections; complications. The book can be well recommended, as it contains many useful hints and instructions.

*Faithful of Organic Chemistry for Medical Students.* By Dr. G. V. BLISSON, Professor of Physiological Chemistry in the University of Basel. Translated with Additions by R. H. ADAMS, Ph.D., D. Sc. (London), Assistant Professor of Physiological Chemistry and Fellow of University College, London. London and New York: Longmans, Green, & Co., 1907. Pp. xvi+260.

As indicated by the title, this book is intended for the equipment of medical students with a working knowledge of the science of organic chemistry. In the series of seventeen lectures which make up its contents, almost every branch of organic chemistry

that has the slightest application in physiology, pathology, pharmacology, or hygiene is included, and the author points out in which branch of medicine the selected facts of the lectures find application. The value of the book is much enhanced by the additions and transpositions which have been made by the translator, and though the subject as presented in the lectures may wear a formidable look to medical students and others who enter on the study for the first time, it is yet ideally adapted to its purpose and is well calculated to fulfill the hope of the translator that by its study organic chemistry may be brought nearer to physiological chemistry. The arrangement and general plan of the lectures are attractive and the subject matter is readable enough, but we fear that a little too much elementary knowledge of the science of organic chemistry, on the part of the average medical student, is presupposed by both author and translator.

*A Textbook of Diseases of the Nose and Throat.* By D. BRADEN KYLE, A. M., M. D., Professor of Laryngology and Rhinology, Jefferson Medical College, etc. 219 illustrations, 26 of Them in Colors. Fourth Edition, Thoroughly Revised and Enlarged. Philadelphia and London: W. B. Saunders Company, 1907. Pp. 797.

On its first appearance we recommended Kyle's textbook as particularly well suited to students, and called attention to the excellence of the chapters on examination, diagnosis, and anatomy. These have been revised and amplified. The whole subject of local disease and of operative methods, has been brought up to the latest standpoint, and there are a number of entirely new chapters, among which the most important are those on the surgery of the larynx, bronchoscopy, the physiology and pathology of the voice, speech defects, and the relation of the voice to hearing. Radiography has not received from the author the attention it deserves as a diagnostic measure, only cursory mention of it being made. The x ray is a valuable aid in many cases in which bronchoscopy shows nothing or cannot be employed. It should be made a routine measure where a foreign body is suspected, and in all obscure and long continuing cases, as well as invariably before operative procedures on the accessory sinuses. The curative effects of this agent might also have been mentioned, considering the results obtained by its application in rhinoscleroma, epithelioma, and other serious affections of the upper respiratory tract.

*Diseases of Children for Nurses.* Including Feeding, Therapeutic Measures Employed in Childhood, Treatment for Emergencies, Prophylaxis, Hygiene, and Nursing. By ROBERT S. MCCOMBS, M. D., Assistant Physician to the Dispensary and Instructor of Nurses at the Children's Hospital of Philadelphia, etc. Illustrated. Philadelphia and London: W. B. Saunders Company, 1907. Pp. 473. (Price, \$2.)

The scope of this work is well defined by its title, and a reading of it shows that the author has admirably fulfilled his purpose. It is strictly a book for nurses. Short descriptions of the various diseases of infants and children are given, and should aid in rendering a nurse intelligent regarding her cases. It is certainly desirable that a nurse should have a sufficient knowledge of disease to know what symptoms are to be expected and what complications are to be guarded against. A sufficient knowledge of treatment is also necessary to enable her

her the reasons for the measures adopted and to render her intelligent in their application. Following this section of the book is special instruction upon the nursing of various diseases or classes of diseases. The subject of infant feeding is, on the whole, very satisfactorily presented, and is well adapted to the nurse's use. The chapter on therapeutics must prove one of practical value to the nurse. The portions devoted to the methods of applying the various measures used in the treatment of children are well managed and must also prove valuable. The book, on the whole, is an excellent work for the use of nurses, and in some particulars covers a field which has not been heretofore written upon.

#### BOOKS, PAMPHLETS, ETC., RECEIVED

The Production and Handling of Clean Milk. By Kenelm Winslow, M. D., M. D. V., B. A. S. (Harv.), Formerly Instructor in Bussey Agricultural Institute and Assistant Professor in the Veterinary School of Harvard University, etc. New York: William R. Jenkins Company, 1907. Pp. 207. (Price, \$2.50.)

Diseases of the Breast. With Special Reference to Cancer. By William L. Rodman, M. D., LL. D., Professor of Surgery in the Medicochirurgical College of Philadelphia, Professor of Surgery in the Woman's Medical College of Pennsylvania, etc. With Sixty-nine Plates, of which Twelve are Printed in Colors, and Forty-two Other Illustrations. Philadelphia: P. Blakiston's Son & Co., 1908. Pp. 385. (Price, \$4.)

Healthy Boyhood. By Arthur Trewby, M. A. With an Introduction by Sir Dyce Duckworth, M. D., LL. D., Consulting Physician to St. Bartholomew's Hospital, etc., and a Foreword by Field Marshal Earl Roberts, K. G., K. P., V. C., O. M., P. C., G. C. B., G. C. S. I., G. C. I. E., D.C.L., LL. D. New York: Longmans, Green, & Co., 1907. Pp. 63.

Practice of Medicine for Nurses. A Textbook for Nurses and Students of Domestic Science, and a Handbook for all Those Who Care for the Sick. By George Howard Hoxie, A. M., M. D., Professor of Internal Medicine in the University of Kansas, etc. With a Chapter on The Technic of Nursing, by Pearl L. Laptad, Principal of the Training School for Nurses of the University of Kansas. Philadelphia and London: W. B. Saunders Company, 1908. Pp. 284.

Report of the Commissioner of Education for the Year Ending June 30, 1906. Volume 2. Washington: Government Printing Office, 1908. Pp. 1308.

La Lutte contre les microbes. Cancer, tuberculose, maladie du sommeil, tétanos, entérite et microbes intestinaux, varicelle et vaccine: L'Œuvre de Jenner. Par Dr. Etienne Burnet, de l'Institut Pasteur, chef du service de la vaccination de la Ville de Paris. Paris: Armand Colin, 1908. Pp. 318.

Die Entzündung: eine monographische Skizze aus dem Gebiet der pathologischen Physiologie. Von Dr. Rudolf Klemensiewicz, o. ö. Professor u. Vorstand des Instituts für allgemeine Pathologie an der Universität in Graz, etc. Festschrift der k. k. Karl-Franzens-Universität in Graz aus Anlass der Jahresfeier am 15. November 1905. Jena: Gustav Fischer, 1908. Pp. vii-120.

Klinische Semiotik. Mit besonderer Berücksichtigung der gefährdenden Symptome und deren Behandlung. Von Dr. Alois Pick a. o. Universitätsprofessor, k. u. k. Oberstabsarzt, und Dr. Adolf Hecht, Kinderarzt. Wien und Leipzig: Alfred Hölder, 1908. Pp. 960.

Hematological Atlas. With a Description of the Technic of Blood Examination. By Priv. Doz. Dr. Karl Schleich, Scientific Assistant in the Medical Clinic University of Freiburg i/B. English Adaptation of the Text by Frederic E. Sondern, M. D., Professor of Clinical Pathology, New York Postgraduate Medical School and Hospital, etc. With Seventy-one Colored Illustrations. New York: Rebman Company, 1908. Pp. 256. (Price, \$10.)

Milk and Its Relation to the Public Health. By Various Authors. Bulletin No. 41. Hygienic Laboratory, Public Health and Marine Hospital Service of the United States. Washington: Government Printing Office, 1908. Pp. 757.

## Miscellany.

**Resolution on the Death of Dr. Robert W. Taylor.**—The following obituary notice was approved at the meeting of the Dermatological Society, held on February 25, 1908:

#### ROBERT W. TAYLOR.

Born August 11, 1842. Died January 5, 1908.

Dr. Taylor was one of the founders of the New York Dermatological Society, the oldest dermatological association in existence. Since its organization in 1869, to the meeting held shortly before his death, and at which he was present, he has always been one of its most zealous members. An indefatigable student, an earnest and convincing teacher, and a brilliant and prolific writer, his death will not only be keenly felt by those who had the opportunity of working with him and profiting by the example of his energy and enthusiasm, but will be regarded as an irreparable loss to the medical profession. Among the eminent names which have been inscribed upon the muster roll of our society Dr. Taylor's name will ever rank high. No member has been more faithful in the discharge of his duties, and no one, by his professional achievements, has shed greater lustre upon its membership.

In our grief at the thought that he will meet with us no more, we feel that we have lost not only a very distinguished colleague, but a most estimable friend.

GEORGE HENRY FOX,  
HERMANN G. KLOTZ,  
EDWARD B. BRONSON,  
Committee.

**Symposium.**—Dr. A. Rose writes in a letter to the editor of the *Medical Review of Reviews*: "Will you kindly permit me to call your readers' attention to the wrong interpretation of the word 'symposium,' which we find so frequently on programs of medical writers? *Symposium* (τὸ συμπόσιον) is a banquet, a feast, and one of the features of such banquet or feast is drinking together (συμπίνειν-δύν, τινα) Συμποτής (δύν, ποτής) is one with whom we drink in company. I know very well that in English language is understood by symposium a collection of opinions or essays, but this is incorrect. Incorrectness of such kind may creep in every living language, but in all civilized countries there are men of taste—in Germany and France there are even patriotic societies—who exert themselves to eliminate from the language whatever has been found incorrect."

**Illumination of the Battlefield for the Search of Wounded.**—Dr. Willcox has translated an article of Dr. Fluteau, of the French army, which appears in *The Military Surgeon* of December, 1907. Several lights were tried and it was proved by these trials that the Blieriot acetylene-lamps produced a light fully equal to the easy discovery of the wounded, hidden as well as they could have been on the battlefield. The second lantern constructed, that gave a more brilliant light than the first, is a trifle too large, but it is a fault it would be difficult to remedy without injuring its qualities. It also presents certain defects in construction, such, for example, as the employment, for closing the ap-

paratus, of a rubber washer that can be changed in length. It will be possible, according to the maker, to replace this with a beaten out leather plate. The Brenot-Mareschal lamp is simple, light, not cumbersome, but it presents one great fault. To put it in operation it requires, as does the Paquelin thermocautery, the working of a rubber bulb by hand. There results a fatigue that does not allow it to be used sufficiently long for the purpose that it is meant for. Moreover, the inflation of the rubber bulb is a difficult task, and it is liable to alteration in spite of the precautions adopted for apparatus of this kind that form part of the sanitary service material in the field.

**The Relation of Upper Respiratory Obstruction to Oral Deformity.**—Faught observes that the ætiology of the general subject of dental irregularity, and particularly the interrelation of such deformity and chronic respiratory disturbances, is still lacking a definite basis. This matter should receive particular attention at the hands of every dentist. Dental irregularity in the vast majority of instances is associated with, if not dependent on, upper respiratory obstruction. Dental practitioners should be more familiar with the common forms of upper respiratory obstruction, their symptoms, diagnosis, and treatment. The comparative study of the changes brought about through corrective procedures should be more carefully studied, and more accurate methods of measuring and recording them devised. The rational treatment of dental irregularity should include preliminary examination and treatment of the nasal chambers and pharynx. The result of the ordinary expansion operation on nasal conditions is more dependent on vital tissue in the nasal region than on mere mechanical movement. Operations designed mechanically to increase the respiratory capacity of the nasal passages are practically valueless unless the intermaxillary suture is separated, as shown by increase of space between the central incisors. It is impossible to relieve stenosis due to adenoids or septal irregularities by expansion methods. Adenoids and deviations of the septum should receive the usual treatment at the hands of the rhinologists prior to the correction of dental irregularity. The stimulation of vital forces and renewed growth in the nasal chambers, together with the restoration of normal conditions in contiguous parts, are the chief causes of improvement following the expansion operation.—*Journal of the American Medical Association.*

### Official News.

#### Public Health and Marine Hospital Service Health Reports:

The following tables of smallpox, measles, typhoid and other diseases are submitted to the Surgeon General, United States Public Health and Marine Hospital Service, during the week ending February 20, 1908.

Place.	Date.	Cases.
California—San Francisco	Feb. 18	1
Idaho—Boise	Feb. 18	1
Illinois—Chicago	Feb. 18	1
Indiana—Indianapolis	Feb. 18	1
Missouri—St. Louis	Feb. 18	1
Nebraska—Omaha	Feb. 18	1
North Dakota—Grand Forks	Feb. 18	1
South Dakota—Sioux Falls	Feb. 18	1
Texas—San Antonio	Feb. 18	1
Washington—Seattle	Feb. 18	1

Ohio—Cincinnati	Feb. 18	1
Ohio—Warren	Feb. 18	1
Oregon—Portland	Feb. 18	1
South Dakota—Sioux Falls	Feb. 18	1
Tennessee—Nashville	Feb. 18	1
Texas—San Antonio	Feb. 18	1
Washington—Spokane	Feb. 18	1

#### Smallpox—Foreign.

Cape Colony—East London	Jan. 4-11	2
Japan—Kobe	Jan. 14-18	1783
Japan—Nagasaki	Jan. 14-18	3
Japan—Yokohama	Jan. 14-18	40
Java—Batavia	Dec. 21-Jan. 18	9
Mexico—Aguas Calientes	Jan. 26-Feb. 2	1
Mexico—Mexico City	Jan. 24-1	2
Netherlands—Rotterdam	Jan. 18-25	1
Portugal—Lisbon	Jan. 18-25	2
Russia—Batoum	Jan. 18-Feb. 2	23
Russia—Libau	Feb. 1-8	1
Russia—Moscow	Jan. 4-8	57
Russia—Odessa	Jan. 21-28	12

Peru—Trujillo	Jan. 18	26

#### Public Health and Marine Hospital Service:

Official list of changes of stations and duties of commissioned and noncommissioned officers of the United States Public Health and Marine Hospital Service for the seven days ending February 20, 1908.

DEGADE, J. M., Acting Assistant Surgeon. Granted two days' leave of absence on account of sickness from February 7, 1908.

HALLETT, E. B., Acting Assistant Surgeon. Granted leave of absence for thirty days, on account of sickness, from January 8, 1908, and seven days' leave of absence from February 7, 1908.

KEATLEY, H. W., Acting Assistant Surgeon. Granted leave of absence for seven days from February 11, 1908, under paragraph 210, Service Regulations.

ROBERTS, NORMAN, Assistant Surgeon. Granted leave of absence for three days from February 24, 1908, under paragraph 191, Service Regulations; granted leave of absence for twenty-three days from February 27, 1908.

SIMONSON, G. T., Acting Assistant Surgeon. Granted leave of absence for one day, February 21, 1908.

WALKER, T. D., Acting Assistant Surgeon. Granted leave of absence for ten days from February 25, 1908.

#### Army Intelligence:

Official list of changes in the Army for the week ending February 20, 1908.

COWLEY, H. W., First Lieutenant and Assistant Surgeon. Resignation of commission as an officer of the Army accepted, effective March 18, 1908, and granted leave of absence to and including above date.

MOORE, J. R., Major and Surgeon, 1st Reg. Cavalry. Kept with troops assigned to San Francisco, Cal.

MURPHY, J. L., Major and Surgeon, 1st Reg. Cavalry. Kept with troops assigned to San Francisco, Cal.

NELSON, KENT, Captain and Assistant Surgeon. Ordered to proceed to Fort Thomas, Ky., for duty to accompany the Fourth Infantry from that post to San Francisco, Cal.

PURNELL, H. S., Captain and Assistant Surgeon. Ordered to accompany First Battalion, Fourth Infantry, from Fort Mackenzie, Wyo., to San Francisco, Cal., and then to return to his proper station.

TALBOTT, E. M., Captain and Assistant Surgeon. Granted ten days' leave of absence.

The following named medical officers are detailed as members of boards of officers, to meet at the posts designated, on April 14, 1908, or as soon thereafter as practicable, to examine such applicants for commission in volunteer forces as may be authorized to appear before them:

ASHBURN, P. M., Captain and Assistant Surgeon. Fort Banks, Mass.

BAKER, F. C., Captain and Assistant Surgeon. Fort Oglethorpe, Cal.

BANISTER, J. M., Lieutenant Colonel and Deputy Surgeon General. Fort Riley, Kan.

DAVIS, W. B., Lieutenant Colonel and Deputy Surgeon General. Fort Crook, Neb.

DE SHON, C. D., Major and Surgeon. Fort Logan H. Roots, Ark.

EWING, C. R., Major and Surgeon. Fort Oglethorpe, Cal.

FORD, J. H., Captain and Assistant Surgeon. Fort Mackenzie, Wyo.

FREEMAN, P. L., Lieutenant Colonel and Deputy Surgeon General. Fort Riley, Kan.

GRISSINGER, J. W., Captain and Assistant Surgeon. Fort Banks, Mass.

HANSELL, H. S., Captain and Assistant Surgeon. Fort Crook, Neb.

HARVEY, P. F., Colonel and Assistant Surgeon General. Fort Sheridan, Ill.

HUNTINGTON, P. W., Captain and Assistant Surgeon. Fort Rosecrans, Cal.

KEEFER, F. R., Major and Surgeon. Fort Rosecrans, Cal.

KENDALL, W. P., Major and Surgeon. Fort Sam Houston, Texas.

KIRKPATRICK, T. J., Captain and Assistant Surgeon. Fort McPherson, Ga.

LEWIS, W. F., Captain and Assistant Surgeon. Fort Logan H. Roots, Ark.

MONCRIEF, W. H., First Lieutenant and Assistant Surgeon. Fort McPherson, Ga.

MUNSON, E. L., Major and Surgeon. Fort Sheridan, Ill.

PURNELL, H. S., Captain and Assistant Surgeon. Fort Mackenzie, Wyo.

WHALEY, A. M., First Lieutenant and Assistant Surgeon. Fort Sam Houston, Texas.

## Navy Intelligence:

*Official list of changes in the medical corps of the United States Navy for the week ending February 29, 1908:*

ALLEN, A. H., Assistant Surgeon. Will stand relieved from duty in Cuba upon arrival at Lajas, province of Santa Clara, of Passed Assistant Surgeon R. E. Riggs, and will comply with orders from the Navy Department.

BROWN, E. W., Assistant Surgeon. Ordered to the Naval Medical School, Washington, D. C.

CLIFFORD, A. B., Passed Assistant Surgeon. Detached from the Naval Medical School Hospital, Washington, D. C., and ordered to the Naval Hospital, New Fort Lyon, Colo., March 12.

DOWNER, J. O., Assistant Surgeon. Unexpired portion of leave revoked; ordered to the *Relief*.

MEANS, V. C. B., Surgeon. Retired from active service February 22, 1908, under the provisions of Section 1453, revised statutes.

MORAN, C. L., Assistant Surgeon. Appointed an assistant surgeon from February 10, 1908.

MUNSON, F. M., Passed Assistant Surgeon. Ordered to the *Barry*.

RIGGS, R. E., Passed Assistant Surgeon. Will proceed from Camp Columbia, province of Havana, to Lajas, Cuba, for duty.

STANLEY, A. C., Assistant Surgeon. Appointed an assistant surgeon from February 10, 1908.

TRIMBLE, A. C., Assistant Surgeon. Detached from the *Barry* and ordered home.

## Births, Marriages, and Deaths.

### Born.

DE WITT.—In Whipple Barracks, Arizona, on Saturday, February 15th, to Dr. Wallace De Witt, United States Army, and Mrs. De Witt, a son.

### Married.

CULLER—LOSER.—In Philadelphia, on Wednesday, February 12th, Dr. Robert M. Culler, United States Army, and Miss Anne E. Loser.

DILMORE—MINES.—In Philadelphia, on Wednesday, February 26th, Dr. George S. Dilmore and Miss Sarah Hall Mines.

FALLER—GIMBEL.—In St. Louis, Missouri, on Monday, February 24th, Dr. Albert Faller and Miss Hortense Gimbel.

FARLEY—LUMLEY.—In Philadelphia, on Wednesday, February 26th, Dr. Joseph Farley and Miss Lillian E. Lumley.

LONGMORE—DALGLEISH.—In Ottawa, Canada, on Wednesday, February 26th, Dr. John Alva Longmore, of Brooklyn, and Miss Lillian Llewellyn Dalgleish.

PRICE—FRANCIS.—In Brooklyn, on Tuesday, March 3d, Dr. William Harrison Price and Miss Anna Francis.

RINGLAND—SNEDECOR.—In Brooklyn, on Friday, February 21st, Dr. Robert Finley Ringland, of Bloomfield, New Jersey, and Miss Elizabeth Van Buskirk Snedecor.

SMITH—RESSLER.—In Philadelphia, on Saturday, February 22d, Dr. Frank W. Smith, of Passaic, New Jersey, and Miss Florence M. Ressler.

### Died.

AVERY.—In Chicago, Illinois, on Tuesday, February 18th, Dr. Samuel J. Avery, aged eighty years.

BEDEL.—In Norfolk, Nebraska, on Monday, February 17th, Dr. Marshall D. Bedel.

BOONE.—In Frederick, Maryland, on Saturday, February 22d, Dr. Jermingham Boone, aged eighty-seven years.

COVERLY.—In Brooklyn, on Monday, February 24th, Dr. John Henderson Coverly, aged sixty-five years.

DODGE.—In Tacoma, Washington, on Saturday, February 22d, Dr. Maurice M. Dodge, aged sixty-six years.

FITZGERALD.—In New York, on Thursday, February 27th, Dr. Charles F. Fitzgerald, aged thirty-five years.

HALSTED.—Newark, New Jersey, on Sunday, February 23d, Dr. Alfred T. Halsted, aged forty-five years.

INGRAM.—In Murphysboro, Illinois, on Thursday, February 20th, Dr. William T. Ingram, aged seventy-eight years.

KRAMER.—In Louisville, Kentucky, on Sunday, February 23d, Dr. William F. Kramer, aged forty years.

MCMASTER.—In Toronto, Canada, on Thursday, February 20th, Dr. John McMaster, aged forty-nine years.

MANGUM.—In New York, on Sunday, February 23d, Dr. Joseph Young Mangum.

MILLER.—In Needham, Massachusetts, on Saturday, February 22d, Dr. Vesta D. Miller.

NETTLETON.—In Rochester, New York, on Friday, February 21st, Dr. H. R. Nettleton, aged sixty years.

PROBASCO.—In Plainfield, New Jersey, on Tuesday, February 25th, Dr. John B. Probasco, aged sixty-six years.

RICE.—In Newmarket, Virginia, on Saturday, February 22d, Dr. F. E. Rice, aged seventy-four years.

ROBINSON.—In St. Augustine, Florida, on Saturday, February 22d, Dr. George A. Robinson, of Sayville, Long Island, aged fifty-seven years.

ROSS.—In Madisonville, Kentucky, on Wednesday, February 26th, Dr. W. S. Ross, aged seventy-eight years.

SAUNDERS.—In Memphis, Tennessee, on Monday, February 23d, Dr. Dudley Dunn Saunders, aged seventy-three years.

SONNENSCHMIDT.—In Washington, D. C., on Friday, February 28th, Dr. Charles W. Sonnenschmidt, aged seventy-six years.

TRIMBLE.—In Baltimore, Maryland, on Monday, February 24th, Dr. Isaac Ridgeway Trimble, aged forty-eight years.

#### ACUTE FLEXURES OR ANGULATIONS OF THE SIGMOID AND COLON.

By JAMES P. TUTTLE, M. D.,  
New York.

The rôle in the production of disease which is attributed by internists at the present time to the absorption of toxins from retained, fermenting, or putrefying fecal matter, renders any study which throws light upon the causes and relief of these conditions both interesting and important. Without minimizing the importance of other factors, I would call attention to the influence of acute flexures or angulations of the colon and sigmoid in the causation of constipation and fecal retention. The term *acute* is used here in the geometrical sense as the obverse of obtuse, and not in the medical, for acute flexure or angulation is usually a chronic condition of slow origin. The term itself describes the condition, a sudden or sharp bend of the gut upon itself, such as in all hollow tubes narrows or obliterates the calibre according to its degree. These angulations are anatomical throughout the colon, and all will recognize the terms *hepatic flexure*, *splenic flexure*, *sigmoid flexure*, *rectosigmoidal flexure*. In normal conditions these flexures retard to a slight degree the fecal current, and when through displacement or any other cause the bend is exaggerated the obstruction is proportionately increased. Thus, in gastroenteroptosis the transverse colon is carried downward in the abdominal cavity and unless the ligaments give way, the normal hepatic and splenic flexures become more and more acute and obstructive as the colon descends. (Fig. 9). This accounts for the distention and tenderness over the cæcum in such cases. In many instances of this kind the right kidney and hepatic flexure descend along with the transverse colon, and then only the splenic flexure is accentuated. (Fig. 2).

#### Causes.

These two flexures are no doubt physiological, and are produced by a short mesentery and retaining band, the ligament, at the angle and a more or less long mesentery on either side of it. Now, this throws some light upon the causation of abnormal and pathological flexures elsewhere. A shortening of the mesentery by inflammation or adhesion or the fixation of the gut by adhesion may either or both together cause angulation which will narrow or even obliterate the intestinal calibre. The sigmoid flexure is so irregular in its anatomical con-

formation, and in the length and attachment of its mesentery, and it is so liable to inflammation arising in itself or extending to it from the pelvic organs with which it is in constant apposition, that it is the most frequent seat of all exaggerated flexures, both congenital and acquired. It is with these that I have had chiefly to deal, and I shall not theorize, but briefly describe only those conditions which I have seen and operated upon.

#### History.

It was before the American Proctologic Society, in 1899, that I first publicly called attention to acute flexures of the sigmoid as a frequent cause of constipation. In 1901, I described the condition, (*International Journal of Surgery*), and again in my work on *Diseases of the Anus, Rectum, and Pelvic Colon*, first edition, 1902, the subject is referred to several times and the technique of treatment is detailed. Delatour (*Annals of Surgery*, xlii, p. 678, 1905), and Laroque, (*Ibid.*, xliv, p. 678, 1906) evidently not having seen my descriptions, have published five interesting and descriptive cases, which they thought were the first recognized. Delatour even says: "Angulation of the intestinal canal at the sigmoid is a pathological condition which we believe exists, but it has not been described." Niles, (*Journal of the American Medical Association*, September 15, 1906), refers to acute and temporary angulations as the result of ulceration of the sigmoid. He reports and depicts two cases in which acute angulation of the sigmoid with the descending colon was caused by ulceration at this point; and states that the bowel walls gave way on attempts to restore them to position. Reis, (*Annals of Surgery*, 1904), in a most interesting article on Mesosigmoiditis in Its Relation to Recurrent Volvulus, relates a case which appears from his description to be one of recurrent angulation rather than volvulus. It would be splitting hairs to argue the point whether a volvulus always consists in a twist, or whether it may not be an acute angulation or flexure. The fact which he proves, viz: that inflammation in the mesosigmoid may produce a thickening and contraction which will cause such twists or angulations as will partially or completely obstruct the passage, is most interesting and instructive.

#### Ætiology.

These flexures may be congenital or acquired.

The congenital type are all, with one exception so far as I have observed, due to the turning of the rectum to the left at its upper end and thus bringing the two fixed ends of the sigmoid in such close apposition that the long loop in between is neces-

sarily acutely flexed, either when it rises up into the abdominal cavity, or drops down into the pelvis, or folds over upon itself, as is shown in Figs. 2, 3, 4. The case of congenital angulation which differed

FIG. 1.—Extensive adhesions of the sigmoid to the vertebral column, transverse, and descending colon, causing acute flexures at two points.

from this, consisted in the fixation of the sigmoid on the right side of the pelvis, and its sudden turn backward along the promontory of the sacrum to join the descending colon. These malformations are, I believe, the origin of most of the cases of hypertrophied and distended sigmoid and colon so often seen in children. Sigmoiditis and perisigmoiditis are the chief causes of acquired angulation. Ulcers of the sigmoid, as has been so well described by Niles, may cause angulation either by their cicatricial contraction or by the inflammation extending to the peritonæum, and causing adhesion or fixation of the gut at some abnormal point. (Fig. 7). Perisigmoiditis may also arise from traumatism by the action of the iliacus and psoas muscles, as has been pointed out by Bryon Robinson, and in this state the gut may become adherent to almost any point in the abdomen, thus causing an acute flexure with partial or complete obstruction. Mesosigmoiditis as described by Reis may, also account for the condition through shortening of the mesentery and thus causing abnormal fixation of the gut. Inflammation of the pelvic organs, oophoritis, salpingitis, etc., may extend to the sigmoid and cause adhesions and angulations of any degree. (Fig. 9). These are, I believe, the most frequent causes, and they account for the so much greater frequency of the condition in women than in men. Local or general peritonitis of any type may bring about the condition when there is no disease in the sigmoid itself. A marked illustration of this was found by the writer in the case of a young woman. Ad-

hesions between the appendices epiploicæ may cause acute angulation with most distressing symptoms (Fig. 7). I have observed this condition twice. Chronic appendicitis, if not a cause, is at least a comparatively frequent complication of acute flexure on the right side. (Fig. 9).

#### *Symptoms.*

There is always constipation or fæcal stasis; distention and more or less tenderness over the cæcum, often leading one to suspect chronic appendicitis. The latter may be the cause, and it may have caused the angulation, (See Fig. 6); but the removal of the appendix alone will not cure the patient. The flexure must be straightened out at the same time or there will still be fecal obstruction. May this fact not account for some of the cases of fatal obstruction after appendicectomies? As to the other symptoms, they are local, constitutional, and include the whole category of reflex phenomena associated with obstructed bowel movements. In the congenital type, which the specialists rarely see in early life, there is always a history of colic, distended abdomen, constipation, and indigestion. As the child grows up it is called anæmic or chlorotic, but is really toxic from absorption of the products of retained feces. If a girl, there is usually delayed or irregular menstruation, imperfect development, and often intractable leucorrhœa. The constipation, flatulence, and colicky attacks persist.

In one such case the girl at seventeen years of age weighed only seventy-eight pounds, and though her menstruation appeared at twelve years of age and was always painful, it had never been more than a few drops. Two years after operation this function was normal, and the patient weighed 105 pounds. In this case the deformity was due to too

FIG. 2.—Acute flexure of the sigmoid due to adhesion of two appendices epiploicæ, causing almost complete fecal obstruction.

close approximation of the fixed ends of the sigmoid. (Fig. 2). Sigmoidoscopy here showed that the rectum turned markedly to the left at its upper end and at about eight inches from the anus the

instrument impinged upon the blank gut wall. By the aid of a long flexible bougie passed through the sigmoidoscope, I was able to pass the latter into a large distended sigmoid, which extended almost up

FIG. 1. Acute flexure of the sigmoid, due to too close apposition of its fixed points with long mesentery to its intervening loop, this loop protruding into the pelvis.

to the diaphragm, and contained many balls of hard, mucus coated feces.

In another supposedly congenital case the rectum turned just as markedly to the right, and I was unable to pass the sigmoidoscope beyond the flexure. Operation here revealed the sigmoid attached to the right side of the pelvis, where it is so often found in infancy, by a short mesentery and bending sharply back along the promontory of the sacrum to join the descending colon.

I do not mean to assert that all the cases with such symptoms as these are afflicted with acute flexure; but I do believe that the large majority of them owe their poor health and lack of development to fecal stasis and autotoxæmia. Procidencia, or as Gant calls it "chronic invagination," of the sigmoid into the rectum, or any other condition which prevents the bowel from emptying itself thoroughly and sufficiently often may bring them about; but the possibility of acute flexure should always be borne in mind in making the diagnosis.

In the acquired angulations there is usually, in addition to the constipation and distended cecum, a history of dysentery, typhoid, acute colitis, sigmoiditis, pelvic peritonitis, or inflammation of the pelvic organs. Following these, sometimes at long intervals, increasing constipation or irregularity of bowel movements appear with crises of colic, with nausea and vomiting, followed or not by passage of mucus; in some the symptoms are so severe that volvulus is suspected. In the majority, however, they are not so violent. The patients are constipated, muddy complexioned, have furred tongues, flatulence, bilious attacks, and pass more or less

mucus with their stools. The latter is often the most disturbing symptom. Examination may or may not show hemorrhoids, hypertrophy of Houston's folds, or other disease of the rectum; but it always shows, if there is an acute flexure, some point in the sigmoid in which the instrument instead of passing upward into the calibre of the gut comes squarely against the wall; atmospheric pressure nor pneumatic inflation neither open the gut in front of the instrument, and twist it about as we will, we cannot get the tube past this point. Sometimes by pressing as firmly as one dares to one side or the other, or downwards and forwards, we may pass the obstructing fold only to come squarely against the wall of the other leg of the flexure, or getting past, may lift up and stretch the binding adhesion or short mesentery so as to carry the instrument higher up; but this is a dangerous experiment; rupture of either the mesentery or adhesion, or of the gut wall would prove disastrous. Sometimes the mucous membrane prolapses through the narrowed calibre, looking like a prolapse, or, as Laroque says, like a sessile growth. Often there is abrasion or ulceration at the angulation. Another symptom of which many complain is incomplete evacuation. They may go to stool four or five times to pass what amounts to an ordinary stool. This does not vary between hard and soft stools. They even have to go several times to relieve themselves of a high enema. I have often made a provisional diagnosis upon this symptom occurring after an enema given in my office.

#### Treatment.

The treatment of these cases is both palliative and radical. In some instances of the acquired type I

FIG. 2. Acute flexure of the sigmoid, due to too close apposition of its fixed points with long mesentery to its intervening loop, this loop protruding into the pelvis.

have been able to give great relief and to get by pneumatic inflation, inflating long enough to pass through the flexure and leaving them inserted for fifteen to twenty minutes. The basis of this is that

the bougie in its tendency to straighten itself gradually stretches the binding tissues and thus straightens the flexure. The bougie should never be passed alone, however. The sigmoidoscope should first be

FIG. 5.—Acute flexure of the sigmoid, due to too close apposition of its fixed points with long mesentery to its intervening loop. The flexure at both its points is occasioned by accumulation of gas and lifting up of the long loop into the abdominal cavity.

passed up to the flexure, and the bougie passed up through this. Only in this way can we be sure that the flexible instrument passes beyond the angulation and does not double on itself. Before the bougie is removed there should be injected through it an oil or watery enema to wash out the bowel thoroughly. No doubt some will say that much of the relief given my patients has been due to these injections. In reply I can only say they had all tried injections and lavage before they consulted me. In some cases the inflation alone and applications to abraded or ulcerating surfaces have given relief. When such palliative measures fail, however, or where the condition is clearly due to malformations or firm fixation, operative interference should be resorted to at once. The operation, however, varies in each individual case. In some it is sufficient to break up the adhesions, cover up the raw surfaces, and turn the sigmoid loose, while in others it is necessary to fix the sigmoid to the abdominal wall and thus prevent the flexure from recurring. In general one may say *straighten out the flexures, cover in the raw surfaces, and if necessary fix the bowel so it cannot resume its old position.* How to accomplish these ends can best be shown by exhibiting the drawings and giving the details of some of my cases.

#### Case Histories.

*Case I.*—The sigmoid flexure of the sigmoid to the vertebral column; the descending and transverse colon (Fig. 6) shows a marked series of adhesions of the sigmoid, with acute flexures at its junction with the descending colon and at its adhesion to the transverse colon.

This specimen was found at an autopsy, and I could gain no history of the case. It simply shows to what extent the

sigmoid may rise and at what various points it may become adherent; it also illustrates how easily one may produce a flexure at the junction of the descending colon by suturing the sigmoid too high in the abdominal cavity.

*CASE II.*—Acute flexure of the sigmoid with obstipation from adhesions between two appendices epiploicae.

Mrs. M., age thirty-five, consulted me on November 20, 1895. Family history was negative. She had suffered from peritonitis two years previous; for some months had suffered from obstinate constipation, with crises of acute pain; abdominal distention, nausea, and vomiting; had been losing flesh and unable to eat an adequate amount of solid food; flatulence over descending colon and left iliac region, with some tenderness at this joint; decided dulness to the right of the medium line and three inches below the umbilicus. Temperature 100° F., pulse 110. Enemas had been used, only giving partial relief. The proctoscope showed nothing abnormal in the rectum, but the tube was arrested in the second loop of the sigmoid, about eight inches from the anus, by a sharp bend and apparent contraction in calibre; mucous membrane protruded through the narrowing, simulating a prolapse.

Operation was performed on November 23, 1895. Incision in medium line, peritonæum somewhat thickened; sigmoid flexure was found well up in the abdominal cavity and adherent to the abdominal peritonæum just to the right of the medium line. Dragging it out of the wound, two granulæ epiploicae were found united together by strong adhesions, thus folding the gut at a very acute angle. (Fig. 2.) The obstruction, however, did not seem to be at the flexure, but at the point of attachment of the two epiploicae. The descending colon was distended by a large amount of semi-solid fecal matter; the gut below the appendices was collapsed; the appendices were tied off at their base, some very slight adhesions between the two legs of the flexure were broken up, and then, by slight pressure, the fecal matter could be moved along into the cavity of the rectum. In the wall of the gut there were myriads of little lumps about the size of goose shot; they did not seem to protrude, however, upon the peritoneal surface; probably they were inflamed follicles; there was no evidence of diverticulae. The gut was carried back upon the left side to its normal position and the abdomen closed. Eight hours after the

FIG. 6.—Acute flexure of the sigmoid upon the right side, with chronic appendicitis and adhesion. Short mesentery.

operation the patient had a large semisolid movement, from the rectum. Convalescence was uneventful; bowels were washed out daily with high enemas, and laxatives administered as the occasion required. The patient was seen six years later; she had gained thirty pounds in weight, and

the bowels move regularly without medicine, although she occasionally had a little mucus in the stool; she had had no more crises, and considered herself perfectly well.

CASE III.—Acute flexure with prolapse, due to too close apposition of the two fixed ends of the sigmoid, with a long mesentery of the intervening loop.

Miss F., age twenty years, consulted me on March 10,

FIG. 7.—Acute flexure of the sigmoid upon the rectum, due to short mesentery and old pelvic adhesion.

1898. Family and personal history clear. German by birth. She had suffered from constipation ever since she was a child; was pale and anæmic, with periodical attacks of gripping pain, followed by diarrhœa; at times her abdomen swelled up very large and went down when gas was passed. The chief pain seemed to be in the left side and low down; during these attacks there was aching and a feeling of weight in the back; she said that sometimes when she went to stool she felt like the whole bottom of her pelvis was dropping out; there was no prolapse, but the anterior wall of the rectum bulged backward into the centre of the sacrum when lying upon her back or side. Hard fecal lumps were easily distinguished with the finger in Douglas's cul-de-sac. The lumps disappeared and the rectum ballooned easily under atmospheric pressure. The valves were highly hypertrophied, but no fecal matter rests above them. The sigmoidoscope was arrested at about the end of the first loop of the sigmoid by a valviform fold jutting out into the calibre; when this was passed to one side the instrument could be carried a little farther, where it came in contact with a large mass of hard fecal matter. Hydrogen peroxide, one half ounce, was introduced through the tube.

The patient passed some quantity of fecal matter, and some lumps since introducing peroxide. The weight in the back seemed less; no lumps could be felt by the finger in Douglas's cul-de-sac. The sigmoidoscope showed a complete circle of mucous membrane sitting through the aperture of the rectum with the sigmoid, which was bright red and congested. Under pneumatic pressure this disappeared, and with some manipulation the peritoneum could be carried upward to a distance of nine inches, although there was a decided pain in the back, and in the left side.

Diagnosis: Prolapse of the third degree, with contraction of adhesions to the anterior field of the sigmoid.

Operation was performed on March 18, 1908. Abdomen was opened to the left of the median line, through the rectus muscle. Sigmoid was found prolapsed in Douglas's cul-de-sac, the loop with the long mesocolon falling in front between the two fixed ends, and carrying two flexures, one at the distal and one at the proximal portion, as shown in Fig. 4. It could be easily lifted up, and upon doing so the

proximal flexure was obliterated; the distal, however, remained more or less acute on account of the very short mesentery and some slight adhesions to the walls of the sacrum. The adhesions were broken up, and the peritoneum of the mesentery incised so that the flexure could be straightened out. In this case it seemed almost impossible to draw the peritoneum together, and there was some raw surface left. The sigmoid was sutured to the transversalis fascia of the anterior abdominal wall to the extent of two and a half inches, running outward and upward with tension enough on the lower segment to hold the acute flexure straight; and with no tension on the proximal loop, in order to avoid a flexure at the junction with the descending colon.

Without going into detail, I may say that this patient suffered from some traumatic peritonitis, but was never in any danger of her life. She recovered in about six weeks; her bowels moved well enough after the acute inflammation had passed, and I was able to pass the sigmoidoscope to the extent of ten inches without any difficulty or pain. Practically all her symptoms disappeared, and for five years her health improved steadily; after this I lost sight of her.

CASE IV.—Another case of this type is shown in Fig. 4. This patient suffered with acute attacks of intestinal obstruction, with great pain in the left iliac region, but none in the back. The sigmoidoscope could be introduced its full length without obstruction, or any evidence of disease.

Operation here showed the same close apposition of the fixed ends with the long intervening mesentery; the sigmoid prolapsed down into the left pelvis, making a sort of twist or fold just below its junction with the descending colon. There were no adhesions and no narrowing of the gut that could be made out, and yet, when the gut was dropped back into the pelvis the twist or flexure immediately recurred. The sigmoid was fastened to the abdominal wall, nearly at the centre and almost up to the umbilicus, with more tension on the proximal loop than on the distal. There were no complications, and the crises of pain and obstruction have never recurred.

CASE V.—Mrs. M., age forty-seven, consulted me on January 1, 1905. Family history was clear. Patient had had malaria in early life; constipated since childhood; early

FIG. 4.—Acute flexure to the upper loop of the sigmoid, in part of a case of constipation, due to short mesentery and old pelvic adhesion. (Dr. Weyden, 1904.)

and irregular menstruation; complexion never clear. She complained of pain in the left iliac region, and at times of acute obstruction, but no pain in the back. The sigmoidoscope was introduced to the full length without obstruction, or any evidence of disease. Operation here showed the same close apposition of the fixed ends with the long intervening mesentery; the sigmoid prolapsed down into the left pelvis, making a sort of twist or fold just below its junction with the descending colon. There were no adhesions and no narrowing of the gut that could be made out, and yet, when the gut was dropped back into the pelvis the twist or flexure immediately recurred. The sigmoid was fastened to the abdominal wall, nearly at the centre and almost up to the umbilicus, with more tension on the proximal loop than on the distal. There were no complications, and the crises of pain and obstruction have never recurred.

region; pain on deep pressure in right inguinal region and also on taking a large enema, two or three attempts were necessary to relieve her of the fluid; a small tender mass could be felt through the vagina and abdominal wall just below the promontory of the sacrum; it did not feel like the ovary or tube; she occasionally lost blood at stool. Examination showed small internal hemorrhoid, spasmodic sphincter, and obstruction apparently due to an acute flexure at the right sacroiliac junction. No ulceration could be seen and there was no evidence of growth.

Operation was performed on January 28, 1905. An incision was made just outside the right rectus muscle, the small intestine being lifted up out of the pelvis; the sigmoid flexure at its junction with the rectum was found to bend sharply over to the right of the pelvis, where it was held by adhesions to the sacrum; the appendix passed down over the brim of the pelvis and was adherent to the convex surface of the sigmoid; it was thickened and contracted at one or two points and contained three small faecal stones; this organ being released from its adhesions was extirpated, the adhesions of the sigmoid broken up, and the gut lifted up into the abdominal cavity, thus straightening the flexure on the rectum, as well as at its first and second folds. The

FIG. 1.—Gastroenterostomy with descent of the transverse colon, acute angulation at the splenic flexure, together with adhesion and angulation of the sigmoid flexure, due to old tubal and ovarian inflammation.

sigmoid was sutured to the abdominal wall, the suture embracing one inch above and one inch below the point of flexure, thus holding this part of the gut straight out against the abdominal wall. The abdomen was then closed, hemorrhoids removed, and the patient removed to her room.

February 15th. Convalescence was uneventful; bowels moved without pain in the sigmoidal region by oil enemata; the usual amount of pain at the field of hemorrhoidal operation.

February 20th. Convalescence was uneventful until today. Dermatitis or erythema developed about the rectum, simulating erysipelas. So far as constipation and pain in the right side were concerned the patient never had another complaint, and is to-day having regular movements of the bowels without laxatives; her digestion is perfect. The erythema spread from the buttocks and anal region all over the body. Temperature was as high as 105° F. and never below 102° F. for three weeks. Numerous consultations with specialists revealed no actual cause or pathology for the same; blood examination showed no streptococcus and no marked increase in leucocytes. We were forced to con-

tent ourselves with an uncertain diagnosis of obscure toxæmia, which gradually wore itself out or was cured through diet and intestinal antiseptics.

CASE VI.—Acute flexure due to shortened mesosigmoid.

Miss D., age seventeen, consulted me on October 25, 1902. Patient was pale, anæmic, of dull complexion; had suffered all her life from constipation and dyspepsia; menstruation irregular; she had never grown as other children, weight only seventy-eight pounds. Abdomen was rather distended; marked tympanic notes over cæcum; dulness over left iliac region; on palpation one could feel a nodule mass extending from the median line out to the crest of the ilium. Rectal examination showed nothing abnormal; the sigmoidoscope was arrested just beyond the rectosigmoidal junction, the cavity of the gut could be seen dipping down forward into Douglas's cul-de-sac; but the sigmoid could not be inflated or lifted up so as to introduce the tube. A long soft rectal tube was introduced through the sigmoidoscope, and by the aid of a stream of water this was carried up into the sigmoid. It was covered with faecal matter and mucus when withdrawn; this examination and injection was followed by a large discharge of faecal matter. The bowel was again washed out in the same manner as before, and with a large return of faecal material. Examination afterward showed practically normal resonance over the left iliac region; palpation, however, showed a thickened sausage shaped tumor extending from the median line over to the sacroiliac junction.

Diagnosis: Congenital stricture or malformation of the sigmoid, with possible neoplasm.

Operation was performed on October 27, 1902. Abdomen was opened to the left of the rectus muscle; sigmoid found in the upper pelvis, very thick and inelastic, but not adherent at this point; it dipped down into Douglas's cul-de-sac, and just at the left of the rectum it was found by a mesentery which held it almost against the sacral wall, thus causing an acute flexure with the rectum and also with the loop above. Any dragging upon the upper loop of the sigmoid increased the flexure; it was impossible to lift this up without increasing the flexure. The danger of cutting the bloodvessels and destroying circulation by incising the mesentery through and through was apparent. In order to overcome the flexure and stricture I made a longitudinal incision in the peritonæum extending about one inch to either side of the flexure; this was done on the right and left, the cellular tissue not being involved. I was then able to lift the gut up and unfold the flexure, breaking up the adhesions between the first loop of the sigmoid and the rectum. The peritoneal wound was sutured transversely, thus lengthening the mesentery, so that the flexure was almost obliterated. The second loop of the sigmoid was then drawn up and attached to the abdominal wall, thus straightening out the flexure and holding it in this position. The abdominal wound was closed.

November 10, 1903. The patient suffered from severe dragging pain for about a week; in the mean time, her bowels were washed out daily with 1 in 500 carbolic solution. After this time she began to improve; her digestion became much better, and her bowels acted freely with small doses of cascara. I have heard from her within the last ten days; her bowels now act without medicine, and she has gained nearly forty pounds; she is teaching school, and is a very grateful patient.

This case is very instructive, showing the futility of simply drawing the sigmoid up in such cases of acute angulation. Had the sigmoid been drawn up without loosening it at the point of angulation, the flexure would have been increased, the faecal obstruction made worse, and the patient would probably have suffered from acute obstruction of the bowels.

CASE VII.—Fæcal stasis with acute flexure of the middle loop of the sigmoid.

Mr. F., age forty-two, of pale, flabby, anæmic appearance. Family and personal history clear. Patient had suffered from constipation for five years; this came on after an attack of acute inflammation of the bowels, which followed a long bicycle ride. Tympanites over the head of the cæcum; more or less distention of the transverse and descending colon; flatulence in the left iliac region. Local examination showed the anus and rectum normal. The tube

passed readily into the sigmoid, but it had to be directed forward to the left; at about eight and a half inches it was arrested by coming squarely against the wall of the gut. Inflation did not lift up the sigmoid, but by carrying the tube as much forward as possible a glimpse of the opening through the flexure could be obtained, with a mass of hard faeces pouting through the same.

December 5, 1906. Operation revealed an acute flexure of the sigmoid, with adhesions over the left iliacus muscle low down (Fig. 7). The adhesions were incised, raw surface closed in, and the pelvis filled with saline solution. As soon as the adhesions were broken up the sigmoid rose so easily into position that it was not thought necessary to suture the gut to the abdominal wall. A long Wales bougie was passed into the rectum daily, beginning three days after the operation. The constipation and other symptoms disappeared very rapidly.

CASE VIII.—Mr. G., age forty-four, referred by Dr. John A. Wyeth, on March 24, 1906. Patient had been operated upon for hemorrhoids five years previously and had his sphincter stretched, with a view of overcoming obstinate constipation. So far as the relief of this symptom was concerned the operation was ineffectual. Constipation had been aggressive, and it was now almost impossible to obtain a movement of the bowels with any amount of laxatives; he complained of desire to go to stool, but inability to have a satisfactory movement; had a bearing down pain in the left inguinal region, extending upward to the splenic flexure; dulness over ascending colon; markedly tympanitic note over the cæcum. Proctoscope passed seven inches into the sigmoid, beyond which I was unable to advance on account of an acute flexure, with probable adhesions, as the sigmoid could not be lifted up into the abdomen.

Patient was operated upon on March 31st by Dr. Wyeth. The second loop of the sigmoid was found adherent over the iliacus muscle just above the brim of the pelvis; thus forming an acute flexure or angulation, with a mechanical constriction of the calibre (Fig. 8); there was no cicatricial narrowing of the canal. As soon as the adhesion was divided the constriction was relieved. The raw surface left by this division was closed over, both on the gut and abdominal wall, and the sigmoid lifted well up into the abdomen. No attempt was made to fix the gut, as this seemed unnecessary. The patient made an uneventful recovery, and his constipation disappeared in about three weeks.

CASE IX.—Mrs. L., age thirty-five, had suffered for years from constipation, flatulence, and hemorrhoids. Hereditary antecedents were negative. Digestive disturbance came on three or four hours after eating; bowels never moved without a large laxative; she had had an attack of pelvic peritonitis with salpingitis some six or seven years ago. Physical examination showed distended cæcum and transverse colon; stomach had prolapsed one inch below the umbilicus, and the transverse colon dipped down almost to the pubes.

Operation revealed general gastroenteroptosis with the transverse colon and omentum prolapsed into the pelvis, the omentum being adherent; there was considerable distention of the transverse colon; the sigmoid in its second loop was adherent to an old indurated tube; an acute angulation of the gut at the splenic flexure, also in the sigmoid, but not so marked as above (Fig. 9). The adhesions of the omentum to the sigmoid were incised and the raw surface of the latter closed by sutures. The stomach and transverse colon were lifted up, and the omentum sutured across the abdominal wall one inch above the umbilicus, thus relieving the angulation at the splenic flexure. The sigmoid was turned loose and lifted up into the abdomen, but not sutured. The pelvis was filled with saline solution, and the abdominal wound closed.

This patient made an uneventful recovery, improved in health and bowel movements, but some months, at which time she was in the country, and after eating a lot of green fruit and other raw food, was seized with an acute attack of enteritis, which lasted several weeks. At this time she also had a recurrence of salpingitis, and there now appeared to be a readhesion of the sigmoid in the neighborhood of the left ovary. The transverse colon, however, remained in position and there was no more of the pain in the left side and much less flatulence and digestive disturbance than formerly.

It would probably have been wise to have fixed the sigmoid to the abdominal wall at the first operation, but I was struck by the gut at so many points, that I could not attempt to fix the sigmoid in any one place.

the present time much relief, and it is possible an operation for the new adhesion may be avoided.

CASE X.—On December 6, 1904, Mrs. R., age thirty-five, consulted me. She had two children. Complexion clear, in fairly good flesh. Family history negative. Had a severe attack of dysentery at nine years of age, otherwise no serious illness. After the birth of first child she had suffered from childbed fever; following this had nervous trouble, with flashes of heat, violent headaches, and increasing constipation. Now suffered from severe constipation, hard, lumpy stools; weight and pain in the left iliac region; very slight tenderness over the appendix; much flatulence and digestive disturbance; pain in the left side was increased by stool. Examination of the rectum showed nothing abnormal; the sigmoidoscope passed into the sigmoid without difficulty; tube deflected markedly to the left, at about three inches, the upper wall of the gut impinged upon the instrument and even with pneumatic dilatation it was difficult to pass the instrument farther on account of pain in the left side, although there seemed to be no diminution of the calibre.

Diagnosis: Adhesions of the sigmoid to the left tube and ovary.

Treatment: Hot douches, introduction of a Wales

Fig. 9. Acute flexure of the sigmoid colon, chronic salpingitis and multiple fibroids of the uterus.

bougie every other day, with a hope of stretching out the adhesions and allowing the bowels to move freely. This treatment was carried out by the physician in attendance.

1905. The patient was improved by the treatment somewhat, but returned still suffering more or less from the same condition and was made so nervous by the treatment that she asked for radical relief. An operation was therefore performed in June, 1905. The abdomen opened in the median line; appendix drawn out, and being found abnormally enlarged, was removed. The sigmoid was found closely adherent to the left tube, ovary, and broad ligament, causing quite an acute flexure when the proximal loops were lifted up. The adhesions were dissected off, and the raw surface in the pelvis covered as well as possible by suturing; the sigmoid was drawn up into the abdomen, and the loop which had been adherent down below was sutured to the transversalis fascia to the extent of about two inches, thus straightening out the flexure.

The abdominal wound was then closed. There followed uneventful recovery. The patient has been healthy since, suffering with no return of the old trouble, and in the third year after the operation still well. On the 1st, 1906, patient reported herself entirely well.

CASE XI.—Miss McG., age forty-four, very thin, of

muddy complexion. Family history negative. Twelve years ago patient had had an attack of intense pain over the lower abdomen, with high temperature. Pain and irritation continued more or less all summer; after this constipation had always been present. Eight years ago she had a severe pain in the abdomen, with fainting spell, which was followed shortly by a passage of a large mucous cast. Since this time she had had periodical mucous crises, passing mucus all the time; required enemata usually to induce a movement. There was present tenderness over right iliac fossa; on deep pressure distention of the cæcum and ascending colon; anus was normal; rectum somewhat congested; sigmoid tender upon touch, turned sharply to the right and could not be lifted up, acute flexure at about six inches from the anus, thick cord like mass could be felt with the finger high up in the rectum and running upward toward the cæcum.

Diagnosis: Inflamed appendix in the pelvis.

Patient was operated upon on January 30, 1908. Appendix enlarged to the size of one's little finger, very tortuous and running down the iliosacral line almost into Douglas's cul-de-sac. The sigmoid was attached to its tip and held firmly in the pelvis, acutely flexed at the point of attachment. At the angulation of the appendix the ileum was caught and adherent, thus producing an acute flexure of this organ (Fig. 10). The sigmoid was released, as was also the ileum, and straightened out by breaking up the adhesions. The appendix was then freed and removed; the raw surface covered up as well as possible by sutures. The object to which the sigmoid had been adherent having been removed and its raw surface covered up, it was not thought necessary to suture the gut to the abdominal wall.

At the present writing, three weeks after the operation, the patient is apparently perfectly well; her bowels move without enemata; digestive symptoms have disappeared, and mucus in the stool is no longer seen.

These cases represent some types of flexure or angulation such as may be found in the sigmoid and transverse colon. The methods of dealing with them have been largely justified by the results; but no doubt some of my readers will devise different and better technic in the future. I should now with wider experience proceed differently with some myself; but working along original lines one cannot always select the most direct and smoothest paths. I have reported the cases with as little detail, but as accurately as possible, and trust they may excite a wider study of this interesting condition.

42 WEST FIFTIETH STREET.

## THE DIAGNOSIS OF DISEASES OF THE HEART.\*

By WILLIAM HENRY PORTER, M. D.,  
New York,

Professor of Pathology and General Medicine at the New York Postgraduate Medical School and Hospital; Attending Physician to the New York Postgraduate Hospital, etc.

The subject which you have asked me to discuss at this meeting is a very large one; and one the elucidation of which, in the time at my disposal, will be most incomplete. Therefore, the most that can be accomplished will be a very brief consideration of a few of the most important points and questions in diagnosis that we are called upon to decide almost daily.

One of the most important points to be considered in connection with the diagnosis of cardiac affections is, how to recognize and correctly interpret the so called valvular murmurs. This is especially true in view of the fact that we have well defined murmurs, when there is no endocardial lesion of the

valves, and where at the necropsy all the valves are found to be practically normal.

In order to accurately diagnosticate these valvular affections of the heart, it is absolutely essential to understand precisely the anatomical position of the organ, and also the physiological mechanism of the action of the heart. This is especially true of those murmurs that are located at the left auriculoventricular orifice when there is no organic lesion of the valve segments.

If, as is usually the case, the anatomical position of the heart is taken from frozen sections of the body, it will appear to be located upon a lower plane than actually occurs during life, hence great errors in diagnosis are easily made unless due cognizance is taken of this fact. During life the heart cavities and the great blood vessels are distended with blood, which naturally causes the viscera to occupy a higher position in the chest than is the case when empty in death. While the individual is alive, therefore, the long axis of the heart occupies a triple oblique position in the chest cavity, or one corresponding to a line drawn from right to left, from above downward, and from behind forward—a position that has for its central axis a line represented by one transfixing the body from behind forward, starting posteriorly, at the sixth dorsal vertebra, passing through it and the cavity of the chest and emerging on the anterior surface of the thorax, through the fifth intercostal space 1.34 centimetres (3.5 inches) from the midsternal line.

The base of the heart corresponds to a line drawn obliquely across the anterior surface of the chest wall, from the first intercostal space on the left side to the second intercostal space on the right side. The apex of the heart is located just within the anterior or chest wall, behind the fifth intercostal space of the left side, at its junction with the sixth rib, 1.34 centimetres (3.5 inches) from the midsternal line.

The left heart is the most posterior; this is especially true of the left auricle, which is also the most inferior portion of the organ, as it lies deep down in the space between the vertebra and diaphragm. As a result of this posterior and inferior position of the cavity of the left auricle, the current of blood discharged from it into the left ventricle naturally flows from behind forward, from right to left, and slightly from below upward, or directly across the chest cavity, but never from above downward. The direction of this current corresponds to the line already given, as transfixing the body, and to which, many years ago, I gave the name left auriculoventricular axis. From this description it is clearly apparent that the bicuspid or mitral valve is located well to the posterior limit of this left auriculoventricular axial line. All murmurs, therefore, that occur at the mitral orifice are produced and transmitted by the current of blood flowing in one or the other direction of this axis.

When studying these conditions, we should always remember that a common law governs the seat of production and transmission of all cardiac murmurs, to wit, that the abnormal sound called a murmur is heard with greatest intensity just beyond the point of its development, and that the sound is

\*Read before the Medical Association of the Greater City of New York at a special meeting held in the Bronx, January 6, 1908.

transmitted from the point of its production forward or backward in the direction of the current of blood which, together with the valvular defect, is the cause of the murmur.

Where there is an organic narrowing of the bi-

FIG. 1.—Professor Porter's skeleton scheme, showing position of the heart in the chest cavity; also circular areas at which points the different murmurs can be heard with greatest intensity. The arrows indicate the direction in which the murmurs are transmitted. Ring MD, a mitral, direct, aortic, stenotic, or presystolic murmur at the mitral orifice. Ring AD, an aortic, direct, stenotic, or systolic murmur at the base of the heart. Ring AI, an aortic, indirect, regurgitant, or diastolic murmur at the base of the heart.

cuspid orifice an abnormal sound is produced in the line of this left auriculoventricular axis, by an obstruction to the normal incoming current of blood from the left auricle to the left ventricle. This murmur has often been called presystolic, which is true so far as the ventricle is concerned, but in reality it is a systolic murmur of the left auricle. It occurs at the height of or just at the end of the auricular contraction and just as the ventricle is beginning to contract. If, for any reason, the auricular and ventricular power becomes enfeebled, so that there is no counter resistance in the currents of blood, the murmur often entirely disappears; the same is true if the auricle alone becomes very much enfeebled. In both instances with a resumption of muscular power the murmur will be reestablished.

A mitral direct murmur is heard with greatest intensity just in front of and over the left ventricle, at a point where the left auriculoventricular axis strikes the anterior surface of the chest wall, over the insertion of the fourth rib and its adjoining costal cartilage, or within the ring marked MD, in Figs. 1 and 2. This murmur is, as a rule, high pitched, of short duration, and limited in area. The intensity of the murmur will vary with the degree

of obstruction and the strength of the auricular contraction.

An obstructive murmur, located at the left auriculoventricular orifice, without alteration in the structure of the segments of the mitral valve, is not unfrequently heard in connection with considerable leakage at the aortic orifice. The explanation for this murmur is that the rapidly regurgitated blood from the aorta into the left ventricle fills the apical portion of the left ventricular cavity, and by so doing crowds one segment or the other of the bicuspid valve quickly against the incoming current of blood from the left auricle and thus, for the time being, produces an obstruction to the incoming current of blood. This undue pressure of the segments of the valve toward the auricular cavity at the height of the auricular contraction gives rise to a short but quick, sharp, and decided obstructive murmur. This murmur is distinguished from one due to positive organic narrowing at this orifice by its frequent disappearance when the physiological action of the heart, acting as a mechanical pump, is improved, so that the regurgitation of blood from the aorta back into the left ventricle becomes very much less, so much so that the valve is not pushed up against the incoming current of blood from the auricle.

When there is an organic incompetency at the left auriculoventricular orifice, the abnormal sound or murmur is produced by the blood being forced back into the auricle by the contraction of the left ventricle at the time of its systole, the blood being forced into the auricle against the incoming current of blood; the murmur in all probability being produced by the opposing currents having an unequal pressure against each other. The murmur is produced by the current of blood that is running from left to right, from before backward, and slightly from above downward. This murmur is distinctly heard at the apex region or within the circle lettered MI in Figs. 1 and 3. It is transmitted to the left and is, as a rule, lost at the anterior axillary line, but it is heard posteriorly with equal intensity at a point midway between the inferior angle of the scapula and the eighth dorsal vertebra on the left side. According to the ordinary law governing the production and transmission of cardiac murmurs already given, this mitral indirect murmur should only be heard posteriorly; but occurring, as it does, at the same time of and as the result of the ventricular contraction, or when the heart becomes, as it were, a solid body, and impinges against the anterior bony chest wall, which is also a dense body, they together obey the general physical law of transmission of sound by dense bodies, and thus bring the abnormal sound or mitral indirect murmur distinctly to the anterior surface of the chest, so that it is heard most distinctly within the circle lettered MI in Figs. 1 and 3.

When I was a student in medicine it was commonly taught that a systolic murmur heard at the apex region, within the circle marked in the figures MI, and transmitted from this point to the left as far as the anterior axillary border, and heard behind, as already noted, always indicated an organic lesion of the mitral valve. This assertion, in the light of our ever advancing knowledge, is frequently found to be incorrect at the present day, and still more frequently it proves to be false at the bedside.

Therefore, a different interpretation has to be placed upon the murmur in many instances.

This regurgitation at the mitral orifice, without organic changes in the valve segments, unquestionably produces a mitral indirect murmur, and one which is of the greatest importance. *First*, because of its frequency; *second*, because it is so often mistaken for a sound due to positive organic changes in the valve segments. From this it is readily seen that it is not the leakage that is questioned, but the interpretation put upon the murmur. If we stop and consider for a moment the anatomicophysiological mechanism of the heart, acting as a pump, the explanation and diagnosis in this class of cases are quite simple. The ventricular wall of the heart is composed of seven distinct anatomical layers of muscle fibres, or for simplicity they may be considered as four. There are connected with these layers, in the left ventricle two sets of papillary muscles, one springing from the anterior and the other from the posterior wall of the ventricle. To these papil-

fect action just described, one set of muscles contracts more forcibly or more quickly than the other, and as a result one papillary muscle shortens more than the other. As a natural sequence, one segment of the valve is pulled a little too far into the ventricle, while the other segment of the valve floats too far out into the auricle, thus preventing complete closure of the mitral orifice and permitting an escape of blood from the ventricle to auricle. In this manner a complete gap is produced, the same as if there was an organic lesion. This is well illustrated in the schematic drawing as seen in Fig. 2, b.

Through this opening, which has resulted from the incomplete coaptation of the two segments, there is a positive escape of blood and one that gives rise to all the physical signs of an organic insufficiency with regurgitation. The temporary results are the same as if there existed positive and irreparable defects. The physical signs are the same in both instances.

This condition is very frequently diagnosed

FIG. 2. (a) Normal heart, showing perfect closure of the mitral valve, and normal aortic and pulmonary semilunar valve segments. (b) Functional diagram, showing imperfect closure of mitral valve, but without organic changes in the valve segments; also congenital perforations in the aortic semilunar segments. (c) Diagram illustrating the congenital perforations in the aortic and pulmonary semilunar segments.

lary muscles the segments of the bicuspid valve are attached by the corda tendineæ.

When everything is working in unison, the two segments of the bicuspid valve which are in the ventricular cavity float outward toward the auricular cavity. At the height of the ventricular contraction, the margins of the bicuspid segments are approximated at just the right point, and held there by the equal and synchronous contraction of the two sets of papillary muscles and their attached chordæ tendinæ (Fig. 2, a). By this peculiar mechanism the auriculoventricular orifice is perfectly closed, and regurgitation from the left ventricle to the auricle is prevented. When for any reason the innervation of the heart is unequally distributed to the different papillary muscles or the muscular layers become unequally nourished, the unity of contraction is apt to be disturbed, and, instead of this per-

fect action just described, one set of muscles contracts more forcibly or more quickly than the other, and as a result one papillary muscle shortens more than the other. As a natural sequence, one segment of the valve is pulled a little too far into the ventricle, while the other segment of the valve floats too far out into the auricle, thus preventing complete closure of the mitral orifice and permitting an escape of blood from the ventricle to auricle. In this manner a complete gap is produced, the same as if there was an organic lesion. This is well illustrated in the schematic drawing as seen in Fig. 2, b. Through this opening, which has resulted from the incomplete coaptation of the two segments, there is a positive escape of blood and one that gives rise to all the physical signs of an organic insufficiency with regurgitation. The temporary results are the same as if there existed positive and irreparable defects. The physical signs are the same in both instances. This condition is very frequently diagnosed

each case, for each case must be analyzed by itself. These cases are of great interest from a practical standpoint, both to the patient and practitioner.

Organic and the so called functional insufficiency at the left auriculoventricular orifice can easily be distinguished during life, not by their rational or physical signs, however, but by an appropriate line of treatment. If the cause of the so called functional murmur be a deficient innervation, by giving such remedies as will restore the nerve power, the signs and symptoms will quickly disappear, all regurgitation be prevented, and the patient relieved from all the unpleasant symptoms.

On the other hand, when due to defective nutrition, with incomplete innervation and irregular muscular action, a building up of the cardiac muscle, as can be done with proper diet and therapeutic remedial agents, will cause the murmur to disappear.

When the physical signs are due to positive lesions in the valve segments, then the physical signs will not disappear, but will usually become more pronounced under treatment, even though the general condition is improving.

Having settled accurately which of the two classes of murmurs we have to deal with, and having decided whether they are due to organic changes or not, if one has spent considerable time in the study of necropsy findings, it is easy to determine what the nature of the lesion is. Without a large experience, however, in the post mortem field, there is absolutely nothing upon which to rest the certainty of the diagnosis made. Unfortunately, however, too many of our profession are compelled to go through their whole medical career without ever having had much opportunity to get personal and practical training in this most important branch of medical science—the combined clinical and necropsy work. The more frequently one can be placed on record as to the diagnosis, and have it confirmed or overthrown by the result of the necropsy, the greater will be the skill in diagnosis.

If now, upon auscultation of our patient, we find within the circle or mitral indirect area, which is lettered MI in Figs. 1 and 3, instead of the normal first sound of the heart, that there is an abnormal blowing sound, there is present a mitral indirect or regurgitant murmur. Further, if we find that this sound is transmitted to the left along the fifth and sixth ribs, that it is lost as we approach the anterior axillary region, and that it is heard quite distinctly posteriorly, we are positive that regurgitation is occurring at this orifice. Under these conditions we are justified in saying that there is a leakage at the bicuspid orifice. We are not, however, justified in saying that there is an organic damage to the valve structures until we have had the patient under treatment for a reasonable space of time. Then by the disappearance or intensification of the murmur a positive diagnosis can be made.

When there is also a faint abnormal sound or direct mitral murmur heard with greatest intensity within the limited area or circle MD, as indicated in Figs. 1 and 3, and this sound or murmur is of very short duration and not transmitted, there is an obstruction to the incoming current of blood to the ventricle. Therefore, some difficulty may be experienced in detecting this murmur, as it is often masked to a cer-

tain degree by the aortic and mitral indirect murmurs. But if one listens intently there will be heard a distinct abnormal sound, which is distinctly limited to the circle lettered MD. If the chest piece of the stethoscope is moved outside this limited area, the murmur is at once entirely lost, and it is observed that its character is entirely different from the transmitted sound of the aortic or mitral murmur, with which it might at first be confounded. Thus we are enabled to decide that a certain amount of obstruction is offered to the current of blood as it flows from the left auricular cavity into that of the ventricle. As before stated, a course of treatment will enable us to distinguish between true obstruction or one due to overfilling of the ventricle secondary to aortic insufficiency.

There is also a double set of murmurs to be considered at the aortic valve as well as at the mitral. The abnormal sounds developed at this aortoven-tricular orifice are best divided into three general classes: *First*, those due to organic changes in the valve segments and the aorta, or in the substance of the ventricular wall as a whole; *second*, those due to congenital perforations of the segments of the aortic and pulmonary valve, and which may be classed as functional when compared with the truly organic changes that are acquired; and *third*, the so called hæmic murmurs.

At the aortoven-tricular aperture we have an axial line upon which all murmurs are developed and transmitted similar to that for the mitral. The direction of this axis is through the centre of the aortoven-tricular outlet from below upward, from left to right, and from before backward, following

FIG. 1.—Chart of patient with regurgitant at the mitral orifice, illustrating which of the physical signs are to be heard most distinctly, and as indicating the position of transmission of abnormal sound. Reg. MI, mitral indirect or regurgitant murmur, heard at base of heart; Reg. MD, mitral direct or obstructive murmur, heard at base of heart; Reg. AI, aortic indirect or hæmic murmur, heard at base of heart; Reg. AD, aortic direct or obstructive murmur, heard at base of heart; Reg. MI, mitral indirect or regurgitant murmur, heard at base of heart; Reg. MD, mitral direct or obstructive murmur, heard at base of heart; Reg. AI, aortic indirect or hæmic murmur, heard at base of heart; Reg. AD, aortic direct or obstructive murmur, heard at base of heart.

the natural course of the blood stream. All murmurs, therefore, which originate at the aortic valve must necessarily be produced by the current of blood flowing through the now abnormal opening, either in the direction of the normal blood stream, or at a right angle to a line drawn obliquely across the sternum opposite the third costal cartilage, as shown between the rings AD and AI in Figs. 1 and 3. The position of the aortic valve being posterior to the sternum very nearly behind the oblique bar as seen in the figures referred to, all abnormal sounds developed at this outlet will be due to an obstruction to the current of blood, as it is thrown from the left ventricular cavity through the aorta, or to a failure of the aortic valve to close tightly and prevent any leakage back into the ventricle, which must of necessity follow incomplete closure.

Having developed the lesion, obeying the common law of production and transmission of cardiac sounds, if there is a stenosis or obstruction to the current of blood as it normally leaves the ventricle to reach the aorta, a murmur will be produced and heard just beyond the seat of its development, which is at the aortic aperture, or in the second intercostal space on the right side at the sternal margin, as indicated by the circle lettered AD in Figs. 1 and 3. It is transmitted along the course of the great vessels, and is heard with almost equal intensity over the subclavian, and the common carotid arteries in the neck. When it is loud at the seat of development it will also be heard posteriorly where the aorta begins to impinge against the spinal column or over the fourth and fifth dorsal vertebra. In some rare instances it will be transmitted all the way down the spinal column, being heard as low down as the sacrum. On the other hand, if there is an incomplete closure of the aortic valve, the arterial tension forces some of the blood back into the ventricle, it causes an indirect or regurgitant murmur. This abnormal sound, according to the common law of production and transmission, is heard just below and to the left of the location of the aortic valve, or at the junction of the third intercostal space of the left side with the sternum, as indicated by the circle lettered AI in Figs. 1 and 3. The natural course of the transmission of this murmur is primarily governed by the direction of the blood stream which causes its production and would be downward and forward toward the apex. This is true in part, but, developed as it is, when the ventricle is expanding against the sternum, which is a dense structure, the common physical law of transmission of sound is obeyed, and the murmur is distinctly transmitted down the sternum, and is often heard with the same intensity over the xiphoid appendix as it is at the point of origin.

In the second variety, or those due to congenital perforations in the cusps of the aortic and pulmonary valves, there are often heard the same well defined physical signs, the same as occur in a well established case of aortic insufficiency due to more positive lesions, which produce incomplete closure of the aortic valve. I have frequently diagnosed these congenital perforations and later confirmed the correctness of the diagnosis at the necropsy. Aortic regurgitation from incomplete closure of the aortic valve can be distinguished from regurgitation due

to congenital perforations by observing the following distinctive points:

Aortic regurgitation from	
acquired lesions.	congenital perforations.
1. Physical signs almost the same except masked cardiac enlargement of the heart.	Physical signs almost the same except no uniform enlargement of the heart.
2. Marked subclavian pulsation.	No subclavian pulsation.
3. Shot or bead like pulse.	Pulse normal.
4. Marked dyspnea.	No dyspnea.
5. Cardiac interstitial pneumonia.	No brown induration of the lung.
6. May have pulmonary hemorrhages.	No pulmonary hemorrhages.
7. Cough with considerable sputum.	No cough or sputum.
8. Dropsy usually marked.	No dropsy.
9. Great general discomfort.	No general discomfort.
10. Physical signs may change under treatment.	Not affected by treatment.

In consequence of these facts a positive diagnosis in cardiac lesions should only be given after several examinations and after suitable treatment has been instituted.

Third, so called hæmic murmurs are produced at the aortic and mitral orifice in very anæmic subjects; they may be of the direct or indirect variety. A direct murmur may be produced both at the mitral and aortic orifice in very anæmic cases. More frequently, however, there is an incomplete closure of the mitral valve and an indirect murmur is heard, which is due to a dilatation of the ventricle brought about as a result of the anæmia and imperfect nourishment of the muscular structures. The hæmic murmurs will be heard and transmitted in the same manner as the murmurs already described as occurring at the mitral and aortic orifices. They are distinguished from the other forms of murmurs by the associated anæmia, and the rapid disappearance of the murmur under suitable treatment.

In this discussion the right side of the heart will be largely omitted. The reason for this is, that during a period of more than twelve years of almost continuous work in the dead house, during which time I made and observed a very large number of necropsies, only one case was met with in which there was a primary lesion of the valves of the right side of the heart, and that was a case of congenital incompetency of the pulmonary valve. This statement refers to cases of a chronic nature, and not to the acute infective or malignant type. During the life of this patient just referred to, although examined very carefully by several noted and exceedingly competent diagnosticians, all regarded the case as one in which the lesion was primary in the aortic valve, with secondary changes on the right side of the heart. Whereas, the aortic valve was found at the necropsy to be perfectly normal. Pulmonary and tricuspid leakage always gives rise to marked jugular pulsation which is synchronous with the systolic action of the ventricles. When this occurs there is also an associated general venous engorgement. Therefore, it is easy to say that there is leakage on the right side, but almost impossible to say that it is primarily located on the right side, and that it is not secondary to changes of the left side.

A tricuspid direct or indirect murmur is practically an impossibility, owing to the almost negative blood pressure on both sides of the valve. A leakage may occur at the tricuspid valve as a secondary sequence to a pronounced mitral and pulmonary insufficiency, but never as a primary condition so long

as the pulmonary valve closes perfectly. We are, therefore, justified in omitting the right side of the heart from the diagnosis of primary affections of this organ, except in those cases in which there is an infective or malignant endocarditis.

The murmur, which is often described as a tricuspid regurgitation during life, is usually found at the necropsy to be due to a leakage of blood through congenitally perforated aortic and pulmonary cusps. According to the general law of development and transmission of murmurs, if a tricuspid indirect murmur is to be heard, it would be posteriorly and not anteriorly, because at the time of its production the right heart is rolling away from the anterior wall of the chest, which would tend to carry the sound back into the chest rather than to bring it forward to the anterior surface of the chest. Therefore, it seems reasonable to exclude murmurs of the right side of the heart from this discussion, for they are of little practical value to the diagnostician.

Enlargement of the heart, either as the result of hypertrophy or degeneration with dilatation, is determined by an increased area of dulness on auscultatory percussion. The hypertrophy from degeneration is determined by auscultation and a careful study of the muscular tone. If the muscular contraction is firm and strong we know that there is a hypertrophic condition of the organ. If, on the other hand, the muscular contraction is soft and feeble, we know that there is an atrophic or decided degenerative change in the muscular tunic of the heart.

A careful determination of the nutritive tone of the heart muscle is one of the most important facts to be ascertained in connection with the diagnosis of cardiac disease, because upon it depends the prognosis not only in purely cardiac affections but also in all the infectious diseases.

1674 BROADWAY.

#### INDICANURIA: ÆTIOLOGY, DIAGNOSIS, PATHOGENY, AND TREATMENT.\*

BY GEORGE M. MACKEE, M. D.,  
New York.

Clinical Instructor of Dermatology at the New York University and  
Bellevue Hospital Medical College.

The demonstration of blue coloring matter in the urine has been recorded as far back as the time of Hippocrates (1), but it was not until 1840 when Prout (2) discovered a blue substance in the urine, to which he gave the name of indigo, that much attention was directed to the subject. For a considerable period this substance was thought to be identical with the indigo of plant life, which, according to Bartley (3) is a glucoside, but in 1879 Baumann and Breiger (4) proved that urinary indican was a combination of a conjugate sulphur of a hydroxylated indol with an alkali.

In the last thirty years we have had many important contributions on this subject, and we now possess a fairly clear knowledge relative to the origin of indol and the formation of indican. There is, however, at present, a rather one sided argument regarding the origin of the indol which is rec-

ognized by the presence of indican in the urine. Slowtzow (5), for instance, divides indicanuria into three forms: First, that due to intestinal fermentation and putrefaction; second, that due to suppuration in some other part of the body, and, third, that due to the formation of indol in the cells of the body tissues. He terms them intestinal, septic, and metabolic, respectively. In the intestinal form he alleges that the indican reaches its maximum four or five hours after the ingestion of food, is diminished by a milk diet and by the administration of intestinal antiseptics, and increased by the drinking of alkaline waters. In the septic type the indican is increased in the evening, is not influenced by the before mentioned measures, and is relieved by removing the septic focus. In the metabolic type the indicanuria is moderate, occurs uniformly throughout the twenty-four hours, is diminished by a milk diet, but is not influenced by intestinal antiseptics, although it may be diminished by drinking alkaline waters. Confirmatory evidence tending to establish the existence of the metabolic type of indicanuria is scanty, and such evidence is considered to be very unsatisfactory. It is undoubtedly the consensus of opinion at the present moment that the indican of the urine depends exclusively upon the production and absorption of indol from the intestinal tract, excepting in those cases in which pathological processes, such as a putrid abscess, putrid bronchitis, pulmonary tuberculosis with cavity formation, the retention of a dead fetus, gangrene, etc., are associated with the formation of the base.

Owing to the fact that indol is a product of proteolytic cleavage it has been stated by Flint (6) and others, that it may be formed by the action of the tryptic ferment of the pancreatic juice upon proteid food. In fact, Flint asserts that indol may be produced in this manner outside of the body. It is, however, quite possible that the indol of these experiments was the result of an unrecognized organic ferment. In this connection Herter (7, p. 260) states that "such a phenomenon could only occur in the intestines in the presence of excessive amounts of proteid food, combined with greatly delayed absorption. Ordinary absorption occurs in the peptone and aminoacid stage of proteolytic digestion, and it is hardly conceivable that in the absence of putrefactive bacteria a rapidly proteolyzed meal should lead to the formation of indol. Furthermore, marked and persistent indicanuria has been observed in dogs from which the pancreas has been removed and also in people in whom autopsy or operation showed both the biliary and pancreatic duct to be occluded." These observations, combined with recent experiments with intestinal antiseptics, with the organized and unorganized ferments, would seem to prove beyond any reasonable doubt that indol owes its origin to the action of certain bacteria upon the proteid food in the intestines.

Regarding the action of the individual members of the intestinal flora upon the formation of indol considerable knowledge is still wanting. Extensive investigations into this perplexing problem are now being made, and although considerable light has already been shed upon the subject, other important findings undoubtedly will soon be reported. It might be stated in a general way that the colon group of

\*Read at a meeting of the Passaic, N. J., City Medical Society, February 11, 1908.

bacteria are unable to break down native proteids, but act only upon the peptones and other products of proteolytic cleavage. On the other hand, there are certain putrefactive bacteria (probably both aerobes and anaerobes) which possess the ability to act both upon the native proteids, the peptones, and the carbohydrates. It appears that some species are able to only partly digest protein food, and the production of indol left to the action of the colon bacilli, while others continue the splitting process and form indol without the aid of the colon group; furthermore, this action under varying conditions may take place in either the large or small intestines. The fact that certain butyric acid forming bacteria are able to attack the carbohydrates with the formation of toxic and irritating substances has led Herter (8) to divide chronic excessive intestinal putrefaction into three types: First, the indolic type, marked by striking indicanuria and probably due to members of the *Bacillus coli* group; second, the saccharobutyric type, which seems to be instituted chiefly by anaerobic forms; in its simplest examples there is very little indol in the gut and very little indican in the urine; third, combined types, or cases combining the characteristics of groups one and two. He not only separates these types by differences in the analysis of the urine and feces, but also distinguishes certain interesting clinical variations.

A consideration of the ætiology is hardly complete without at least a superficial review of the synthesis of indol in the body and the reason for the abnormal bacterial activity in the intestines. Granting that indol is formed in the digestive tube, as stated before, it is next absorbed, combined with sulphuric acid and potassium, and appears in the urine as the indoxyl potassium sulphate or indican. Just where and when this pairing off process occurs is not as yet positively determined, but the trend of recent investigation is to consider that this process takes place very largely, but not entirely, in the liver. In this connection Herter and Wakeman (9) have shown that the body cells, especially those of the liver and kidneys, but also the epithelial cells of the intestines possess the power of oxidizing and pairing off these substances. Petrone and Pagano (10) are of about the same opinion, for as a result of extensive experiments they conclude that the body depends largely upon the liver for protection against the enterogenic poisons. They think the epithelial cells in the walls of the intestines offer the first barrier. Toxines that escape the intestines and liver are acted upon by the lungs, and finally the circulating leucocytes play an important part. Besides these tissues and organs there is little doubt but that the muscles and skin also enter into this process of oxidation and elimination. The nature of the enterogenic toxines and the exact manner in which they exert their deleterious action upon the organism is not well understood. It must be remembered that besides the aromatic products of intestinal putrefaction we have other known bodies, such as the basic substances, the sulphur compounds, etc. From evidence recently advanced it would seem that we have also to deal with the formation of certain ptomaines and other toxic bodies, some of which appear to possess hæmo-

lytic powers, while others seem to act mainly upon the nervous system. That indol itself is toxic to the organism has been amply proved by the experiments of Richard, Howland, and Lee (11), and also by observations to be mentioned later.

It was thought by students of the earlier school of physiologists that certain bacteria, through their ability to do the work of some of the unorganized ferments, were a necessity to health, but this theory has been largely negated by experiments upon animals conducted by Nuttall and Thierfelder (12), and others, who found no difficulty in keeping these animals alive under aseptic conditions in the alimentary canal. Metchnikoff (13, p. 211) cites many observations upon human beings, both children and adults, placed upon aseptic food for long periods, but who remained in perfect health. Such observations would tend to show that the intestinal flora is not essential to life, but they do not prove that certain bacteria existing in the intestines are not beneficial. Indeed, it has been shown by Herter and others that under normal circumstances the *Bacillus coli* group may be of considerable benefit to the organism. As stated by Metchnikoff, "when man enters the world his intestines are practically free from bacteria, but contain a good culture medium for the bacteria, which soon gain entrance by means of air, water, and food." From a theoretical standpoint it is not impossible that if a person always throughout life obeyed the laws of Nature the intestines would soon adjust themselves to the presence of bacteria, and under favorable conditions the harmless and protective species would predominate and defend the individual against the invasion and injurious action of the undesirable microbes. One can hardly help but think that primitive man suffered very little from gastrointestinal disturbances, but with the advancement of civilization, the crowded conditions of city life, the lack of physical exercise, the hurried eating, the worry, hurry, and excessive loss of nerve energy associated with the gaining of a livelihood, together with the inferior character of the food obtainable, it is no wonder that a suitable soil is prepared for the growth of harmful organisms in the intestines. An extremely long large intestine has, for various physiological reasons, always been considered a necessary part of human anatomy, but very recently Metchnikoff (14, p. 70) has advanced the opinion that a large part of the large intestine is rudimentary, that it has acquired in common with other rudimentary organs a lowering of vital resistance, thereby forming one of the many disharmonies of the human race in its present stage of evolution. He cites many experiments and observations to verify and fortify his interesting hypothesis, which, if found to be true, will certainly help one to understand why people of to-day are so susceptible to diseases of the gastrointestinal tract.

#### Diagnosis.

Although the rapid or slow absorption of the enterogenic toxines may produce a more or less typical picture of intestinal autointoxication or enterotoxism, a positive clinical or symptomatic diagnosis can, for obvious reasons, only be made in a limited number of cases. But in the absence of putrid processes elsewhere in the body the presence

of indican in the urine is positively indicative of intestinal putrefaction. There are several methods of testing for indican, the most of which are adequately described in the textbooks. The accurate quantitative methods are extremely difficult, and fall within the domain of the analytical chemist. Such procedure, however, is hardly necessary, for, if conducted in a methodical manner and especially if frequently performed for the purpose of obtaining the average reaction for the individual, the qualitative tests will give a very fair idea of the variable amount of indican voided, and in many cases will indicate the intensity of the intestinal putrefaction and the amount of absorption of toxic substances. Certain important exceptions must be considered. In negative reactions, for instance, the possibility of injurious types of saccharolytic fermentation must be considered. Again, the quantity of indican in the urine, although indicative, cannot be taken as a criterion of the amount of harm being done, because so much depends upon the nature of the toxins produced, upon the ability of the system to properly oxidize, pair off, and eliminate these substances, and also upon the amount of absorption from the intestines. It is desirable, therefore, to consider not only the presence of indican, skatoxyl, sulphuric acid, and ethereal sulphates in the urine, but also the severity and character of the symptoms presented. Furthermore, in considering individual cases where it is desirable to establish the relationship between the symptoms presented and the associated indicanuria it is essential that one take advantage of diagnosis by exclusion. In other words, one must exclude to the best of his ability all other aetiological factors, or if other possible causes are present, to estimate the probable significance of the indicanuria, which may be accomplished by careful study and by the aid of therapeutical measures.

In testing for indican it is advisable to decide upon one reagent, and always employ it in a definite manner. The following modification of Obermayer's test has given me great satisfaction: The reagent consists of a stock solution, composed of a 0.3 per cent. solution of C. P. ferric chloride in pure hydrochloric acid. Five cubic centimetres of this reagent are added to the same volume of urine in a test tube; 1 c.c. of chloroform is added to this mixture, and the tube inverted several times. If indican is present the chloroform, which rapidly settles to the bottom of the tube, will assume a blue color, the intensity of which depends upon the amount of indican in the urine. Occasionally the splitting of the potassium indoxyl sulphate is delayed, so in all negative cases it is advisable to allow the mixture to stand for several minutes before venturing an opinion. In mild reactions better contrast can be obtained by replacing the urine with water, leaving the chloroform at the bottom of the tube, or the urine may be clarified by filtration after the addition of a few drops of a saturated solution of lead acetate. Occasionally one will obtain a purplish or red, instead of a blue, reaction. This is probably due to the presence of skatoxyl compounds. The significance is the same, providing the patient has not been taking potassium iodide, which will give a red reaction with this re-

agent. Any doubt can be cleared up by the addition of a few crystals of sodium hyposulphite.

#### *Pathogeny.*

Physicians are frequently at a loss to know how to interpret their indican findings. They will no sooner arrive at the conclusion that certain diseases or disturbances are always associated with indicanuria than their calculations will receive a setback by the demonstration of large amounts of indican in apparently normal beings, or the disease usually associated with more or less indicanuria will be found to exist without any reaction to the Obermayer test. The proper interpretation of indicanuria is not easy, and depends upon the recognition of several important factors. In the first place, it is necessary to determine if the indicanuria is temporary or permanent. If temporary one would hardly expect more than mild, febrile disturbances associated with lassitude and signs of gastrointestinal irritation, depending, of course, upon the severity of the attack. If permanent then one must look for evidence of systemic disturbance, and in a majority of cases such evidence will usually be demonstrated by the presence of various local or general manifestations of disturbed metabolism. It has already been stated that the effect of intestinal putrefaction depends largely upon the absorption, oxidation, and pairing off of the toxic material. As long as the tissues entering into this process are normal and able to cope with these substances no harm other than an increased amount of work for important organs will be produced. But just as soon as these tissues become impaired by overwork or disease, then various local or general symptoms of toxemia are likely to manifest themselves. The question of idiosyncrasy is possibly no more than a question of synthesis. However this may be, we observe the same relation between cause and effect in the case of indicanuria as we do in the case of many of our important drugs. Quinine, the salicylates, the iodides, and bromides, all produce very distressing symptoms in certain individuals, while others may partake of them with impunity.

In cases of chronic, persistent indicanuria, where no deleterious effect is observable, it must be remembered that relatively small doses of poison are being absorbed into the circulation for a period of months or years, and in many of these individuals the evidence of disease may not manifest itself until the age of fifty or sixty. We are accustomed to use the inappropriate word toleration to account for such phenomena, and the same picture is portrayed in many cases of chronic alcoholic indulgence and by the long continued use of any one of many drugs. It is largely this effect of chronic intestinal autointoxication that has led Metchnikoff to write his latest book, *Essais optimistes*, which, like *Nature of Man*, is a study in optimistic philosophy. In these works he considers the phenomenon of old age, and concludes that the autointoxication derived from chronic intestinal putrefaction is one of the most important causes of premature senility, chiefly through its influence in inducing arteriosclerosis.

It is possible to divide the effect upon the system of the enterogenic poison into acute and chronic.

The acute cases represent the sudden absorption of large quantities of toxic substances from the intestines in individuals, who, as a rule, are free from indicanuria. Or the acute symptoms may occur as an exacerbation in the course of a chronic intestinal autointoxication. Both forms are common. The cause of these attacks is usually some indiscretion in diet or perchance to hygienic disobedience, but in many cases it is impossible to ascertain the cause. The symptoms of acute exenterotoxism are fairly typical, the most usual of which may be grouped under the term of biliousness. Mental and physical fatigue, anorexia, vertigo, and similar manifestations are usually prominent. Occasionally one meets with a very severe case, presenting gastric pain and vomiting, with or without diarrhoea. For some time I have noticed the interesting fact that many individuals are able to forecast with a surprising degree of accuracy the outcome of the test for indican. These patients appear to be able to distinguish between muscular fatigue, the weariness from insufficient sleep, certain hygienic indiscretions, and the "dopy feeling," as they express it, which is produced by a mild intestinal autointoxication.

In the chronic type of intestinal autointoxication we have to deal with the more or less slow absorption of relatively small amounts of indol and other toxic substances. The clinical picture is totally different from that portrayed in the acute type—in fact, the symptoms, diseases, or conditions produced depend largely upon the nature of the toxins generated and the idiosyncrasy of the individual as a whole and the resistance offered by the local tissues. It is, therefore, practically impossible to classify the symptoms of chronic excessive intestinal putrefaction, but inasmuch as its effects are now being seriously considered in all branches of medicine it will be profitable to give a somewhat superficial review of the more important recent literature.

It has long been known that gingivitis, Rigg's disease, and other similar affections could be caused by various nutritional disorders and by certain toxic substances. It is, however, only within the last few years that the dental profession has devoted attention to intestinal autointoxication in relation to these diseases. F. L. Stanton (15), of this city, was probably one of the first dentists to recognize the possibility of an intestinal autotoxic factor in pyorrhoea alveolaris. In collaboration with Dr. R. H. Potter, he examined a large number of patients, and found an excess of indican in about 98 per cent. of the cases. Talbot (16), of Chicago, has devoted considerable study to this subject. Although recognizing all forms of autointoxication as well as local aetiological factors, he considers that intestinal putrefaction deserves very careful consideration. He is of opinion that toxins in the circulating blood act chiefly upon the end organs, of which the gums and alveolar processes are examples, and that the injurious effects are produced by their action upon the bloodvessels. Fossune (17), of New York, is also an enthusiastic believer in the constitutional origin of Rigg's disease, and considers the constant presence of an excessive indicanuria as being very significant.

Taking the advice of Sabaroud, to the effect that

the dermatologist should devote more attention to diseases of the superficial mucous membranes and being interested in the subject, I have, in collaboration with several dentists, treated a few cases of Rigg's disease. In some of these cases it was possible to exclude diabetes, syphilis, nephritis, acidosis, alcoholism, etc. Without going into details these patients all presented an intense indicanuria, and many of them, besides their Rigg's disease, had attacks of vertigo, gastrointestinal disturbances, anaemia, skin eruptions, etc. As a result of a careful study of these cases I believe that as a result of treatment they are not only in better health, but that their mouth condition improved with a greater degree of rapidity under local surgical measures instituted by the dentist than had been the case previously. It is too soon to predict the ultimate effect upon this disease by treatment directed at the indicanuria, but evidence so far at hand would indicate that a considerable addition to permanency might be expected.

The neurologist finds indicanuria to be associated with many disorders of the nervous system, particularly with neurasthenia and various forms of neuritis. Cleghorn (18), in a report of six thousand cases of neurasthenia, finds that among the causative factors the disturbances of the gastrointestinal tract and the autointoxication therefrom stand out as conspicuous examples. Combe (19), Herter (20), and others place considerable importance upon the relationship existing between neurasthenia and intestinal putrefaction. Herter, for instance, considers the state of debility that we call neurasthenia as being one of the clearest clinical signs associated with certain types of intestinal putrefaction. During the past year several general practitioners, at my suggestion, have studied this question, with the result that a marked indicanuria was found to be present in a large percentage of the cases. The achievements of treatment in these cases were exceedingly interesting and instructive, and as a consequence of these observations I am of opinion that intestinal putrefaction is the cause of many, a means of exaggerating the symptoms in some, and possibly the effect rather than the cause in other cases of neurasthenia. Among other diseases of the nervous system, neuritis, progressive muscular atrophy, and various reflex disturbances are thought to be due to the enterogenic toxins. Mennella (21), for instance, in an article dealing mainly with the question of autointoxication and neurasthenia, not only believes intestinal putrefaction to be the cause of most cases of this character, but is of opinion that many cases of obscure reflex nervous symptoms, cephalalgia, various neuroses, and psychoses are of autotoxic origin, and especially from intestinal putrefaction.

Among the diseases lying mostly within the domain of the general practitioner and thought to be occasionally caused, or at least greatly exaggerated by intestinal autointoxication, may be mentioned certain types of chronic arthritis, muscular rheumatism, anaemia, cystitis, renal irritation, etc. In fact, it is now generally considered that the recovery from many diseases can be retarded by the presence of an excessive indicanuria, for the simple reason that the tissues have to deal with an ad-

ditional toxæmia. Landers (22) has resurrected the old idea of giving intestinal antiseptics in cases of typhoid fever, asserting that the good results obtained are due to the lessening of intestinal auto-intoxication, thereby overcoming the battle of the body tissues against these toxins. In this connection it might be stated that there are cases of intestinal putrefaction, which possess many of the symptoms of typhoid. Through the courtesy of a professional friend I recently had the opportunity of observing such a case. In this patient the attack was preceded by a severe vertigo, which lasted a month, at the end of which he had a temperature of 103° F., and presented many of the clinical manifestations of typhoid. The blood failed to respond to the Widal test, and the urine to the diazo reaction, but it did show a very marked indicanuria. The most curious feature was an eruption upon the abdomen closely resembling the well known rose spots. This eruption later developed into an extensive and typical erythema multiforme. The patient made a rapid recovery, both from his symptoms and his indicanuria when placed upon salol and a milk diet.

It is the opinion of several investigators that through the hæmolytic effect of certain intestinal toxins profound grades of secondary anæmia may be produced. In fact, it has been asserted that intestinal putrefaction may have an important bearing upon the production of primary anæmia. In this connection Olin (23) reports a case of simple anæmia with the hæmaglobin reduced to 30 per cent. and associated with a persistent indicanuria. Measures taken to overcome the intestinal putrefaction restored the patient to comparative health.

Several attempts have recently been made to associate indicanuria with renal irritation. Williams (24), for instance, reports six hundred urinary examinations in which he found one half the cases of albuminuria had an associated indicanuria, which apparently increased in severity with the increase in the albuminuria. He also found that in many of these cases the albuminuria rapidly subsided when attention was directed to the intestinal putrefaction. Darenberg and Perroy (25) found that in 95 per cent. of the cases in which the urine contained a great excess of indican there was likewise an albuminuria. Houghton (26) mentions three interesting cases of interstitial nephritis in which the administration of intestinal antiseptics was of the greatest value. It is quite reasonable to suppose that the excessive work demanded of the kidneys in eliminating such poisons may weaken these important organs. At any rate, there is sufficient evidence at hand to show that indicanuria represents a serious obstacle to the recovery of a diseased kidney. It is a well known fact that indicanuria is frequently, if not always, associated with increased arterial tension, and the proper attention to this indicanuria will not infrequently alleviate the strain placed upon the kidneys, circulatory system, and other important organs and tissues.

In recent literature one finds frequent mention of intestinal putrefaction in connection with a number of the organs of special sense. Dr. Schweinburg (27) in a very interesting paper, deserves considerable attention to intestinal auto-intoxication as an etiological

factor in the various diseases of the eye. He reviews the literature to some extent, and concludes that although the heterogeneous auto-intoxications may not be the sole cause of certain ocular disturbances they are at least contributory, and frequently are the means of a continuance of symptoms after the more commonly accepted ætiological factors have ceased to be active. The interesting discussions of this article by Wood, Bull, Marple, Posey, Weeks, and others were remarkably enthusiastic and strongly fortified the author's contentions.

In pædiatrics considerable attention has been given the subject of indicanuria as bearing upon the gastrointestinal complaints and malnutrition of infants. Veitch (28), for example, reports the cure of a child which appears to warrant the adoption of suitable means to overcome intestinal putrefaction in most cases of infantile malnutrition when associated with such process. Dunn (29) distinguishes between infectious diarrhœa and that produced by intestinal fermentation and putrefaction. Judson and Clock (30) mention several cases of marasmus successfully treated by the use of buttermilk, which, as will be seen later, is one of the most important means of combating intestinal putrefaction. Combe, in his various writings, recites experiments, observations, and investigations which strongly fortify these findings. Herter (7, p. 284), in collaboration with Holt, has investigated the group of cases that are characterized by the marantic, large belly type of chronic intestinal indigestion in children. To use Herter's words: "All physicians agree that this form of digestive trouble is extremely obstinate to ordinary methods of treatment. It is usually manifested by a distinct retardation of growth, muscular weakness, distension of the abdomen by gas, and voluminous, light colored, usually gray, and fatty stools. The urine of such cases usually contains an excessive amount of indican, phenols, and ethereal sulphates. Regulation of diet and hygiene in accordance with our knowledge of the action of bacteria in the intestines has been of considerable service in the treatment of these cases."

Although there is a very close relationship existing between the cutaneous diseases and intestinal auto-intoxication the scope of this article is too general to allow but a few words on this interesting subject at the present time. Engman (31) who has studied the significance of auto-intoxication in dermatological disorders, pays particular attention to the presence of a marked and persistent indicanuria in cases of pompholyx and dermatitis herpetiformis, and is of opinion that the toxins derived from intestinal putrefaction may be an important ætiological factor in many of these cases. Johnson (32) has considered the evidence of an antitoxine factor in eczema, and particularly in the bullous diseases, and concludes as a result of routine urine examinations, the clinical manifestations of these diseases, as well as the therapeutical results obtained, that auto-intoxication in relation to dermatology should receive careful attention. He believes that the auto-intoxication in many cases has its origin in the failure of protein metabolism, and while placing considerable importance upon the various toxic substances found in the urine, together with the est-

mation of the total nitrogen output, he also considers the presence of an indicanuria as very significant. Personally, I have never failed to obtain a marked indican reaction in cases of pompholyx or dermatitis herpetiformis, although in this connection it might be stated that Schuyler Clark, at a recent meeting of the dermatological section of the Academy of Medicine, January 7, 1908, reported a very severe case of dermatitis herpetiformis which had never presented an indicanuria. Indicanuria is not infrequently associated with eczema, psoriasis, urticaria, erythema multiforme, pruritus, etc., and although a definite relationship between these diseases and intestinal autointoxication has not as yet been established, there is little doubt but that some such cases may be produced in this manner, while in others the indicanuria represents a possible contributory cause. Clinical observation of individual cases certainly tends to confirm such opinion, and, furthermore, as a result of such observations, I believe that intestinal autointoxication may possibly have an influence in establishing individual susceptibility to various cutaneous irritations. In concluding this subject I am of the opinion that superior average results are obtained in many cutaneous eruptions when proper attention is directed to an associated indicanuria.

#### *Treatment.*

*Diet.*—Inasmuch as indicanuria is caused by the action of certain bacteria upon the proteids, it is essential in most cases to restrict the amount of this type of food. I think it is a good plan in these patients to limit animal food to one meal a day. In some instances it is necessary to abstain, for a time at least, from all nitrogenous food. Occasionally, however, one encounters a case that appears to be unable to tolerate a farinaceous diet. Both Herter (20) and Porter (33) have also found this to be the case. The latter objects to a vegetarian diet, because he considers such food hard to digest, while the former asserts that under certain conditions the growth of the gas bacillus is favored by an excess of the carbohydrates. It is obvious, therefore, that no absolute rule can be given regarding dietary measures, for each case is a law unto itself. A very important desideratum is the promotion of prompt absorption, which may be accomplished by the use of such vegetable foods as rice, or, in certain cases, an exclusive milk diet may be advised with benefit. Thorough mastication is also very important, and I have seen excellent results follow an adaptation of the rules of mastication as formulated by Horace Fletcher in his *A. B. Z. of Nutrition*. The entrance into the stomach of putrefactive bacteria must, as far as possible, be avoided. If the gastric secretions are normal, most of these bacteria are destroyed, but when defective, and especially when considerable mucus and desquamated epithelium is present, such organisms are not only able to survive, but may actually find a favorable medium upon which to multiply. In such cases this object may be attained by the proper cooking of food, by thorough mastication, and by attention to the teeth.

*Hygiene.*—Hygiene in many cases is of as much importance as diet. Proper exercise and bathing will aid metabolism, elimination is increased, and

the digestive functions strengthened. The prevention of worry, anxiety, etc., must be avoided if possible, for the effect of enthusiasm, suggestion, or by whatever term it may be called, upon metabolism is not well understood, but very likely it has been underestimated.

*Medicine.*—The digestive mixtures may, for obvious reasons, be of service when indicated. The so called intestinal antiseptics have been and are still being employed to control intestinal putrefaction. Although such drugs as salol, dermatol, etc., may reduce the urinary indican, it is hardly advisable to use such preparations for protracted periods. In the first place, we do not know what deleterious effect such drugs may have when taken indefinitely. Again, it is possible that such measures influence the protective members of the intestinal flora as well as the harmful invaders. In any event, it has been found that patients fail to do as well as expected when treated in this manner. This opinion receives confirmation by the published observations of Herter (7, p. 329), Metchnikoff (13, p. 204), Steele (34), Conner (34), and others. It is an opportune moment to say a word regarding constipation. Although cases of obstinate constipation, without an associated indicanuria, are to be met with, the opposite condition of affairs is more frequent. It is advisable to overcome the sluggish action of the bowels by other than medicinal means, but not infrequently it is necessary to resort to laxative measures. In this connection it is interesting to note the observation of Maberly (35), who finds that sodium sulphate in small doses acts not only as an aperient, but also as an intestinal antiseptic through the liberation of oxygen during the process of chemical decomposition. Intense and persistent indicanuria is sometimes met with in cases of chronic diarrhoea, and not infrequently the diarrhoea, flatulence, etc., will continue after the indican has been reduced. In such cases it is possible that certain bacteria are acting upon the carbohydrates with the production of irritating acids. In these patients, if other means fail, the temporary use of bismuth subnitrate may be of service. In passing I might call attention to the fact that lavage of the colon and stomach in both adults and children has been of benefit in disturbances of these organs when associated with intestinal putrefaction and autointoxication.

*Bacterial antagonisms.*—Through the possibility of the formation of specific antibodies by the influence of putrefactive bacteria in the intestines some work has been done in hopes of obtaining a specific bacterial vaccine or specific bacterial sera. Such investigations, although to be commended, have not as yet been attended with laudable success. Tissier (36) by analyzing the bacterial contents and determining the special bacillus causing the disturbance has been able by modifying the diet and infecting the individual with microbes antagonistic to the one at fault to obtain very good results. But as stated by Combe (37): "It is very difficult to individualize an intestinal infection, and in the majority of cases it is only possible to determine whether the flora is saccharo or proteolytic. This is sufficient to indicate the régime and the nature of the antagonistic bacteria. When it is possible in

every case, as Tissier does in some, to determine exactly the individual germ which is at the bottom of the trouble, it will be feasible to find its direct antagonistic microbe. The method of individualized intestinal infections is still a laboratory method which cannot enter into general practice."

**Sour milk.**—That sour milk is of benefit both in health and disease has been known since the earliest biblical times. For many centuries the inhabitants of Eastern countries have employed it as an article of diet. Passing from antiquity to modern times we find that buttermilk, or sour milk, is a favorite aliment among the people of many countries. The medical profession has long recognized the value of sour milk in disease. Piffard (38) has, for the past twenty-five years, directed many patients to use it both for dietetic and directly remedial purposes, and for the past thirty years many physicians have advised the use of certain fermented milks as an aid to digestion and nutrition. Metchnikoff (13, 14) has noted the interesting fact that individuals who have existed largely upon sour milk and vegetable food have attained a very old age and were remarkably well preserved both mentally and physically. Furthermore, he is of opinion that such milk, by preventing the deleterious effect of intestinal auto-intoxication on the circulatory system, will greatly aid in prolonging life, and if this is found to be true we have indeed, in sour milk, the nearest approach to the long sought elixir of life. In 1892 Rovighi (39), an Italian physician, drank daily a litre and a half of milk subjected to lactic acid and alcoholic fermentation. He found that in a few days the products of intestinal putrefaction in his urine were greatly reduced. In 1897 Herter (40) reduced the amount of indican in dogs by injecting pure cultures of lactic acid bacilli into the small intestines. In 1902 Bienstock (41) and Tissier and Martelly (42) proved the existence of certain bacteria in milk that prevented its putrefaction. Such observations explain why sour milk is of such value as a medicine. They also show why lactic acid will control certain cases of infantile diarrhoea. In any advent, the writings of Herter, Combe, Metchnikoff, and others have stimulated interest in a much neglected subject, and in recent months several instructive articles have appeared testifying to the efficacy of sour milk as a medicine. Dunn (29), Veitch (28), Batten (43), Morse and Bowditch (44), Judson and Clock (30), and Strauch (45) have found buttermilk of considerable service in certain forms of infantile diarrhoea, intestinal auto-intoxication, and malnutrition. As a result of personal observation I can state that sour milk will control the majority of cases of indicanuria, but is this effect the result of the lactic acid contained therein, or the colonization of the lactacid microbes in the intestines? As has already been mentioned Herter succeeded in modifying the indicanuria in dogs by the use of pure cultures of lactacid organisms. Tissier (46, 19) obtained good results in cases of intestinal putrefaction by employing pure cultures of certain lactic acid forming bacteria grown in peptone lactose broth. Combe (37) states that the bacillus of Massel (*Bacillus butylicus* of Metchnikoff), which is one of the organisms found

in Bulgarian curdled milk, may be demonstrated in the faeces of patients taking such milk. He also cites many favorable results obtained with both soured milks and with pure cultures of the various lactacid organisms. On page 223 of the *Essais optimistes*, Metchnikoff, as a result of numerous experiments, conducted by himself and others, is of the opinion that certain lactic acid forming organisms are able to colonize in the intestines, and that sour milk is of benefit not alone through its lactic acid, but also on account of the large number of desirable bacteria contained therein.

I have found that although lactic acid will control indicanuria to some extent, the indican will return to its original degree very soon after the acid is discontinued. Buttermilk and milk soured by means of native bacteria will, in many instances, completely control an indicanuria, and in some of my patients who have taken such milk for a considerable period and especially when placed upon a diet favorable to the growth of the lactacid organisms, there has apparently been a complete cure effected, making a continuation of the milk unnecessary. It has also seemed to me that milks fermented by certain foreign bacteria are more powerful and produce a more permanent effect than is the case with the native organisms. In experimenting with pure cultures I have utilized the lactobacilline tablets from Paris, the lactone tablets from Detroit, the yogurt capsules from Battle Creek, and some cachets which were specially prepared for Dr. Piffard. When employing these preparations it must be remembered that we are giving only relatively small numbers of bacteria, and they must, in some cases at least, be given over an extended period of time and combined with a favorable diet before their effects become clearly manifest. On the whole, I believe I have noticed good results from the use of these preparations, especially with the ones containing foreign organisms. Piffard (47) has also experimented with pure cultures, and finds that they control the indican output. Although a more rapid and positive action may be obtained by the use of soured milk, the cultures given direct are especially convenient for those individuals who cannot or will not tolerate any form of sour milk.

Although these observations would seem to verify the contention to the effect that under favorable circumstances certain lactacid organisms are able to colonize in the intestines, such a theory requires further fortification before it can be said to rest upon a firm scientific foundation. In this connection it might be stated that Herter (20), in his latest communication, is inclined to doubt the ability of lactacid organisms to permanently colonize and displace the putrefactive bacteria. He finds that intestinal putrefaction may continue in spite of the free or even exclusive use of fermented milk. Furthermore, he asserts that there is no evidence whatever that the lactacid organisms are able to restrain specifically the growth of *Shewanella putrefaciens*. He considers that any limitation in the growth of the putrefactive organisms depends upon the absence of carbohydrates in the fermented milk and in the presence of lactic acid. The amount of fermented milk possessing certain advantage over

fresh milk, but considers this to be due chiefly to the ability of the bacilli to make lactic acid freely from the soluble carbohydrates and to subdivide and transform the casein in such a way as to render it more readily absorbed than that of ordinary milk. It is to be hoped that further investigations will soon be made in this line, not only in the case of *Bacillus aerogenes capulatus*, but with other proteolytic anaerobes and in the case of the overactivity of the members of the *Bacillus coli* group. Such investigations are desirable, because we have thus far depended largely upon clinical observation, which is notoriously uncertain unless conducted by a number of different men over a protracted period of time.

For the lack of time and space it will be impossible to enter into a discussion regarding the relative value of the various sour milks and the preparations made therefrom. I respectfully refer those who are desirous of studying this important phase of the question to an excellent article recently published by H. G. Piffard (38), in which is recorded the result of an exhaustive bacteriological study of sour milks, and also to an article by Combe (37), who gives the method of preparing and taking of yoghourt and other products used as an article of food in eastern Europe.

I desire to state, however, that considerable caution must be exercised in selecting from among the artificially soured milks recently placed on the market, for one or two of these preparations have produced very untoward results. In choosing these products one should always consider the reputation of the firm making them. I am of the same opinion as Dr. Piffard in respect to the wholesomeness of most of the soured milks sold in New York City under the name of buttermilk. Finally, if one desires to do so, a good grade of whole milk may be soured at home by infecting it with a culture of suitable lactic acid organisms and the product consumed daily.

## A CASE OF ACCESSORY SINUS DISEASE WITH THE SYMPTOMS OF AN OSSEOUS TUMOR OF THE ORBIT.\*

BY BURTON CHANCE, M. D.,  
Philadelphia.

The subject of this report was a lad of fourteen who a year previous to his coming under my observation had noticed a reddened swelling at the inner side of his right orbit. He had been told at a local dispensary that this was caused by "tear duct trouble." The swelling was soft at first, but in eight months it became hard, and began to increase in size and density, though without pain. Later, the eye became slightly displaced, and the patient grew anxious because of a very annoying diplopia.

When I examined the boy for the first time, in January, 1905, the inner half of the orbit was occupied by a bulging mass, and the eye was pushed outward and downward, and could not be rotated inwardly. The mass was dense and appeared to have its base at the nasal and lacrimal bones and along the inner orbital wall. It extended laterally into the orbit about a half inch, and it could be palpated for three quarters of an inch horizontally backwards. It was irregularly nodular in shape, and projected forward to about the vertical plane of the cornea. It was not sensitive even to deep pressure. The tear ducts gave free passage to small Bowman's probes.

The patient was active and wiry, a member of a boys' choir and inclined to pay much attention to his personal appearance. He had never been annoyed by colds in his head, and had never received any injury to his orbital or facial bones.

There were no obstructions in the nasal or faucial passages, nor were there discharges on their membranes. The accessory sinuses were not examined as there was no symptom of such importance to lead me to believe they might be diseased. I did not express an opinion upon the probable cause of the swelling in the orbit. The patient was instructed to use an alkaline nasal douche daily and he promised to return to my office in two weeks.

He returned in ten days because of marked conjunctival congestion and he said he could not see so well with the right eye. The acuity of vision was 5/15. The optic disks were pale, though the retinal veins were engorged. I believed then that a bony tumor had involved the inner wall of the orbit, and, because it appeared to be pressing upon the ocular structures, I advised the boy's mother to have the tumor removed, but I requested her to consult a general surgeon before she accepted my opinion. She took the boy to Dr. Gwilym Davis, and he gave an independent verdict that it was an exostosis of the orbit, and urged the immediate excision of it.

On February 4, 1905, with Dr. Davis assisting me, I undertook the operation at the private building of the Germantown Hospital. The incision was begun along the upper orbital margin, carried in a semicircle down over the tumor, and ended at about the middle of the lower margin. The soft parts were separated deep into the orbit. Rather free hemorrhage followed. The tumor was circumscribed and projected irregularly. In the direction of the incision the instrument suddenly penetrated the bone, and a head of thick (tumor) matter extended. This opening was a core enlarged to the full size of the tumor. An enormous (incredible) amount of thick mucus was removed before the cavity could be exposed, then it was found that the eth-

moidal sinus had been entered. The cells had been absorbed so that exploration was carried on easily. The cavity extended back to the sphenoid, up to the frontal sinus, and the inner concavity to beyond the median line, while the outer wall projected far into the orbit. The walls were scraped; and as there was no opening into the nose, one was made with the curette. Two rubber drainage tubes were inserted, one far back into the cavity, the other upwards and forwards, and brought out through the nostril. The soft tissues were placed over the orbital opening, and the wound was closed by several silk sutures. The dressings included the tubes.

The patient recovered promptly, and no untoward events occurred. The cavity was douched daily with solutions of hydrogen dioxide. After six days the tubes were withdrawn, and the sutures were removed, so that in eight days the boy was able to come to my office for treatment. The aperture in the ethmoid allowed free drainage to continue into the nose.

For about four weeks the external cicatrix remained prominent, but it became reduced when the osseous aperture began to be filled in. Two months later the sinus was draining satisfactorily, though a plug of mucus was held in the opening; and, when deep pressure was made over the orbital opening a bubbling sound was emitted as though there was an accumulation of mucus. The boy stated there was no noticeable discharge from his nose. He had great comfort. The eye had become straight again; he was relieved of the diplopia, and the vision had returned to normal. The optic nerve had lost its pallor, and in all respects the fundus appeared to be as healthy as that of the other eye.

On November 16, 1907, nothing but the cutaneous cicatrix and a rather broad nasal bridge gave external signs of the former state, while the visual and ocular conditions were normal, and the nasal cavities were healthy.

The case is interesting on account of the question of diagnosis. Had the tumor been soft and painful, or had there been discharge from the nose, the ethmoidal origin of the trouble would have been suspected. But all these were absent, and the extreme hardness of the tumor, with lack of tenderness or pain or nasal trouble, caused one to regard it as a possible osseous tumor. The characteristics were explained by the fact that the bone was bulged forward, and the enlargement was really beneath it instead of above it.

## WINTER DIARRHŒAS IN INFANT FEEDING.

By E. KIRKLAND SHELMERDINE, M. D.,  
Philadelphia.

Extreme cold in winter as well as the extreme heat of the summer has its influence upon the progress of an infant who is being artificially fed. The diarrhœas which the physician is called upon to treat in summer are well known, but the diarrhœas which arise in the winter months are more puzzling as to their origin.

I must confess that up to recently I laid the main cause of winter diarrhœas to other reasons than the true one. I always blamed the cause to a too high percentage of fat, some carelessness in the preparation of the food, or to some accidental infection of the gastrointestinal tract due to the swallowing of microorganisms taken into the mouth from an unclean nipple, a teething ring, or some such object given to the baby to put into its mouth.

In my own hands held six four months' old infant was attacked by a diarrhœa during a spell of cold weather which had all the symptoms of the diarrhœa which occur in the summer months from

\*Read at a meeting of the Section on Ophthalmology at the Conference of Physicians of Philadelphia, February 2, 1908.

impure and contaminated milk. He was being fed on a certified cream and milk mixture; when the diarrhoea assumed the proportions of from eight to twelve stools a day I accused the mother of a lack of care in the preparation of the food, and volunteered to prepare it myself until conditions improved. Both the cream and the milk were left early in the morning before any of the household were out of bed, and when they were brought into the house both were frozen. After thawing out the milk and cream and making the mixture, I noticed that there were fine particles floating on the top; if the mixture was allowed to stand there would be quite a number, which would rise to the top. I came to the conclusion that the milk was not good, and telephoned the dairy, accusing them of leaving old milk, informing them of what I had found. They indignantly denied that old milk had been left at my place, and asked me if the milk had been frozen; I replied that it had. They informed me that if that was the case, the freezing was responsible for the small curds; and said, furthermore, that it was a well known fact among milkmen that freezing milk spoiled it. As it was not convenient to procure a fresh supply of milk, I strained the mixture through cotton and removed all the curds; this strained mixture was fed to the infant, and his diarrhoea disappeared by night.

By making arrangements to have the milk left at a later hour in the morning and thus preventing its freezing from being left out in the cold, and having the milkman take precautions to keep it from freezing en route, there was no further trouble on the score of minute curds in the milk. After preventing the milk from freezing there was no further trouble with diarrhoea. Since my attention was called to the cause of the diarrhoea in my own infant, I have found it also to be responsible for what was formerly puzzling diarrhoea in other infants under my care; precautionary measures adopted to prevent the milk from freezing brought about prompt relief.

When the milk is frozen, the water in it is congealed into ice, the perfect solution of the casein in the water is disturbed, and there results a clumping of the proteid molecules which lose their solubility; on the reduction of the frozen mass to a liquid, the curds, through some chemical change brought about by the freezing, are incapable of acquiring the solubility which they formerly possessed. These minute curds cannot be broken up by pouring the milk from one jar into another, by agitation, or by heating, and are present in the final mixture.

Certified milk, as a rule, contains very few bacteria when compared with ordinary milk; yet it has some, enough under favorable conditions to multiply into immense numbers. This clumping of the casein carries with it the majority of the bacteria suspended in the milk. These clumps in the gastrointestinal canal of the child are difficult to digest; the digestive juices do not break them down into assimilable forms, the rennet in the child's stomach is not capable of bringing about the molecular changes necessary for the proteolytic action of the gastric and pancreatic juices—in other words, tough

curds are ingested which are difficult to digest. These curds undergo decomposition in the intestines and are excellent foci for the multiplication of the bacteria with which they are loaded, as well as for the omnipresent microorganisms normally in the intestinal tract.

The diarrhoea caused by frozen milk is not as severe nor as debilitating as that of the summer season; neither are the number of stools as great. Six to twelve stools a day is the average. There is distressing colic. The stools are green, acid, watery, and contain small cheesy masses of undigested casein; the buttocks are generally excoriated from the irritative effects of the acid stools.

Treatment consists in taking the child off the milk diet for twenty-four hours, cleaning out the bowels, and giving barley water in the interim. If the condition is recognized early, correction of the underlying cause will produce a prompt subsidence without the necessity of stopping the food.

6135 GERMANTOWN AVENUE.

#### A CASE OF ACUTE DOUBLE MILIARY TUBERCULOSIS OF THE CONJUNCTIVA.\*

By HOWARD F. HANSELL, M. D.,  
Philadelphia.

A Lithuanian, aged thirty-seven, having successfully passed the physical examination, was admitted to the United States through the port of New York in June, 1906. He stated that he had been healthy all his life and had had no trouble with his eyes until nine weeks ago, five weeks before he applied at the Out-Patient Eye Department of the Jefferson Hospital. At this time he presented to superficial external examination the characteristic appearance of trachoma, so common among the Russians who apply at the clinic. The skin of both upper lids was discolored, and the lids were swollen and drooping. On the palpebral surface the resemblance was equally marked. Scattered over the conjunctiva of both upper and lower lids were numerous yellow, isolated swellings that might at first glance be mistaken for trachoma follicles. Close inspection showed that the yellow patches were not granulations or enlarged follicles. They were round or oval, the size of a grain of wheat, circumscribed and sharply separated from the adjacent membrane, yellow in color as though they contained pus or caseous matter, slightly raised above the surface of the membrane and covered by epithelium. They were shallow, not penetrating as far as the tarsus. I had never seen a similar case and was uncertain as to the diagnosis. Dr. Rosenberger, of the pathological laboratory, collected some of the material from the surface of the conjunctiva by gently scraping and reported the presence of numerous tubercle bacilli. Examination of the contents of one of the little caseous like elevations had been commenced, but not completed. No signs of general tuberculosis could be detected by examination of the lungs, sputum, or urine by Dr. d'Apercy, of Dr. Cohen's medical clinic. The preauricular or cervical glands were not enlarged. The eye grounds were healthy, V. = 6/6 with —7.5.

Tuberculosis of the conjunctiva is usually acquired from sources external to the body, such as the dried sputum of tuberculous patients, a previous traumatism, and, as Fuchs has shown that, since many cases originate in the small fold of mucous membrane near the inner canthus, it may arise from the lodgment there of minute foreign bodies carrying the bacilli. Tschernomolow speaks of a case in which tuberculosis of the conjunctiva was implanted by the tongue of a tuberculous woman who at-

\*Read before the Section in Ophthalmology, College of Physicians, December 17, 1907.

tempted to remove a foreign body from the conjunctival sac of a friend, and Birch-Hirschfeld of a man who for months had milked a tuberculous cow. It may also be due to extension from neighboring parts of the lids or from the lacrimal gland. That tubercle of the conjunctiva is not more frequently seen in tuberculous individuals seems to prove that the disease is seldom metastatic, and that the conjunctiva is practically immune to contagion from within. Its frequency varies from 1 in 1,500 to none in 14,000, according to different observers. Groenouw says the conjunctiva is but little susceptible, as proved by the rarity of tuberculous disease in places where general tuberculosis is common. It appears in several forms, the miliary, ulcerative, disseminated, trachomalike tubercles, polypoid and as lupus. The symptoms are those of a mild form of chronic conjunctivitis. Its sequelæ are as disastrous as those of trachoma — entropion, ulcers, opacities, and pannus, perforation of the sclera, and extension of the destructive process to the lacrimal sac or to the interior of the ball.

Sämisch describes the usual appearance and progress of tuberculosis of the conjunctiva thus: "It consists in the beginning of an ulcerative process and then the development of small nodules (tuberculous) in a thickened conjunctiva in which the papillæ are hypertrophied." He adds: "But not always is the ulcerative stage present, but the tuberculous growth assumes the form of disseminated, small, deeply placed, irregularly defined nodules, which show but little inclination to become necrosed. In rare cases they appear as circumscribed, polyp-like prominences covered by a smooth surface, each one projecting above the level of the moderately injected and thickened conjunctiva."

The recent literature on ocular tuberculosis is voluminous. A small proportion only of the articles deals with tuberculosis of the conjunctiva. Sämisch's comprehensive article (Graefe and Sämisch, second edition) includes the references from 1864 to 1903.

The writers have agreed on the clinical signs and the diagnostic tests, but have differed as to the prognosis. Some patients recover spontaneously, many lose both eye and life, and a few have recovered after tuberculin injections. An example of the last is the case reported before this Section on October 17, 1905.

On August 18th the patient received in the arm 2 mm. of Mulford's tuberculin which was followed in thirty-six hours by prolonged general and local reaction. On September 2d a second injection with a still more marked and rapid improvement in the condition of the eyes. Five injections in all were given and on October 10th the nodules had disappeared and the eyes were quite well.

A positive opinion as to the value of tuberculin diagnosis and treatment cannot at this time be given, but I believe both to be of great service. Calmette's suggestion of applying the tuberculin directly to the conjunctival sac and then determining by the reaction the presence of tuberculosis is not in my limited experience dependable. It was tried in the case cited with negative result; also in fifteen or twenty individuals known to be suffering with general tuberculosis the reaction was present in only one fourth.

## CAUTERY CLAMP FOR HÆMORRHOIDS.

By DWIGHT H. MURRAY, M. D.,  
Syracuse, N. Y.

The use of the clamp and cautery in performing rectal operations for hæmorrhoids and other growths is so popular with surgeons that improvement in mechanism is always in order.

A hæmorrhoidal clamp should embrace the following qualifications in order that the work can be done securely and rapidly: 1. The most convenient form for most surgeons is shaped like a pair of scissors.

sors. 2. It is necessary that the clamp should have parallel jaws in order to securely hold all the tissues to be cauterized. 3. The clamp should be so constructed as to admit of rapid work. 4. One that can be easily taken apart for the purpose of sterilization. 5. A clamp that locks securely and automatically as it is closed. 6. It should be so made that the tissues can be released immediately. The fifth and sixth necessities mentioned are great time savers in an operation.

I feel that my clamp combines all of these qualifications for an instrument with which to work securely and rapidly. I claim originality only for the improvement this clamp embraces. The principle of the Goodell dilator reversed is used, and the same principle was used by Dr. Linthicum, of Baltimore, in his clamp six years ago. My improvement does away entirely with the thumb screw, which takes much time to close and open. I published the description of a clamp six years ago which was parallel jawed and scissors shaped, but find the new one to be a distinct improvement.

800 UNIVERSITY BLOCK.

## CAUSE OF PREMATURE SEPARATION OF THE PLACENTA.

By SAMUEL ROBINOVITZ, M. D.,  
Brooklyn, N. Y.

A number of times I have come across statements made by various contributors in the columns of the *New York Medical Journal* that the cause of premature separation of the placenta, in certain cases which they had reference to, was not known, or could not be definitely ascertained.

Now, I do not mean to imply that the cause of premature separation of the placenta in a given case can be determined with ease, nor that I can do so. Such a statement would seem absurd, and I would not venture to make it, considering the great number of predisposing and exciting causes enumerated in standard works on obstetrics. But having given this matter a thought I came to the following con-

clusion: I find that the most frequent and predominating cause that may be assigned to the premature separation of the placenta with more certainty is *traumatism*, in the form of either direct or indirect violence. To corroborate my statement, I beg to be permitted to relate my experience concerning this subject. During my obstetrical practice which I received since student life heretofore I have not observed such a number of cases where a too early separation of the placenta took place as I chanced to see during the past half a year. This is due to the fact that I was appointed, six months ago, a physician to a Woman's Confinement Society, in Brooklyn, the object of which society is to furnish gratis a physician or an accoucheur to all poor women who are to be confined, and apply for such aid, but have not adequate means requisite for the engagement of such an attendant. Hence, so far, in every case, without exception, where I found accidental hæmorrhage either before labor directly or during the last month of gestation I could elicit by close investigation (all such cases having been furnished me by the society) a history of traumatism as a cause. To make this more explicit I wish to maintain the fact, in support of my opinion, that several of the patients presented a history of having been beaten by their husbands—addicted to alcoholism, and being at the time under the influence of liquor—during the last trimester, or during the last month, because they refused to go to work for their husbands and furnish them with sufficient means for drink as they were able to during the earlier period of pregnancy. Again, others stated that they were thrown to the floor violently or had been pushed with their abdomen by their cruel husbands against a hard or solid object during the last period of pregnancy. Other such poor women told me that they fell from a flight of stairs, or met with some accident in the workshop or factory, where they were employed during pregnancy.

In conclusion I will state, therefore, that all these facts go to prove what an important part traumatism plays as a cause of accidental hæmorrhage or premature separation of the placenta, especially so when the woman is subjected to traumatism during the last month or two of the gestation period.

714 SUMNER AVENUE.

#### ACUTE PURULENT OTITIS MEDIA IN INFANTS AND YOUNG CHILDREN.\*

By ARTHUR J. IERZIG, M. D.,  
New York.

*Received for publication, December 1, 1904.*

Before proceeding with my subject I wish to report a few statistics of the prominence and frequency of the occurrence of acute otitis media during or following the acute exanthemata. Ducl's report in 1904 shows that there appeared in 6,000 cases of otitis media, about 10 per cent. in diphtheria, about 20 per cent. in scarlet fever, and about 5 per cent. in measles.

Ducroix and Gosselin reports 500 cases, of which acute purulent otitis media originated during simple

catarrh 29.4 per cent., measles 26.1 per cent., diphtheria 20 per cent., scarlet fever 12.6 per cent., pertussis 3 per cent., mumps 0.6 per cent., syphilis 1.6 per cent., and doubtful were 6.7 per cent.

Craiger (1891) reports 125 cases of acute purulent otitis media occurring in 1,000 cases of pneumonia.

Kerley in 1905 reports seventy-seven cases, one occurring with rubella, two with scarlet, seven with measles, and fifty-eight with influenza.

Of 248 cases examined and treated by me in five years in private practice there originated acute purulent otitis media during simple catarrh in 56 per cent., during measles in 14 per cent., during diphtheria in 2 per cent., during scarlet fever in 20 per cent., during pertussis in 1.5 per cent., during mumps in 0.5 per cent., and doubtful were 6 per cent. Eighty-nine cases, or 36 per cent., originated from the exanthemata; 230 cases, or 93 per cent., had adenoids; forty-eight cases, or 20 per cent., had hypertrophied tonsils; twenty-eight cases, or 11 per cent., had acute coryza, and twelve cases, or 5 per cent., had follicular amygdalitis.

Proportion of symptoms in 248 cases: 1, Rise of temperature was present in 248 cases, or 100 per cent.; 2, pain, and 3, tenderness in 114 cases, or 46 per cent.; 4, extreme restlessness in 236 cases, or 95 per cent.; 5, refusal of the child to rest its head upon the affected side in 125 cases, or 50 per cent.; 6, glandular enlargement in 189 cases, or 76 per cent.; 7, nasal discharge in 136 cases, or 54 per cent.; 8, gastroenteric symptoms in 69 cases, or 28 per cent., and 9, convulsions in 40 cases, or 16 per cent.

In these cases 50 per cent. showed the absence of pain or tenderness, which fact proves how uncertain the symptom of pain or tenderness is in infants and young children.

*Etiology.*—The following conditions may cause acute purulent otitis media: 1, The exanthemata; 2, adenoids; 3, hypertrophied tonsils; 4, acute coryza; 5, nasopharyngeal catarrh; 6, follicular amygdalitis; 7, hypertrophies of the turbinates, and 8, deflected septum. These causes act by either blocking the Eustachian tubes directly or by causing a congestion and thus closure of the tubes.

Closure of the tubes results in a disturbance of circulation in the middle ear and acts also as a good nidus for infection. I forget to mention that a frequent cause is the introduction of fluids into the tube by the use of the old fashioned nasal douche.

*Symptoms.*—These vary in infants and older children, hence I will describe them separately.

Infants.—These symptoms may be divided into Objective and Subjective. Objective symptoms are: 1. A red, angry, bulging drum membrane is seen upon careful examination. I also wish to state that very often one sees a bulging of the posterior portion of the tympanic membrane, or only the congestion of the upper third, and sometimes one only sees a congestion of Shrapnell's membrane alone. All of these lead to a diagnosis of acute otitis media. Very frequently a physician examines an ear and finds what appears to him a white membrane, which, if carefully and delicately swabbed, will reveal an angry, red, bulging ear drum. This white coating is caused by drugs used by the parents or doctor or by the secretion itself. Infiltration of the

canal wall occurs in infants, so that it is often impossible to introduce a small speculum, and so fail to see the ear drum.

Subjective symptoms are: 1, Temperature; 2, pain; 3, extreme restlessness; 4, refusal of infant to rest head upon affected side; 5, tenderness; 6, enlargement and tenderness of the glands under the angle of the jaw; 7, a nasal discharge; 8, symptoms of gastroenteritis, and 9, convulsions.

1. The temperature is one of the most reliable and constant symptoms that we have. If during the convalescence of an infant from one of the infectious fevers the temperature suddenly rises examine the ear, and you very frequently find the cause of the trouble here. Also in gastroenteric diseases, when the patient is improving, but the temperature remains high, examine the ear, and in 95 per cent. of the cases you will find an acute otitis media the cause of the temperature.

2. Pain is the most inconstant symptom we have in acute otitis media in infants. Kerley, 1901, reports seventy-seven cases, of which number there was a total absence of pain and tenderness in 69 per cent., and yet these infants all suffered from an acute otitis media. In cases where pain is present it is shown by the short, spasmodic cry of the infant, which is increased by pressure upon the auricle and in the angle of the lower jaw.

3. Extreme restlessness is a very constant symptom in infants, being present in over 90 per cent. of the cases. In cases of gastroenteritis we often see extreme restlessness as the only symptom of an acute otitis media.

4. Refusal of the child to rest its head upon the affected side was brought to notice by Dr. Marsh in 1897. This is not a constant sign, as it only appears in about 50 per cent. of cases.

5. I have already described tenderness upon pressure.

6. Enlargement of the glands under the angle of the jaw is fairly constant, as I have been able to collect 248 cases in my own experience where the glandular enlargement was present in 189 cases, or 76 per cent.

7. A nasal discharge was present in 136 cases of the 248 cases I have seen, or 54 per cent. This discharge is generally of a glairy mucoid character, but oftentimes mucopurulent.

8. Gastroenteric symptoms, such as diarrhoea and vomiting occur.

9. Convulsions occur in a small percentage of cases, and take the place of the chill, which we get in older children and adults.

Symptoms in older children are the same as those enumerated for infants, except that the element of pain plays a greater rôle than in infants, and is a far more constant symptom. Nausea is also a symptom often seen in older children. These children complain frequently of a fullness of the head. Anorexia is present in most of the cases in older children. In older children the gastroenteric symptoms are more marked than in infants. Headaches are also complained of.

#### Form of Cases

Cases in which the first symptoms are a high temperature, followed by a chill. The child has been exposed by the family doctor to summer complaint, or the mother

described it, but did not get well, the child being restless at night and eating poorly. The child also complained of pain in the ear, which the doctor told the mother was neuralgia. I asked the mother whether the doctor examined the child's ear and she told me "No, he did not think it necessary." Upon examination I found a bulging drum which I incised. There was an immediate relief of the gastroenteric symptoms, and the child was relieved of its summer complaint by an ear specialist as the mother termed it.

CASE II.—A child, six years of age, was brought to me by a physician for a running ear. He had treated the child for ten days for an enteritis, and suddenly on the eleventh day was surprised to see a discharging ear. The doctor tells me that the child complained of a stuffy feeling of the head, but he thought it was only a cold in the head, which the child contracted. The child had no pain whatsoever and this fact misled him. I am happy to say that the doctor now examines the ears of every child he has occasion to see.

These cases are only a few of the many that I have had the opportunity of seeing, and I always hear the same remark: "There was no pain, and I never thought of looking in the ear."

CASE III.—A typical case in an infant. An infant, three months old, did not nurse well, was restless at night, rested on one side continually, and cried when laid upon the opposite side. Rectal temperature 103° F. showed there was a slight discharge from the nose, and slight congestion of the pharynx and tonsils. After two or three days these symptoms subsided, but the infant continued to be restless and awoke frequently at night with a start. The child seemed quite ill, but no definite symptoms were present. Sometimes there was marked tenderness about the ear, and the child screamed when the ear was touched. After a few days a discharge was found in the external auditory canal and the symptoms subsided.

In some cases we get a rise in temperature and no other symptoms until the ear discharges, this being the first sign of the trouble in the ear. In other cases in older children the child hangs its head for several days, eats poorly, and does not sleep well; the child may complain of nausea, but no sign of a pain or a rise of temperature beyond 100° F. During the night the child is restless, and all of a sudden falls asleep, and the next morning we find a discharging ear and the child feels better and is brighter. Such is the general run of cases, and unless a physician examines the ears of such patients he will be misled very often as to the cause of the child's illness.

*Treatment.*—The treatment of acute purulent otitis media is summed up in three words, namely, *Remove the cause.* The treatment may be prophylactic; remove any postnasal obstruction, e. g., adenoids, hypertrophied tonsils, or treat the postnasal catarrh, which is present in a great number of children. A thorough examination of both ears in all children will become necessary. At the time the bulging drum is seen a paracentesis may be performed. After treatment consists in keeping the ear free from accumulated debris, by douching the ear with a hot normal saline solution every half hour. I prefer to have the people use a four ounce syringe. The Eustachian tube should never be inflated, as is the custom with a great many of our artists. When I open the ear drum I make a good free incision in the posterior quadrant, and carry my cut not only through the drum, but also well into the pericystic of the tympanic. A good free incision ought to relieve a patient in from one to three hours.

Keep your patient in bed upon a low plane until all the same symptoms have subsided. Douching with

a normal saline solution is all that is necessary, as the ear drains itself, and all we need to do is to remove the retained secretion which collects in the external auditory canal. A running ear will, under favorable conditions, be self limited in its course. The attack usually lasts from fifteen to thirty-six days. Keep the bowels open is an axiom to be followed in all febrile conditions, and so in purulent acute otitis media.

*Complications and Sequela* need only be mentioned, as my paper treats of acute purulent otitis media in infants and children. They may be: 1, Mastoiditis; 2, meningitis; 3, cerebral abscess; 4, thrombosis of the lateral sinus; 5, labyrinthine involvement, and, 6, facial paralysis.

*Conclusion.*—In summing up, I wish to state that my paper was not written with the idea of giving a complete résumé of this subject, but rather to bring to your notice the extreme importance of examining the ears of infants and children frequently, especially during the various exanthemata. The physician should not be satisfied with one examination of the ears, but make frequent and thorough examinations at short intervals. If I have made this clear to you this evening my purpose in presenting this paper shall have been fulfilled.

### Correspondence.

#### LETTER FROM OTTAWA.

*A Department of Public Health for Canada.—The Canadian Medical Association.*

OTTAWA, ONT., March 9, 1908.

On the 3d of March an important delegation of medical men, consisting of the medical members of the Canadian House of Commons, the medical men of the Senate, and the Special Committee on Public Health of the Canadian Medical Association, waited on Sir Wilfrid Laurier, the Prime Minister, and members of his cabinet to lay before them the various resolutions and reports which for the past six years have emanated from the Canadian Medical Association, as well as a memorandum on the subject of a Department of Health for Canada. At the present time the medical services in the Dominion government are administered from five separate departments, and the object is to have these consolidated into one department under one of the existing ministers of the crown. In the Department of Agriculture there are national quarantine, leprosy, etc.; in the Department of the Interior, diseased immigrants; in the Indian Department, sick Indians; in the Department of Marine, marine hospitals and sick seamen; in the Inland Revenue Department, the analyses of drugs and foods. The delegation was introduced by Dr. Black, M. P., of Windsor, N. S., and at his suggestion the Prime Minister called upon Dr. Lachapelle, chairman of the Quebec Board of Health and the convener of the Special Committee of the Canadian Medical Association on Public Health, to present a memorandum on the subject. This memorandum, in addition to calling for a consolidation of the above

mentioned services, also advocated a national laboratory for Canada, for the examination of vaccines, sera, etc. Dr. George Elliott, the general secretary of the Canadian Medical Association, came down from Toronto, and also addressed the cabinet, particularly as to what had been done by the national medical body in this direction. Dr. R. W. Powell, of Ottawa, who for five years was convener of this special committee, advocated the subject strongly, as did Lieutenant Colonel Carleton Jones, M. D., director general of the Canadian Army Medical Services; Dr. Schaffner, M. P., of Manitoba, and others. The Premier and the Hon. Minister of Agriculture were much impressed with the delegation, and considered the project feasible, but the Hon. Minister of Agriculture saw some difficulties in the way of bringing it to a successful issue. The matter is to be again debated in the House of Commons shortly, on the resolution proposed by Dr. Black a few weeks ago.

A very successful organization meeting was held in this city on the afternoon of the 3d of March, looking toward perfecting arrangements for the forty-first annual meeting of the Canadian Medical Association in this city on the 9th, 10th, and 11th of June. Dr. Montizambert, the Director General of Public Health, the president, called the meeting in his office in the Langevin Block, and a good representation of the physicians of Ottawa was present, as was the general secretary from Toronto. Dr. R. W. Powell, the chairman of the Committee of Arrangements, was in the chair, and after considerable discussion it was decided to follow out the arrangements provided for in the new constitution and inaugurate different sections for the meeting. There are to be general sections in medicine and surgery, and one session for each of the following sections: Eye, Ear, Nose and Throat; Obstetrics and Gynecology; Military Surgery; Public Health; Mental and Nervous Diseases.

### Therapeutical Notes.

**Chronic Sigmoiditis.**—Stern (*Medical Record*, February 29, 1908), in discussing the causal treatment of chronic sigmoiditis, says that sigmoidal spasm is readily amenable to atropine administered hypodermatically in repeated doses of 1/100 grain until relaxation of the affected parts has ensued. When the spasm is less pronounced, but occurs on the slightest provocation, lupulin should be given for its mild, enteric nervine sedative effects. In the motor neuroses of the sigmoidal segment of the colon, lupulin in the following combinations may, the author says, be found of service:

- I.  
 R Lupulin, ..... I.  
 Strontium bromide, ..... ãã 3ii.  
 M. ft. caps. No. 1.  
 Sig: Two capsules three to five times a day.
- II.  
 R Lupulin, ..... 3iiss;  
 Pulverized ipecacuanha, ..... gr. vi.  
 M. ft. cap. No. xx.  
 Sig: One capsule four to six times a day.

## MILK AND THE PUBLIC HEALTH.

Last week, in an article entitled *The Public Health and Marine Hospital Service*, we mentioned that the bureau's report of its investigation of the milk industry was announced as soon to be published. We have now received the report, a volume of 758 pages, styled *Milk and Its Relation to the Public Health*. Various writers have taken part in its production, and the result of their associated efforts is a most notable contribution to the literature of hygiene. The volume opens with an introductory article by Surgeon General Wyman. "It has been the object," says Dr. Wyman, "to include in this volume all available data showing the influence of milk as a carrier of infection, its chemical composition, the contaminations found therein, their influence upon it as an article of food, and the measures necessary in its production and handling to prevent such contamination." The surgeon general is conservative in his brief remarks on pasteurization. While he admits that it is "not the ideal to be sought," he declares that "practically it is forced upon us by present conditions." He goes on to say: "It prevents much sickness and saves many lives—facts which justify its use under proper conditions." These statements, it will be seen, do not justify the demand that has been made in some quarters for wholesale and indiscriminate pasteurization.

Passed Assistant Surgeon John W. Trask treats of milk as a cause of epidemics of typhoid fever, scarlet fever, and diphtheria. While perhaps the

text of the article tells us nothing new, it is written in a convincing and very readable style, and to it are appended about a hundred pages of tabular matter setting forth the facts with regard to epidemics believed to have been caused by milk. This statistical material, intelligently classified, must prove of great value. The milk supply of cities in its relation to the epidemiology of typhoid fever is treated of specifically by Passed Assistant Surgeon Leslie L. Lumsden, who considers not only milk itself, but also buttermilk, butter, cheese, and ice cream. His article is a short one, but it contains many useful reminders. Passed Assistant Surgeon John F. Anderson follows with a short report on the frequency of tubercle bacilli in the milk supplied to the city of Washington. He properly holds that all dairy cows should be tested with tuberculin, and those that respond to it so disposed of as to prevent their contributing to further milk supplies. Dr. Anderson furnishes us also with an interesting article on the relation of goat's milk to the spread of Malta fever.

Milk sickness, an affection apparently confined to the United States, is lucidly described by Passed Assistant Surgeon George W. McCoy. Dr. Charles Wardell Stiles treats briefly of the relation of cow's milk to the zooparasitic diseases of man. Under the title of *Morbidity and Mortality Statistics as Influenced by Milk*, Assistant Surgeon General J. M. Eager treats in rather a sketchy way of various points relating to milk and disease. He appears to believe implicitly in pasteurization, and he leaves the reader to infer that the diminution of mortality which followed the installation of a pasteurizing plant on Randall's Island in 1898 resulted solely from pasteurization. Dr. Harvey W. Wiley, chief of the Bureau of Chemistry of the Department of Agriculture, with the collaboration of Dr. George W. Stiles, of Washington, and Dr. M. E. Pennington, of Philadelphia, contributes an interesting and instructive article on ice cream. It has the crispness and directness of all of Dr. Wiley's writings. The great subject of the chemistry of milk is handled by Dr. Joseph H. Kastle, chief of the Division of Chemistry, and Assistant Surgeon Norman Roberts. It covers not only the chemistry of normal milk, but also the changes due to ferments and bacteria, milk poisoning, the chemical standards for the control of the sale of milk, and the adulterations of milk, together with a section devoted to the Washington milk supply.

Bacteria in milk receive the special attention of Dr. Milton J. Rosenau, the director of the Hygienic Laboratory, and the same author, in conjunction with Dr. McCoy, contributes an article on the germicidal property of milk. One of the conclusions is that "this so-called germicidal property of milk is

curs only in the fresh raw fluid." It seems to us rather important to bear this in mind in connection with the consideration of pasteurization. It is insisted that the action is rather "restraining" than truly germicidal. The significance of leucocytes and streptococci in milk is treated of by Assistant Surgeon William Whitfield Miller, and his essay, though brief, is full of interest. Dr. John R. Mohler, chief of the Pathological Division of the Bureau of Animal Industry of the Department of Agriculture, treats briefly but satisfactorily of the conditions and diseases of cows which affect their milk injuriously. Sanitary inspection is dealt with by Mr. E. H. Webster, chief of the Dairy Division of the Bureau of Animal Industry. His article, which is freely and effectively illustrated, brings out sharply the contrast between good and bad methods in the care and milking of cows, in the storage of milk, and in its transportation and distribution. The allied subject of sanitary water supplies for dairy farms is well handled by Dr. B. Meade Bolton, of the Bureau of Animal Industry, with a separate section on the water supplies of dairies supplying the District of Columbia. Dr. A. D. Melvin, the chief of the Bureau of Animal Industry, contributes a very short article on the classification of market milk. He thinks that all milk which comes from other than certified or inspected dairies should be pasteurized, though he appears to regard the process as only a substitute for more radical measures. Certified milk and infants' milk depots are succinctly described by Assistant Surgeon General John W. Kerr.

Pasteurization is particularly treated of by the director of the Hygienic Laboratory, Dr. Milton J. Rosenau, who balances the advantages and disadvantages of the procedure fairly. An excellent article on infant feeding is contributed by Passed Assistant Surgeon Joseph W. Schereschewsky. The volume concludes with an instructive article on the municipal regulation of the milk supply of the District of Columbia by Dr. William Creighton Woodward, the health officer of the District.

As in all variorum works, there is an unavoidable overlapping of subjects in this volume, but the collection as a whole is one that gives a renewed assurance of the efficiency of the Public Health and Marine Hospital Service, and must prove of great value in the final solution of the problems involved.

#### CALCIUM METABOLISM AND THE PARATHYREOIDS.

Of the many advances that have been made in medicine in the past twenty-five years, those concerned with the relations of specialized structures and metabolism have been the most striking. The discovery of thyroid insufficiency as a determining

factor in myxœdema and cretinism was but the first of a long series of observations that have served to unravel a large number of disorders dependent on thyroid inadequacy and thyroid excess.

The regulating effect of the adrenals in carbohydrate metabolism is a further illustration in the line of progress, and now we would call attention to a preliminary announcement of what promises to be a very important discovery by Dr. W. G. MacCallum and Dr. C. Voegtlin (*Johns Hopkins Hospital Bulletin*, March) that the parathyroids stand in close relation with the calcium metabolism of the body.

It will be recalled that Loeb and J. B. MacCallum showed that calcium salts had the property of reducing the irritability that caused twitchings in muscles rendered superactive by the application of other salts, notably those of potassium, and, further, that certain well recognized disorders, such as osteomalacia and rickets, usually associated with a defective amount of calcium, were frequently accompanied by a muscular irritability sufficient in many cases to cause what is clinically grouped as tetany.

With these general facts in mind, and further recalling that an abundant milk diet, which is rich in calcium, served to either prevent the tetany reaction in parathyroidectomized dogs, or to greatly mitigate its severity, the authors were led to a study of the calcium metabolism in animals in which tetany had been produced by removing the parathyroids.

They tell us that all the violent symptoms produced by extirpating these glands—muscular twitching and rigidity, tachypnoea, fibrillary tremors, increased rapidity of the heart beat, etc.—may be almost instantly cured by the intravenous injection of a calcium salt. They use the acetate or lactate for the purpose by hypodermic injection, or, acting more slowly, by the stomach. Magnesium salts are also efficient, but they introduce a toxic action, while potassium salts make things worse. It is significant that an analysis of the blood taken from a dog during tetany shows an amount of calcium which is only about half that of a normal dog on the same constant diet.

The authors suggest the hypothesis that the parathyroids control in some way the calcium metabolism, so that upon their removal a rapid excretion, possibly associated with inadequate absorption and assimilation, deprives the tissues of calcium salts. The certainty and rapidity with which the symptoms of tetany are dispelled by the administration of calcium salts make it seem probable that this observation will have some therapeutical importance, not only in postoperative tetany, but also in the vari-

ous forms of tetany which occur spontaneously in children and in connection with infectious diseases, pregnancy, and lactation. They suggest that it is possible that the tetany of lactation may be due to the great drain of calcium in the production of milk rich in calcium, especially in individuals in whom there is parathyroid insufficiency.

The analogies of the modifications of carbohydrate metabolism by the destruction of the islands of Langerhans, with the production of diabetes mellitus, suggest the term diabetes calcareus for this type of phenomena. The work is not without immense significance when one views the entire group of motor anomalies, the choreas, catatonias, tics, and it may be even epilepsy, which may have some light thrown on them through this newly opened door.

### THE CRIPPLED AND DEFORMED CHILDREN OF THE STATE OF NEW YORK.

In West Haverstraw there is an old wooden Colonial mansion which has been remodeled as thoroughly as was practicable to serve as the New York State Hospital for the Care of Crippled and Deformed Children. The old building happened to stand on a tract of land, fifty acres in extent, which the State bought in 1904 as a site for a large new hospital which it evidently intended to build, and in the interest of economy it was thought expedient to use the building as a temporary hospital. But it is not well adapted to the purpose. In the first place, it is too small, for it will accommodate only forty-five patients, though at times there have been forty-eight within its walls. It cannot be enlarged to advantage, but there is a crying need for more extensive provision for the cure (which is often possible) of children who, but for such an institution, would either die or grow up more or less incapacitated for work and become a burden to the State for life. Therefore a bill has very properly been introduced into the present legislature to appropriate \$100,000 for building and equipping on the West Haverstraw site a modern hospital with accommodations for two hundred patients, the ultimate design being to enlarge it to double that capacity.

In the mean time the Medical Society of the State of New York has passed a resolution, apparently not very well considered, approving of a project to convert into a similar hospital certain unoccupied buildings in Rochester formerly used by the State as a custodial and correctional asylum for boys. This it is pointed out that the Rochester buildings also are unsuitable for the purpose, and that to carry out the proposed plan would be to scatter forces which ought to be concentrated. The West Haverstraw institution already has the special appliances for the work

in hand, and to duplicate them in Rochester would be to spend money unnecessarily. It seems better to establish and support one adequate hospital for the relief of deformity than to start two that will still fall short of answering the purpose, though doubtless in years to come others will be needed. The objection that West Haverstraw is not easily reached by the poor of the entire State is met by the statement that the railway companies whose lines lead to that point have heretofore shown themselves willing to furnish free transportation to children accepted as patients, and would probably continue to do so. It appears to us, therefore, that in the interest of economy the State would do well to perfect the hospital already in existence rather than to establish another imperfect one. The action taken by the Medical Society of the State of New York shows that the profession recognizes the need of a suitable provision for the treatment of crippled and deformed children, but its specific recommendation hardly seems wise in view of the situation which we have outlined.

### THE CONGESTION OF POPULATION IN NEW YORK.

On last Monday night an exhibit illustrating the congestion of population in New York and its moral, intellectual, and physical effects was opened in the American Museum of Natural History with a formal address by the governor of the State. Many who attended were surprised to find that the large auditorium of the museum was filled, a fact which we should like to construe as being a hopeful indication of the attitude of the public on this most important question, though it is quite possible that an opportunity to hear the governor had some bearing on the size of the audience. Such as had the privilege of attending the conference cannot but have been impressed with the grave responsibilities which rest upon the shoulders of the executive authorities in dealing with a problem which is so full of serious import for the future, not only of the city and State of New York, but of the republic. Governor Hughes might well be both oppressed and depressed, as he admitted, by the exhibit, for there are shown in graphic manner the density of the congestion in various parts of New York and the pitiable results arising from it, results which, as Governor Hughes rightly said, "are intolerable. They cannot last."

This exhibit is the first step in a systematic study of the evils of congestion, and should furnish a basis for suggestions as to the means of relieving these evils. The committee which organized the exhibit is to be congratulated upon its wisdom in pointing out from the exhibition a certain phase or phases of the evils which they point out. The function which the committee has assumed is that of making clear

the need for the amelioration of the congestion of population and its attendant evils. There naturally will be differences of opinion as to the best means of preventing the continuance of these conditions, and if the committee had come before the public at this juncture with a full fledged plan of reformation, their energies would probably have been dissipated in the discussion of details of such plans. Instead of doing this, the members have wisely restricted their efforts, so far as this conference is concerned, to a presentation of the facts, with a view to so arousing the public conscience to its responsibilities in the matter as to lead the way to a systematic study of ways and means of changing these conditions.

The physician is necessarily interested in this topic, for so long as these densely congested areas of population exist in our large cities, just so long will it be impossible to give protection against infectious disease and insure the normal, healthy growth of the children of the slums, who in the near future will constitute the men and women of the republic. A child reared under such conditions as are portrayed in some parts of this exhibit is almost foredoomed to ill health and immorality. Physicians more than the people of any other class are keenly alive to the degrading influences, both physical and moral, incident to living under the unhygienic conditions to which the very poor of the city of New York are condemned, and if this exhibit can stimulate the physicians who may visit it to a keener appreciation of the responsibility under which they rest for the creation of public sentiment against such abuses as are shown, it will have done good work, bearing fruit in improved conditions of living and higher types of manhood for our future citizens. Every physician who can do so should visit this exhibit, which will be open for two weeks, and should use it as a means of stimulating public interest in a question which is one of the most vital importance to the future welfare of the community and of the nation.

#### A PUERILE ATTEMPT AT HUMOR.

On Friday of last week, under the subheading of Hospital Ship Will Join Fleet Fully Equipped, the *New York Times* published a special dispatch from Washington, of which the following is the substance:

With its magazines stored with pills, and high explosive scidlitz powders in its handling room, within easy reach of the ammunition hoists, the hospital ship *Relief* will set sail from San Francisco under orders from the Navy Department to join Admiral Evans's fleet at Magdalena Bay. In consequence Rear Admiral Surgeon Stokes will steam south with the muzzles of his medicine bottles uncapped and his crew of internes in readiness for whatever may arise.

This precious piece of puerility could not be held

back for the mail; it had to be telegraphed! We congratulate the *Times* on the humor of its correspondent.

#### THE BUREAU OF ANIMAL INDUSTRY.

The *Twenty-third Annual Report of the Bureau of Animal Industry* for the year 1906, recently issued, is chiefly devoted to matters of interest from the agricultural point of view and from that of persons concerned with meat products, but it contains also much that will prove valuable to medical men. We have had frequent occasion to cite the bureau's publications, nearly all of which are of the greatest scientific or economic value.

#### Obituary.

DANIEL B. ST. JOHN ROOSA, M. D., LL. D.,  
of New York.

Dr. Roosa died suddenly on Sunday, March 8th, lacking less than a month of the age of seventy years. He had appeared to be in his usual good health, but it is now understood that he had trouble with the kidneys and with the heart. Soon after his morning bath he fell to the floor and was dead almost at once. He was a native of Bethel, Sullivan County, N. Y. He received his medical degree from the Medical Department of the University of the City of New York in 1860. After taking the full course of two years on the surgical house staff of the New York Hospital, he made a special study of ophthalmology in Vienna and Berlin. Returning to New York, he entered upon ophthalmic practice and soon won distinction in that field, both as a practitioner and as a teacher.

Dr. Roosa was a born leader of men. Had he chosen a purely political career, he would undoubtedly have climbed very high. As it was, he was able to move the general body of the medical profession almost at will by the earnestness and precision of his oratory. His was the central figure in the movement which led to the abolition of the old Code of Ethics in the State of New York. And it was not in speechmaking alone that he made himself felt; he was a skilled organizer, as was shown by his establishment of the New York Postgraduate Medical School and Hospital, the first institution of its kind. Almost everybody looked for the failure of the scheme, but Dr. Roosa carried it through triumphantly. He was a man of great mental and moral strength.

EDWARD C. WYMAN, M. D.,  
of Detroit.

This distinguished surgeon died at his home, in Detroit, on Monday, March 9th, after a short illness. He was fifty-six years old. He was a native of Indiana, but had practised in Detroit for many years. He was a frequent contributor to medical literature and a well known authority on abdominal surgery. He was an attractive man personally and a highly successful practitioner.

## News Items.

**Changes of Address.**—Dr. Henry Mitchell Smith, to 64 Montague street, Brooklyn, N. Y.

**The Franklin Institute of Philadelphia** has received \$50,000 from Mrs. Anne Weightman Walker Penfield as a memorial to her father, the late William Weightman.

**Portland, Me., Medical Club.**—At a meeting of this organization held on Thursday, March 5th, Dr. Willis B. Moulton read a paper entitled *Laboratory versus Clinical Diagnosis*.

**Dr. R. V. Wagner, of Chicago**, inventor of apparatus for the therapeutical application of electricity, and head of the firm of R. V. Wagner & Co., died on Thursday, March 12th.

**Gloucester County, N. J., Medical Society.**—The next meeting of this society will be held in Woodbury, N. J., on Thursday, March 19th, at 1:30 p. m. A full attendance of the members is desired.

**Donations to Charities.**—Mrs. Anne Weightman Walker Penfield has given \$20,000 to the Society to Protect Children from Cruelty in Philadelphia and \$20,000 to the Society for the Prevention of Cruelty to Animals in Philadelphia.

**A Hospital and Medical School in Manchuria.**—The Chinese authorities have announced their intention of establishing in Kirin, Manchuria, a medical school and hospital, with graduates from the Medical School of Formosa as teachers.

**The Frankford Hospital, of Philadelphia.**—The new buildings of this hospital were dedicated on the afternoon of Tuesday, February 25th. Dr. B. F. Walters and Dr. Samuel Bolton made addresses. Donation Day was also observed.

**Society of Medical Jurisprudence, New York.**—The two hundred and twelfth regular meeting of this society was held on March 9th. The paper of the evening was read by A. Delos Kneeland, Esq., of the New York bar, on *Honesty in Our Professions*.

**The Pennsylvania State Board of Pharmaceutical Examiners** has issued certificates to 8 registered pharmacists and 40 qualified assistants, as a result of the examinations held in Harrisburg on February 15th. One hundred and thirteen persons took the examinations.

**The Clinical Society of the Elizabeth, N. J., General Hospital** will hold its next meeting at the hospital on Tuesday, March 17th, at 9:00 p. m. Dr. T. N. McLean will read the paper of the evening on *Epidemic Influenza*. Dr. Russell A. Shirrefs is the secretary of the society.

**Rochester, N. Y., Academy of Medicine.**—At a meeting of this academy, which was held on March 11th, the evening was devoted to general observations and conclusions after a visit to Dr. William J. Mayo and Dr. Charles H. Mayo, of Rochester, Minn., by Dr. Zimmer and Dr. Elsner.

**St. Catherine's Hospital, Brooklyn.**—At the annual meeting of the medical board of this hospital, which was held recently, the following officers were elected: President, Dr. Maurice Enright; vice president, Dr. Peter Hughes; secretary and treasurer, Dr. E. J. Carroll; and member elect to executive committee, Dr. J. C. Kennedy.

**New York Pathological Society.**—The regular meeting of this society was held at the New York Academy of Medicine on Wednesday evening, March 11th. The programme included a paper by Dr. Leo Berger, entitled *The Pathology of the Muscles in Cases of Gravel of the Lower Extremity*, and a paper by Dr. J. C. Spencer, entitled *Gravel of the Lower Extremity*.

**Buffalo Academy of Medicine.**—The regular meeting of the Society of Medicine was held at the Buffalo Academy of Medicine on Wednesday evening, March 11th. The programme included a paper by Dr. J. C. Spencer, entitled *The Pathology of the Muscles in Cases of Gravel of the Lower Extremity*, and a paper by Dr. J. C. Spencer, entitled *Gravel of the Lower Extremity*.

**The Pathological Society of Philadelphia.**—At a meeting of this society, which was held on March 11th, the evening was devoted to general observations and conclusions after a visit to Dr. William J. Mayo and Dr. Charles H. Mayo, of Rochester, Minn., by Dr. Zimmer and Dr. Elsner.

Wolf; Dr. R. S. Lavenson read a paper on *Acute Lymphopenic Lymphatic Leucæmia*; and Dr. J. L. Donnhauser read a paper on *Splenomegaly*.

**A Physicians' Protective Association in Gloucester County, N. J.**—The physicians of Woodbury, Mantua, Wenonah, and Westville have organized a protective association, the members of which embrace all practising physicians in the towns named. The association meets on the first Wednesday evening of each month at the residence of the members in turn.

**Société de Pathologie Exotique** is the name of a new medical society which has just been organized in Paris which will meet at the Pasteur Institute. The principal object of the society will be the study of tropical diseases in man and animals, and the sanitary measures that will best prevent the spread of epidemics of diseases of exotic origin. Dr. Laveran is the president of the society.

**The Long Island Society of Anæsthetists** will hold its spring meeting on Saturday evening, March 14th, in the building of the Medical Society of the County of Kings, 1313 Bedford avenue, Brooklyn. The evening will be devoted to a consideration of modern European methods of surgical anæsthesia, and all members of the profession who are interested in the subject are invited to be present.

**College of Physicians of Philadelphia.**—On Monday evening, March 9th, a meeting of the Section in General Medicine was held, and the following papers were read: *The Resistance of Diabetics to Bacterial Infections*, by Dr. J. C. Da Costa, Jr., and Dr. J. G. Beardsley; *Some Cases of Fever of Obscure Origin*, by Dr. J. Dutton Steele; and *A Case of Typhoid Fever Usurped in by an Attack of Uremia*, by Dr. R. Max Goepf.

**The Northern Medical Association of Philadelphia** held a meeting on Friday evening, February 13th. The general subject for discussion was gonorrhœa, and papers were read as follows: *The Symptomatology and Treatment of Gonorrhœa*, by Dr. H. M. Christian; *The Symptomatology and Diagnosis of Complications of Gonorrhœa*, by Dr. Alexander A. Uhle; and *The Treatment of the Complications of Gonorrhœa*, by Dr. William H. MacKinney.

**Richmond, Va., Academy of Medicine and Surgery.**—A regular meeting of this academy was held on the evening of March 10th. The programme included a paper on *Brain Lesions secondary to Diseases of the Eye, Ear, and Nose*, by Dr. Clifton M. Miller, and a paper entitled *An Improved Operation for Mastoid Disease*, by Dr. D. A. Kuyk. Dr. Miller's paper was discussed by Dr. John Dunn, and Dr. Kuyk's paper was discussed by Dr. William F. Mercer.

**Geneva, N. Y., Medical Society.**—At the regular monthly meeting of this society, which was held on Thursday evening, March 5th, the general subject for discussion was constipation. Many interesting papers were read, and at the close of the meeting refreshments were served. The officers of the society for the present year are: President, Dr. J. H. Knickerbocker; vice president, Dr. C. C. Lytle; treasurer, Dr. C. F. Nieder; and secretary, Dr. J. A. Spengler.

**Meetings of German Medical Societies.**—The seventh annual congress of the German Society for Orthopaedic Surgery will be held in Berlin on Saturday, April 25th; the fourth annual congress of the German Röntgen Ray Society will be held in Berlin on Sunday, April 26th, and the thirty-seventh annual congress of the German Surgical Society will be held in Berlin on April 21st to 24th. Exhibitions of instruments and apparatus will be held in connection with these congresses.

**Philadelphia Neurological Society.**—At a stated meeting of this society, which was held on March 11th, the evening was devoted to general observations and conclusions after a visit to Dr. William J. Mayo and Dr. Charles H. Mayo, of Rochester, Minn., by Dr. Zimmer and Dr. Elsner. The programme included a paper by Dr. Leo Berger, entitled *The Pathology of the Muscles in Cases of Gravel of the Lower Extremity*, and a paper by Dr. J. C. Spencer, entitled *Gravel of the Lower Extremity*.

**The Düsseldorf Postgraduate Medical School.**—Professor Witzell, president of the new Postgraduate Medical School at Düsseldorf, Germany, has issued an interesting prospectus showing the course of instruction given. The corps of teachers includes several men of prominence in the medical world, and, as the course is particularly intended for postgraduate students, it may interest our readers to know that foreign physicians, including those from America, of course, are admitted to this school without any fee except the registration fee of \$1 each.

**The Medical Society of the Borough of the Bronx** held a stated meeting on Wednesday, March 11th. Dr. Ralph Waldo read a paper entitled *The Indications and Contraindications for the Use of the Uterine Curette*, and Dr. Malcolm McLean read a paper entitled *A Consideration of the Fœtal Envelopes in Obstetrics*. The officers of the society for the current year are: President, Dr. William McChristie; first vice president, Dr. Edward Broquet; second vice president, Dr. Charles Graef; secretary, Dr. Clarence H. Smith; and treasurer, Dr. William H. Meyer.

**Medical Society of the County of Richmond, N. Y.**—The regular monthly meeting of this society was held at the Staten Island Academy of Medicine on Wednesday evening, March 11th. Dr. Carl Keppler, of Manhattan, read a paper on the Treatment of Infantile Paralysis, which was discussed by Dr. Sprague and Dr. Johnston, and Dr. A. P. Voislowsky, of Manhattan, read a paper on Oral and Nasal Troubles in General Practice, which was discussed by Dr. Coonley and Dr. Jessup. Dr. C. E. Pearson, of 32 Central avenue, New Brighton, S. I., is the secretary of this society.

**Vacancies in the House Staff of the New Harlem Hospital.**—A competitive examination to fill vacancies in the house staff of the new Harlem Hospital, which is situated at the corner of Lenox avenue and One Hundred and Thirty-sixth street, will be held at the hospital on Saturday, March 21st, commencing at 10 a. m. Applications, stating the name, address, academic education, place and date of graduation or expected graduation in medicine, of the applicant, and accompanied by at least three letters of endorsement from regular physicians in good professional standing, should be sent by mail to Dr. R. Van Santvoord, to West One Hundred and Twenty-second street.

**Philadelphia County Medical Society.**—The Central Branch of this society held a meeting on Wednesday, March 11th, the general subject for discussion being *nostrums and nostrum prescribing*. Papers were read by members of the pharmaceutical profession, as follows: *Nostrum Prescribing: Its Cure*, by Prof. Joseph P. Remington; *Nostrums in Dosage Form*, by Mr. M. I. Wilbert; *The Relative Frequency in the Prescribing of Proprietary Medicines*, by Mr. Ambrose Hunsberger; and *The Legal Safeguards Surrounding U. S. P. and N. F. Preparations*, by Mr. W. L. Cliffe. The discussion was opened by Dr. James M. Anders and was participated in by many prominent members of the medical profession.

**Eastern Medical Society of the City of New York.**—At a meeting of this society, which was held on Friday, March 13, Dr. D. A. Singer presented a case of acetonuria bradycardia. There was a further discussion of the papers on diseases of the bones and joints which were read at the previous meeting of the society, and Dr. A. J. Herzog gave a short résumé of the commoner conjunctival and corneal diseases, which was discussed by Dr. Ervin Jörök and Dr. Martin Cohen. Dr. Henry S. Stark read a paper entitled *Diabetes and the Food Factor*, which was discussed by Prof. Lafayette B. Mendel, of Yale University; Prof. Graham Lusk, of Bellevue; Dr. Max Einhorn, Dr. W. Gilman Thompson, Dr. J. Kaufmann, Dr. Phœbus A. Levene, and Dr. Morris Margenau.

**Statistics Desired on Gallstone Surgery.**—Dr. Hans Kehr, of Halberstadt, Germany, has been designated as reporter on the surgery of gallstones at the International Congress of Surgeons, which will be held in Brussels next September. He wishes to collate as complete statistics as possible, and to that end requests that all surgeons who have had any experience in this direction will send him complete statistics of their own cases covering the five years from 1903 to 1907, inclusive. He would like to have the cases arranged in three classes: 1st, pure stone cases; 2d, complicated, benignant and reparable cases; 3d, complicated, malignant and irreparable cases, the statistics re-

to learn from surgeons who can furnish such statistics what their views are regarding the various operative methods.

**Entertainment for Women Physicians Attending the Chicago Meeting of the American Medical Association.**—The Women's Alumnae Committee, the Women's Medical Society of the State of Illinois, and the Women's Medical Club of Chicago, announce that a banquet and entertainment will be given on the evening of June 2d, to which all women physicians who are in Chicago at that time are cordially invited. Each of these organizations desire to entertain the visitors, but as the session is very short they have decided to join forces. At the banquet a special feature will be the reunions of the alumnae of the different colleges. The College Club in the Fine Arts Building, 203 Michigan avenue, will be at the disposal of the women physicians exclusively during the meeting.

**Philadelphia Pædiatric Society.**—At a regular meeting of this society, held on March 10th, the following programme was presented: Dr. James K. Young exhibited a case of tuberculous dactylitis; Dr. James K. Young reported a case of streptococcic dactylitis; Dr. C. F. Judson and Dr. H. L. Carncross reported a case of encephalitis; Dr. E. Buryville-Holmes read a paper entitled *Lumbar Puncture, its Technique and the Value of Cytodagnosis in Differentiating the Tuberculous from the Epidemic Form of Meningitis*; Dr. C. H. Muschlitz read by invitation a paper on *Congenital Unilateral Hypertrophy*; Dr. B. F. Royer and Dr. J. D. Wilson reported a case of incomplete heterotaxy with unusual heart malformations; and Dr. C. F. Judson and Dr. W. N. Bradley presented a case of sporadic cretinism.

#### Scientific Society Meetings in Philadelphia for the Week Ending March 21, 1908:

MONDAY, March 16th.—Northeast Branch Philadelphia County Medical Society.

TUESDAY, March 17th.—Dermatological Society; Academy of Natural Sciences; North Branch, Philadelphia County Medical Society.

WEDNESDAY, March 18th.—Section in Otology and Laryngology, College of Physicians; Association of Clinical Assistants of Wills Hospital; Franklin Institute.

THURSDAY, March 19th.—Section in Gynecology, College of Physicians; Section Meeting, Franklin Institute; Medical Society of the Woman's Hospital; Section in Ophthalmology, College of Physicians.

FRIDAY, March 20th.—University of Pennsylvania Medical Society; American Philosophical Society.

#### Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Department of Health for the following statement of new cases and deaths reported for the two weeks ending March 7, 1908:

	February 26—		March 7—	
	Cases.	Deaths.	Cases.	Deaths.
Tuberculosis, pulmonalis	451	294	470	200
Diphtheria	373	44	379	48
Measles	1,554	89	1,495	26
Scarlet fever	924	79	901	56
Smallpox	—	—	—	—
Varicella	80	—	113	—
Typhoid fever	15	3	26	7
Whooping cough	20	1	0	1
Cerebro-spinal meningitis	16	8	100	32
<b>Totals</b>	<b>3,503</b>	<b>334</b>	<b>3,402</b>	<b>350</b>

**Personal.**—Surgeon General Baron Sato has been appointed president of the Great Korean Hospital, attached to the Japanese Residency-General in Seoul.

Dr. W. C. McKechnie, of Portland, Ore., Dr. John J. Snyder, and Dr. George C. Thomas, U. S. Navy, are registered at the Philadelphia Polyclinic and College for Graduates in Medicine.

Dr. Roswell P. Angier, of the Medical College of Yale University, has been promoted to an assistant professorship of psychology.

It is reported that Dr. August Martin, professor of gynecology at the University of Griefswald, will visit the United States during the summer, and will attend the meeting of the American Medical Association.

Dr. R. C. Kemp announces that he has moved from Echo, La., to Baton Rouge, La., where he has an office in the Raymond Building.

**The Mortality of Chicago.**—According to the report of the Department of Health for the week ending February 29th, there were during the week 677 deaths from all causes, as compared with 786 for the corresponding week in 1907. The annual death rate was 16.30 in 1,000 of population, as compared with an annual death rate of 19.45 for the corresponding week in 1907. The principal causes of death were: Apoplexy, 10; Bright's disease, 43; bronchitis, 25; consumption, 71; cancer, 26; convulsions, 4; diphtheria, 15; heart diseases, 73; influenza, 24; intestinal diseases, acute, 39; measles, 6; nervous diseases, 21; pneumonia, 106; scarlet fever, 9; suicide, 8; typhoid fever, 6; violence, other than suicide, 25; whooping cough, 4; all other causes, 162.

**The Health of Philadelphia.**—During the week ending February 22, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Typhoid fever, 183 cases, 32 deaths; scarlet fever, 80 cases, 4 deaths; chickenpox, 41 cases, 0 deaths; diphtheria, 78 cases, 11 deaths; measles, 172 cases, 4 deaths; whooping cough, 36 cases, 6 deaths; pulmonary tuberculosis, 181 cases, 76 deaths; pneumonia, 113 cases, 77 deaths; erysipelas, 17 cases, 0 deaths; puerperal fever, 2 cases, 8 deaths; mumps, 27 cases, 0 deaths; cancer, 14 cases, 17 deaths. The following deaths were reported from other transmissible diseases: Tuberculosis, other than tuberculosis of the lungs, 5; malarial fever, 1; dysentery, 1; diarrhoea and enteritis, under two years of age, 15. The total deaths numbered 590, in an estimated population of 1,532,733, corresponding to an annual death rate of 20.00 in 1,000 of population. The total infant mortality was 118; under one year of age, 95; between one and two years of age, 23. There were 43 still births; 30 males, and 13 females.

#### Society Meetings for the Coming Week:

**MONDAY, March 16th.**—New York Academy of Medicine (Section in Ophthalmology); Medical Association of the Greater City of New York; Hartford, Conn., Medical Society.

**TUESDAY, March 17th.**—New York Academy of Medicine (Section in Medicine); Medical Society of the County of Westchester, N. Y.; Buffalo Academy of Medicine (Section in Pathology); Triprofessional Medical Society of New York; Medical Society of the County of Kings N. Y.; Binghamton, N. Y., Academy of Medicine; Clinical Society of the Elizabeth, N. J., General Hospital; Syracuse, N. Y., Academy of Medicine; Ogdensburg, N. Y., Medical Association.

**WEDNESDAY, March 18th.**—New York Academy of Medicine (Section in Genitourinary Diseases); New York Society of Dermatology and Genitourinary Surgery; Woman's Medical Association of New York City (New York Academy of Medicine); Medicolegal Society, New York; New Jersey Academy of Medicine (Jersey City); Buffalo Medical Club; New Haven, Conn., Medical Association; New York Society of Internal Medicine; Northwestern Medical and Surgical Society of New York.

**THURSDAY, March 19th.**—New York Academy of Medicine; German Medical Society, Brooklyn; Newark, N. J., Medical and Surgical Society; Æsculapian Club of Buffalo, N. Y.

**FRIDAY, March 20th.**—New York Academy of Medicine (Section in Orthopædic Surgery); Brooklyn Medical Society; Clinical Society of the New York Postgraduate Medical School and Hospital; East Side Physicians' Association of the City of New York; New York Microscopical Society.

**The Medical Association of the Greater City of New York** will hold its annual meeting in the Baus Hall, New York Academy of Medicine, on Monday, March 16th, at 3.30 p.m. The program will be devoted to a discussion of the subject of progress in bacteriology, and papers will be read as follows: The Relations of Tubercle and Paratubercle, by Dr. J. Ramsay Hunt; Laryngeal Involvement in Tuberculosis, by Dr. W. H. Stettin; The Bacteriology of Dr. J. Bentley Squier, Jr.; Present Methods of Treatment, by Dr. S. Wachsmann. Among those who will take part in the general discussion are Dr. A. D. Rockwell, Dr. Frederick Peterson, Dr. W. B. Pritchard, and Dr. Joseph Fraenkel. The officers of the society for the present year are: President, Dr. Robert T. Morris; vice president, Dr. Raymond F. Van Gieson; recording secretary, Dr. P. H. Berg Porter; corresponding secretary, Dr. Frank C. Ray-

nor; treasurer, Dr. A. Ernest Gallant; chairman for the Borough of Manhattan, Dr. J. Blake White; chairman for the Borough of the Bronx, Dr. Nathan B. Van Etten; chairman for the Borough of Brooklyn, Dr. J. Scott Wood; chairman for the Borough of Queens, Dr. Neil Orrin Fitch; chairman for the Borough of Richmond, Dr. Henry C. Johnston.

**Scholarships and Fellowships at the Rockefeller Institute.**—The Rockefeller Institute for Medical Research announces that for the year 1908-1909 a limited number of scholarships and fellowships will be awarded for work to be carried on in the laboratories of the institute in New York City, under the following conditions: The scholarships and fellowships will be granted to assist investigations in experimental pathology, bacteriology, medical zoology, physiology and pharmacology, physiological and pathological chemistry, and experimental surgery. They are open to men and women who are properly qualified to undertake research work in any of the above mentioned subjects, and are granted for one year. The value of these scholarships and fellowships ranges from \$800 to \$1,200 each. It is expected that holders of the scholarships and fellowships will devote their entire time to research work. Applications accompanied by proper credentials should be in the hands of the secretary of the Rockefeller Institute not later than April 1st. The announcement of the appointments is made about May 15th. The term of service begins preferably on October 1st, but, by special arrangement, may be begun at another time. Dr. L. Emmet Holt, 44 West Fifty-fifth street, New York, is the secretary.

**The Congestion of Population in New York.**—The exhibit of congestion of population in New York, which will be shown for two weeks at the American Museum of Natural History, Seventy-seventh street and Columbus avenue, was formally opened to the public on Monday evening, March 9th, by a series of addresses, the principal speaker of the evening being the Governor of the State. Governor Hughes's address was devoted to an accentuation of the importance of the work being done by the conference and of the need of a careful, systematic survey of the field in just the way in which it was being carried on by the Committee on Congestion of Population. He said that the exhibit was a most depressing one, and a study of it would be helpful in arousing public sentiment to the need of proper legislative regulation of the various and complex problems involved and the need of proper enforcement of such legislation. He took a hopeful view as to the possibility of eradicating the evils incident to this congestion, now that they are being carefully and scientifically studied. He said that he felt confident that with the immense mass of facts and statistics which had been collated through the agency of the committee, it would be possible eventually to devise some means of ameliorating the evils which are so vividly portrayed in the exhibit. The meeting was opened by Mrs. Vladimir G. Simkovitch, chairman of the Committee on Congestion of Population, who, after a brief address, introduced Dr. John H. Finley, president of the College of the City of New York, who presided during the meeting. The speakers included Count Massaglia, the Italian Consul General, who spoke on behalf of Baron des Planches, the Italian Ambassador, who was unable to attend; Dr. Baker, representing the Commissioner of Health of New York; the Hon. Robert W. Heberd, Commissioner of Public Charities of New York, and Mr. Jacob A. Riis. Further conferences were held throughout the day and evening of Tuesday, Wednesday and Thursday. The speakers at these meetings include the following: Mr. Gaylord S. White, Dr. George W. Goler, of Rochester, N. Y.; Mr. Joseph Lee, of Boston; Mr. Howard Bradstreet, Mr. Robert Bruere, Dr. Arthur Shoemaker, Mr. Robert Watchorn, Dr. Lee K. Frankel, Mr. Leonard B. Robinson, Dr. Antonio Stella, Mr. Gino C. Speranza, Miss Amy A. Bernardy, of Smith College; Professor Morris Loeb, Mr. Eugene A. Philbin, Dr. Felix Adler, Dr. E. R. L. Gould, Dr. Henry M. Leipziger, Mr. Homer Folks, Mr. Mornay Williams, Miss Mary Van Kleeck, Miss Julia Richman, Dr. Edward P. Devine, Mrs. Florence Kelley, Dr. Henry R. Seager, Dr. Walter Laidlaw, Mr. John F. Tobin, Mr. George Neubert, Dr. William H. Allen, Professor L. H. Bailey, of Cornell University; Dr. Abraham Jacobi, Mr. C. W. Larmon, Professor Jeremiah W. Jenks, of Cornell University; Mr. Charles Mulford Robinson, of Rochester, N. Y.; Mr. Lawson Purdy, and the Rev. Stephen S. Wise.

## Pith of Current Literature.

## THE BOSTON MEDICAL AND SURGICAL JOURNAL.

March 5, 1908.

1. The Surgical Treatment of Various Conditions as Influenced by Pregnancy, By MALCOLM STORER.
2. A Case of Acute Dilatation of the Stomach and Duodenum (in a Moribund Phthisical Patient) Simulating a Terminal General Peritonitis, By THOMAS ORDWAY.
3. The Boston Medical Library. Its Past, Present and Future, By JAMES F. BALLARD.

1. **The Surgical Treatment of Various Conditions as Influenced by Pregnancy.**—Storer considers the view, held universally until comparatively recently, and still having much weight in the minds of most general practitioners, that pregnancy is a condition of *noli me tangere*, in which operations of all kinds are to be avoided, chiefly from fear of interrupting pregnancy. That the organism then has quite enough to do without being subjected to the additional strain of a surgical operation, of whatsoever nature, that can just as well be deferred is selfevident. From a critical survey of much of the wealth of material bearing on this subject, some 700 papers, it is evident that nearly all operations have practically no influence upon the course of pregnancy, except to favor its continuance, provided that they are not followed by a septic process which, by reason of continued high temperature, may cause the death of the fœtus and abortion. A glance at the following list of reported operations, by which pregnancy was not interrupted, will make this evident: External genital: Incision of hæmatoma, extirpation of hypertrophied clitoris and labia, extirpation of Bartholin's glands, extirpation of labial abscess, sarcoma of labia and vagina, perineorrhaphy, prolapse operation, periurethral sarcoma, fistula in ano, hæmorrhoids. Vagina and cervix: Excision of cicatricial stenosis vagina, curettage of cancer of cervix, scarification of cervix, cauterization of cervix. Uterus: For incarcerated retroflexed uterus, adhesions, curettage of uterus septus (at three months). Miscellaneous: Curettage of bladder, exploratory laparotomies, fibrosarcoma of abdominal parietes, nephrotomy for pus, nephrotomy for stone, nephrectomy, nephorrhaphy, other kidney operations, extirpation of spleen, cholecystotomy, resection of pylorus, resection of sigmoid, Cornell thyroidectomy, amputation of breast, inguinal and umbilical hernia, general peritonitis, tuberculous peritonitis, dermoid of mesentery, hydrosalpinx. In the next group of reported cases abortion has followed more or less closely upon operation: Labial polyp, carcinoma of vulva in which bladder was injured, cervical polyp, amputation of cervix, vesicovaginal fistula, removal of stones from bladder, tumors of pelvis, cancer of rectum, echinococcus cyst, ileus, crural hernia, pyosalpinx, cysts of vagina removed, appendicitis, ovariectomies, myomectomies. In many of these cases in which abortion followed it was at so appreciable an interval that it may be questioned with propriety whether it was caused by the operation; in fact, some writers hold that in no case is the operation the direct cause of miscarriage, but merely determines a miscarriage that is bound to come any-

way. An examination, then, of the foregoing list will show that operations of the most varied nature can be performed with very little danger of interrupting pregnancy, with two exceptions: In 9 operations for vesicovaginal fistula abortion followed in four, and in 25 operations for crural hernia it took place six times.

## THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

March 7, 1908.

1. Symptomatology and Diagnosis of Acute Articular Rheumatism, By PHILIP KING BROWN.
2. Cardiac Complications of Acute Rheumatism, By ALEXANDER LAMBERT.
3. The Vaccine Treatment of Gonorrhœal Vulvovaginitis in Children, By WILLIAM BUTLER and J. P. LONG.
4. The Common Ground of Medicine and Dentistry, By F. L. FOSSUM.
5. Subphrenic Abscess as a Complication of Appendicitis, By DANIEL N. EISENDRATH.
6. The X Ray and High Frequency Treatment of Exophthalmic Goitre, By FINLEY R. COOK.
7. Local Arteriosclerosis, By F. FREMONT-SMITH.
8. Perinephritic Abscess Following Parturition, By J. SHELTON HORSLEY.

1. **Symptomatology and Diagnosis of Acute Articular Rheumatism.**—Brown summarizes his article thus: Diseases with acute joint symptoms which resemble each other in the character of the joint involvement and in the accompanying complications belong to a definitely infectious group. The nature of the infection is clear in the following group: Group 1.—Septicæmia, pyæmia, puerperal fever, typhoid, pneumonia, epidemic meningitis, influenza, dysentery, gonorrhœa. The character of the disorder is established as definitely infectious in: Group 2.—Scarlet fever, smallpox, dengue. An infectious origin is presumed on good analogical evidence in: Group 3.—Acute articular rheumatism, acute arthritis deformans, Still's type, and the erythema group. When the infectious diseases with acute joint symptoms and known ætiology and also those infectious diseases with established identities but still doubtful ætiology have been taken out, there remains another group which contains acute articular rheumatism, acute arthritis deformans, and the erythema type of lesions. That specific toxic agents are responsible for these conditions seems a matter of no doubt, and that these agents differ from each other seems likely. The final diagnosis of acute articular rheumatism can be made only when Groups 1 and 2 have been excluded and when there are clinical distinctions clearly separating the diseases in question from the other members of Group 3. There are cases in all groups which can be diagnosed only by the lapse of time, and some which cannot at present be differentiated at all.

2. **Cardiac Complications of Acute Rheumatism.**—Lambert observes that it can not be reiterated too often or emphasized too strongly that the cardiac affections of rheumatism occur in all their intensity without any ratio to the extent of the joint manifestations, and the intensity of the cardiac involvement in both children and adults is not necessarily in any ratio to the intensity of the other symptoms. Many of the symptoms which we have heretofore believed due to endocarditis occur with the myocarditis and must be considered as equally due to this condition. After the acute joint symptoms have subsided, it is often noticeable that the

March 14, 1908.]

patient's temperature does not come down to normal and remain there; there is a continued run of temperature from subnormal to subfebrile, from  $97^{\circ}$  or  $98^{\circ}$  to about  $100^{\circ}$ , and it may rise as high as  $101^{\circ}$ . This invariably means an actively continuing endocardial or myocardial inflammation. The pulse may range near normal or be slightly above. In the subacute forms, in which the degeneration of the muscle is more common than in the acute inflammatory condition, and in the chronic condition, the pulse rate may be distinctly below normal. Heart disease, in the early half of life, is mainly of rheumatic origin, and we have come, in late years, to realize that the treatment of heart disease has more and more become the treatment of the cardiac muscle. We have now reached the position where we must realize that our knowledge of rheumatic endocarditis is still fragmentary and very incomplete. Heretofore our knowledge has been chiefly focused on the endocardial and pericardial involvement to the exclusion of the myocardial, but to-day we realize that the cardiac involvement of rheumatism includes endocarditis, pericarditis, and myocarditis, and the most serious is myocarditis.

**3. The Vaccine Treatment in Gonorrhoeal Vulvovaginitis in Children.**—Butler and Long report twelve cases treated with vaccination of gonococcus serum and twelve cases treated locally. They came to the conclusion that vaccine therapy has a place in the treatment of gonorrhoea in the female, that it appears to be far more efficient and at the same time scientifically more tenable than local antiseptic treatment.

**4. The Common Ground of Medicine and Dentistry.**—Fossum, in speaking of the common ground of medicine and dentistry expresses his opinion as follows: The dentist must appreciate the fact that the mouth is a part of the whole body, an important part, but only a part. He must think in terms of interchangeable scientific expressions of thought, so that his findings, observations, and deductions are easily interpreted by the physician. He must keep pace with the best in medicine, for only those physicians who stand for what is best in medicine can and will appreciate what is best in dentistry. The mediocre man in either profession will of necessity stick to his own particular line, but if the dentist will record and read his daily findings correctly he will find that his experience must more and more elucidate some of these problems of medicine, his work will be of double interest to himself, and he will open up fields hitherto undreamed of. The physician, on his part, must recognize that the mouth as a seat of disease is often overlooked, and that the logical consultant in many cases is the dentist, who, by virtue of his constant clinical experience of the normal in the mouth and teeth, must acquire the knowledge that is necessary for the unraveling of symptoms pointing to the mouth as a seat of trouble. Let the physician choose his consulting dentist with the same care that he does his consulting surgeon, for all his patients will have to visit a dentist, while only a small proportion will need surgical intervention. Let him keep abreast to a small extent of dental literature, not necessarily the most technical but the general literature. Let the dentist think and

work in terms scientifically interchangeable with the physician; then, and then only, will the common ground need no defining.

**5. Subphrenic Abscess as a Complication of Appendicitis.**—Eisendrath says that there are five methods of draining a subphrenic abscess: (a) By an incision in the epigastrium; (b) by an incision along the costal arch; (c) by an incision in the lumbar region; (d) by the transpleural route; (e) by pushing the pleural reflection upward and opening the abscess cavity through an incision in the diaphragm without opening the pleural cavity. The first three methods are indicated when there is bulging in the epigastrium along the costal arch or in the lumbar region. A simple incision will suffice to evacuate the abscess. If, however, suppuration continues and septic symptoms reappear, it indicates either an accompanying empyema or insufficient drainage, or, finally, a persistence of the original focus. Such conditions require more extensive operations. The ideal method of opening a subphrenic abscess, no matter what its origin may be, is by one of the last two methods, viz., resection of ribs over the area of suppuration with or without opening of the pleural cavity. If it is necessary to open the pleural cavity several methods can be employed. If possible, the diaphragmatic pleura should be sutured to the costal pleura. If there is much bulging of the diaphragm it is best to aspirate some of the pus lying beneath it before suturing. If it is impossible to bring the diaphragm to the chest wall the general pleural cavity can either be walled off with gauze or a larger portion of the ninth and tenth ribs can be resected.

**7. Local Arteriosclerosis.**—Fremont-Smith remarks that arteriosclerosis is frequently in its inception, a local disease dependent on acute or chronic infections. Its final lesion is controlled by the extent of primary vessel injury and the success or failure of natural reparative processes. Arterial hypertension exists in some instances independently of arteriosclerosis, and may or may not produce or be associated with causes which produce cardiac vascular phenomena. Arteriosclerosis exists independently of arterial hypertension as both a general and a local disease, and the absence of hypertension must not be regarded as security from dangers arising from arterial degeneration.

#### MEDICAL RECORD.

March 7, 1908.

1. The Opportunities of a Great Medical Society.  
By THOMAS F. SAUTHERSWAITE.
2. Report of Three Years' Work at the Sea Breeze Hospital for the Treatment of Surgical Tuberculosis in Children.  
By LEONARD W. FLY and BRANFORD H. WHITEBICK.
3. Some New Facts Regarding Heart Disease.  
By W. WACHENFELD.
4. "The Flowers that Bloom in the Spring." With Variations and Digressions.  
By W. B. KANSIE.
5. A Plea for the Correction of Uterine Displacements.  
By FRANK H. HANCOCK.

**3. Some New Facts Regarding Heart Disease.**—Wachenfeld says that it has been stated that the general tone of a normal heart can be increased through a course of gymnastics, and that this would improve the strength of the contractile

elements of that organ. This applies also to the body muscles, and against it the following may be said: Every human being is endowed at birth with a maximum ability to develop his musculature. The muscles, including the heart, can develop only to the extreme limit of this ability. The condition necessary to a healthy maximum muscular development is normal metabolism; this simply means the conveyance of normal nutrient substances to the muscle cell, and normal removal of waste. This is important, as not a single cell in the entire body receives its nourishment other than through the lymph channels. The lymphatic clefts reach directly every cell of all the organs in the economy. The capillaries, however, reach only to the clefts. We must, for this reason, and for many others which do not come within the scope of this work, regard the lymphatics as the carriers of cell nourishment. The force which propels the lymph within the closed system of channels is mainly derived from muscular energy. For these reasons active muscular work, or passive, massage, is necessary to healthy metabolism. Absorption of the nutrient moving material within the lymphatics can take place properly only when muscular relaxation and contraction normally alternate. Excessive muscular exertion causes congestion of lymph. The author has in mind, in making this statement, the lymph stagnation often seen in the muscles of the legs after long marches, and the same condition in the arm after protracted fencing bouts. The heart performs always as much work as the nutrition of its cells will allow. Overstraining of the heart—and each muscular act intensifies and accelerates its work—must lead not only in the normal, but particularly in the diseased organ, to congestion of its lymph channels. We can, however, stimulate metabolism of the diseased heart if we increase to a maximum the period of rest between the contractions and retard its action. For these reasons digitalis, rest in bed, and thermal baths act invigoratingly upon the diseased heart, whereas it is always, and in any case, harmed or damaged by gymnastics.

5. **A Plea for the Correction of Uterine Displacements.**—Hancock remarks that statistics show that the fecundity of the American woman is below that of any other woman of the world, the average number of children being as low as 2.5 per marriage. Discounting the large number that insist upon defeating nature's great purpose, there are still a multitude seeking relief from sterility. Flexions do not cause sterility by mechanical obstruction, as formerly supposed. Spermatozoa will pass any point that will permit the exit of menstrual blood, but the attending endometritis is a factor. Sims found fifty per cent. of his cases of sterility were associated with dysmenorrhœa, or really endometritis. In cases not due to infection endometritis results from interference with the circulation, with its attendant phenomena, proliferation of the glandular structures, and leucorrhœa. The epithelium that develops is of poor quality and embryonic in character, on account of venous congestion occurring in place of the arterial blood that supplies the normal endometrium, giving a shaggy, thickened, mushy surface, which the villi of the impregnated ovum cannot readily penetrate, as they must do if the ovum is firmly

planted and properly nourished. Again, the excessive secretion pouring from the utricular glands is apt to wash away the ovule, just as it often sweeps out of the uterus the spermatozoa ascending to the distal end of the tube. Nature arranged that the spermatozoa should be deposited in the vaginal vault and that the cervix should be immersed in this spermatic fluid, and any alteration of this arrangement is at least, as Bissell observes, "discouraging to fecundation" and should be corrected.

1. Some Abdominal Tumors Simulating Malignant Disease, and Their Treatment, By A. W. M. ROBSON.
2. Surgical Aspects of Subphrenic Abscess, By H. L. BARNARD.
3. Observations on the Incidence and Spread of Cancer, By G. L. CHEATLE.
4. A Form of Oral Filter to Be Worn During Operations by all Persons Inside the Operating Room, By G. E. DUNCAN.
5. Appendicitis at Sea: With Remarks on the Surgical Equipment of the Mercantile Marine, By A. E. JOHNSON.

1. **Pseudomalignant Abdominal Tumors.**—Robson, from a considerable experience of abdominal tumors that have simulated malignant growths, but which, arguing from the sequel of events and the ultimate complete recovery of the patient, must probably have been inflammatory, concludes that such tumors are much more common than is generally supposed. Guarded prognoses should more frequently be given in the case of abdominal tumors having the appearance and feel of cancer, and even having the clinical signs and symptoms. The writer cites a number of instances of inflammatory tumors of the colon in which resolution occurred. The pathology of the cases was probably a chronic infiltrating colitis, possibly associated with pouches lodging fecal matter, or may be simply due to infection spreading through the intestinal walls. Two forms are commonly described, chronic adhesive colitis, in which the onset is usually acute, and chronic infiltrating colitis or proctitis, in which the onset is insidious and the progress slow. Both are associated with progressive constipation and with great loss of flesh and strength. The fact that cancer is complicated with inflammation makes a positive diagnosis extremely difficult and at times impossible, but fortunately the treatment of securing physiological rest by operation is curative if the disease fortunately turns out to be a primary inflammation and not secondary to growth. Chronic tuberculous disease of the cæcum may closely simulate cancer. The liver is not infrequently the site of simple tumors suspected to be malignant, and if they are associated with rapid loss of flesh and more or less jaundice, the diagnosis of cancer is very apt to be made. The writer reports a number of cases of simple abdominal tumor simulating malignancy, all going to support the proposition that, if the diagnosis is doubtful and the patient is at all in a condition to bear operation, exploratory laparotomy should be performed. Not only may a removable cause of the jaundice be discovered, but it may fortunately happen that, even if the diseases appear to be incurable on exposure, the operation *per se* may have some hitherto unexplained influence leading to recovery.

Such exploratory operations, if undertaken with proper care and skill, are almost devoid of danger, so that, even if no real good can be done, no serious harm can follow.

**2. Subphrenic Abscess.**—Barnard has analyzed seventy-six cases of subphrenic abscess, and among his findings are the following: About one third the cases were due to perforating gastric and duodenal ulcers. In the majority of the cases due to gastric ulcer the perforation was on the anterior wall of the stomach and near the lesser curve. The septic matter escaped direct into the left anterior intraperitoneal space and the abscess was localized there. About one sixth of the cases were due to appendicitis, which may infect the subphrenic fossæ in four ways: 1. As a part of an acute general peritonitis. 2. By a more or less slow and direct extension up the lumbar peritoneal fossæ, from the pelvis. 3. Through the medium of the portal vein, as a part of pyelophlebitis. 4. By lymphatic extension (a) up the right retroperitoneal cellular tissue, or (b) up the lymphatics around the deep epigastric artery to the falciform ligament. Another one sixth of the cases was due to hydatid and tropical abscesses of the liver. As a liver abscess enlarges it tends to thin out the liver substance over it and comes to the surface. In the majority of cases the right anterior intraperitoneal space is infected, the layers of the coronary ligament being pushed aside until the diaphragm forms a considerable part of the upper boundary of the abscess. The diagnosis of a subphrenic abscess is not really difficult if the examination is conducted in an orderly and complete manner, as follows: 1. (a) History. In many of the cases due to gastric ulcer there is a characteristic history of dyspepsia and hæmatemesis, in those due to appendicitis of previous attacks, and in the case of tropical abscess of the liver of foreign residence and of having suffered from dysentery, malaria, or typhoid fever. The duration varies from one day to sixteen months, but averages eight weeks. (b) Onset. The great majority of intraperitoneal subphrenic abscesses begin with an acute perforation into the peritonæum, whilst extraperitoneal collections of pus below the diaphragm result from a spreading cellulitis and are therefore slower in their beginnings. Pain is nearly always the first symptom of the onset of a subphrenic abscess, and is referred in every case to the situation where the abscess forms. In perforative cases it is sudden, severe, and stabbing. Vomiting is the next symptom in point of frequency and time, and is almost restricted to those subphrenic abscesses which originate in a perforative peritonitis, and especially to gastric and duodenal cases. Nausea, hiccup, collapse are occasionally observed at the onset, which may also be preceded by a period of obstinate constipation. When the abscess becomes well localized septic diarrhoea nearly always appears. Hæmatemesis and melæria are usually due to hæmorrhage from a gastric or duodenal ulcer, but occasionally they arise from a chronic and insidious subphrenic abscess which has ruptured into the stomach and has then become acute in its progress. 2. General signs and symptoms. In nearly all cases an examination of the general symptoms points to the presence of a collection of pus below

the diaphragm. The tongue is dirty and dry, the face pale and muddy. In most cases there is profuse sweating, with weakness, dyspnoea, and no appetite. Wasting is a very constant sign, and there is usually a profuse septic diarrhoea. Fever is always present, but may be slight in amount. Chills occur in about one seventh of the cases, and are a very fatal sign. Leucocytosis is present in all cases, the polymorphonuclear leucocytes being greatly increased. In two out of three cases due to hydatids of the liver, eosinophilia was noted. 3. Abdominal signs and symptoms. An abdominal swelling is present in the great majority of the cases. This swelling does not descend on respiration, because it is adherent. The part formed by adhesions is rigid, tender, and dull on percussion; that formed by pus in contact with the abdominal wall is scarcely tender, bulges and fluctuates, and is dull on percussion. Where gas is present a tympanic area is formed, high up in the epigastrium as a rule, and over the liver dullness, amphoric and coin sounds can be obtained, and the tympanic area travels around the chest as the patient is rolled over. In only a very few of the cases is the liver dullness lost. 4. Thoracic signs and symptoms. These are present in most cases, the conditions indicated being those of compression, and inflammation of the base of the lung and pleura, namely: (a) Displacement of the lung upwards and obliteration of the lower pleural angle. (b) Dry pleurisy. (c) Pleural effusion. (d) Compression of the lung. (e) Consolidation of the lung. (f) More or less bronchitis at the base. The most frequent association of signs is dullness, with diminution or absence of breath sounds, vocal resonance, and tactile vocal fremitus. 5. Local signs. These are found over the abscess and encroaching upon the thorax or abdomen or both. In many cases the abscess causes a visible bulging of the thorax or a definite swelling in the abdomen. The circumference of the thorax may be greater on the side of the abscess, and deep tenderness is sometimes present. In the only case in which the x rays were used, the abscess showed as a deep shadow. The proper use of a good aspirating needle on the operating table and under a full anæsthetic is the most certain means of diagnosis we possess. The only safe rule in thoracic operations is to follow the needle; it is useless to make a large opening and admit air to the pleura unless pus is present. Needling should never be abandoned until it is certain that no pus is present, but a promiscuous search for pus with an ineffective syringe is dangerous and deceptive. Of the seventy-six cases investigated forty patients lived and thirty-six died, a case fatality of 47.4 per cent. Twelve patients were not operated upon and all died, a fatality of 100 per cent. Of the sixty-four operative cases, 24 patients died, a fatality of 37.5 per cent. Posterior operations gave the best results. Half the avoidable deaths could be attributed to the fact that the condition was not diagnosed, the other half to the absence of exact and detailed knowledge of the localization and character of subphrenic abscesses on the part of the surgeons. With a perfect opportunity, knowledge, and technique the seventy-six cases might have been treated with an ideal fatality of no more than 10 per cent.

Calculus, By C. J. MORTON.
7. "Dammed Circulation" and "Interrupted Circulation."  
A Note in Nomenclature, By W. EWART.

## 2. Gastric Function and Gastroenterostomy.

—Gray sums up his conclusions as follows: 1. The cardiac and pyloric portions of the stomach are distinct in development, structure, function, and pathology. 2. During the early stage of gastric digestion the pyloric portion is normally empty and tonically contracted. When food has attained a proper chemical reaction in the cardiac enlargement it passes into the pyloric portion. 3. Bearing this in mind, care should be taken in performing gastroenterostomy to make the opening in the stomach wall within the pyloric portion as near the pylorus as possible. This will then, if the stomach has not irremediably lost its muscular power, provide against an "uncontrolled escape of the acid gastric contents," which is asserted to occur in cases of gastroenterostomy. If pyloric spasm is present the stomach will act as a safety valve and remove the spasm. If pyloric stenosis exists the natural condition of things will be most nearly approached and the "regulating action" of the pylorus, so necessary to perfect digestion, be most nearly approximated.

3. Night Blindness.—Parsons states that complaint of inability to see in the dusk or foggy weather at once suggests the disease commonly known as retinitis pigmentosa. In this disease there is comparatively little disturbance of central vision. Examination of the fundus shows in the early stages in young patients a zone of characteristic retinal pigmentation in the neighborhood of the equator; both peripheral or central to this zone the retina looks almost or quite normal. The pigmentation shows characteristic spots shaped like bone corpuscles, and aggregations along the perivascular sheaths of the retinal vessels. The progress is usually slow, and central vision is seldom lost by direct extension of the disease, as before this happens a posterior cortical opacity usually appears in the lens. Another chronic form of night blindness is met with which differs from retinitis pigmentosa in that it is stationary. This form is always hereditary, and shows no gross changes in the fundus. Syphilitic pigmentary retinitis constitutes a group of cases intermediate between idiopathic retinitis pigmentosa and congenital night blindness. Malnutrition occasionally causes night blindness, it having been observed in alcoholism, scurvy, malaria, and nephritis, most of the patients having reflex blepharospasm (photophobia) in bright sunlight. Another group of cases are those

associated with jaundice; it may be noted that bile salts are a solvent of the visual purple.

6. X Ray Diagnosis of Urinary Calculi.—Morton, in order to diagnosticate urinary calculi by means of the x rays, tests the efficacy, quantity, and penetrating quality of the rays, uses a set of calculi of known composition and size as a means of testing the actual effects of the rays while they are passing through the patient. If the rays are of sufficient strength, shadows of the individual calculi will appear on the fluorescent screen, and can be readily recognized. If no shadows can be seen it means the rays are inadequate.

7. "Stauungshyperämia."—Ewart suggests that the term "dammed circulation," introduced by Thomas thirty years ago, be used to express in English the German *Stauungshyperämie*—the condition produced by Bier's method of treatment. "Passive congestion," "passive hyperæmia," and "stasis hyperæmia" are all unsatisfactory. "Dammed circulation" is even more strictly inclusive than the German term, for it implies the manœuvre and covers the entire field of its operations. arteries, veins, capillaries, plasma, and lymphatics.

## LA PRESSE MEDICALE

1. The Lower Segment of the Uterus. General Idea of  
Its Anatomy, Physiology, and Pathology,  
By CYRILLE JEANNIN.
2. Do the X Rays Produce Cancer? By G. HARET.
3. Palpation of the Normal Stomach, By G. FISCHER.
4. Artificial Parabiosis in Cold Blooded Animals,  
By R. ROMME.

1. The Lower Segment of the Uterus.—Jeannin studies the lower segment of the uterus during pregnancy, during labor, and during involution. The term lower segment is obstetrical rather than anatomical or surgical; the puerperal uterus is divided into three zones, the body, the lower segment, and the neck, and these correspond in the nonpregnant uterus to the body, the isthmus, and the neck, hence the lower segment or intermediate portion corresponds to the isthmus. The anatomical study is followed by a brief glance at the physiology and pathology of the lower segment.

15. Medical Support of Quackery, By KLEIN. By KANTOR.

**1. Experimental Diagnosis of Tuberculous Disease.**—Weber considers that the finest and most positive demonstration of tuberculosis is the experiment in which supposedly tuberculous material is injected beneath the skin of the abdomen of an animal. If the material is tuberculous the lymphatic glands in the neighborhood of the injection can be felt at the end of from ten to sixteen days, and if these glands are removed the presence of tubercle bacilli within them can be easily demonstrated. This experiment is of special value in distinguishing bacilli found in the urine, smegma, and tubercle, as these resemble each other in their staining and morphological properties.

**2. Frequency of Tuberculosis and the Two Principal Times of Infection in Infancy.**—Sehlbach comes to the following conclusions: 1, The frequency of tuberculosis in infancy does not increase from month to month; as has been assumed heretofore, but a retrogression takes place toward the ends of the first and of the second years. 2, Correspondingly there are two principal points of time of infection, (a) in the first three months of life, crade infection; (b) creeping, or dirt, or smear infection about the turn of the first year; the possibility of an infection at any other time cannot be excluded. 3, In general, artificially fed children fall victims to tuberculosis most quickly, those partially breast fed next, and those nursed wholly at the breast latest. 4, This shows the great protective power of the mother's milk against tuberculosis.

**4. Influenza Bacilli in the Bronchi.**—Wohlwill, on account of the pandemic of influenza, instituted a bacteriological examination of the smallest bronchi in 158 cadavers. Seventy-five of these had suffered from phthisis, twenty-six from acute infectious diseases, and fifty-nine from various other diseases. The bacteriological examination revealed the *Streptococcus pyogenes* sixty-eight times; the *Staphylococcus pyogenes aureus* thirty times; *albus* six times; the *Diplococcus lanceolatus* forty-six times; the *Bacillus pneumoniae Friedländer* seven times; the *Bacillus coli communis*, the *Bacillus pyocyaneus*, the *Bacillus diphtheria*, each twice; the *Bacillus influenzae* twenty-nine times; influenza like rods five times; and three kinds of not identified germs. In ten cases no microorganisms were found. Further analysis showed that the influenza bacillus was present in 22 per cent. of the cases of pulmonary tuberculosis, in both of the patients that had died of measles, and in the six patients that had died of whooping cough, but in only one of the adults that had died from various other diseases.

**6. Arthrodesis.**—Vulpus deals with the indications for this operation in the various joints, and then pictures some remarkably good results which he has been enabled to obtain in this manner.

**8. Vaginal Cesarean Section on Account of a Rare Indication.**—Voigt reports a case in which he performed this operation because of a severe bronchial asthma with secondary cardiac insufficiency and pulmonary edema, aggravated by the

physiological compression due to the nine months' pregnant uterus, which imminently threatened the life of the mother.

**9. A Case of Cholesteatoma.**—Beyer reports a case of cholesteatoma which varied from the usual in several of its characteristics. The patient was a soldier under observation, who was seized with an acute suppurative inflammation of the middle ear, on account of which paracentesis was performed, and later, as the suppuration proved not amenable to treatment, a radical mastoid operation. This final operation revealed the cholesteatoma, which may therefore be said to have run a symptomless course.

#### THE MILITARY SURGEON.

March, 1908.

1. Plague in India. By ARTHUR HENRY MOORHEAD.
2. Benjamin Rush's Directions for Preserving the Health of Soldiers, with a Note upon Surgeon Ebenezer Alden. By HENRY PELOUZE DE FOREST.
3. Notes and Statistics of the Year's Service at the United States Marine Hospital, San Francisco, Cal., By H. W. AUSTIN.
4. Instruction in the Physiology of the Circulation. By ROBERT S. WOODSON.
5. In Memoriam: The Necrology of the Association for 1907. By SAMUEL C. STANTON.
6. Heat Exhaustion on Men-of-War. By MIDDLETON STUART ELLIOTT.

**1. Plague in India.**—Moorhead remarks that the future outlook and likelihood of the spread of the plague to Europe and America is a very serious problem. The disease in eleven years has spread through the whole of India, and will no doubt next infect Afghanistan and Persia. These countries lie in the northwest frontier and are adjacent to Russia in Europe, and they are not likely to adopt more vigorous measures than have been done in India. Wherever the plague carrying rat and its flea, the *Pulex Cheopis*, can travel and live the disease is sure to spread to, and it will reach Europe overland. He describes his method of treatment as follows: All plague patients were removed to plague hospital on the boundary of cantonment. This hospital consisted of several grass built huts with open doors and very free ventilation. The sick attendants, hospital assistants, and staff of servants lived in tents close by and were never changed. A guard over this hospital prevented all communication and permitted only the medical officer to enter it. All contact cases were isolated in a camp for ten days and daily inspected, and their clothing disinfected in perchloride of mercury lotion and placed in the sun for four hours. A medical inspection of the whole regiment and followers was made daily, and an airing of all kit, clothing and bedding in the sun for four hours daily. All the barracks occupied by the men and followers' huts were disinfected by swabbing floors and walls with strong perchloride of mercury or carbolic, and later were all lime washed. All huts in which cases of plague had occurred had the roofs removed and remained in this state for a couple of months. All dead rats found were burnt with kerosene oil and special disinfection of places in which they occurred. Inoculation was not carried out. Rat destruction was not employed, and the importance of the flea not then known. Buboes which mostly were in the groin were opened and dressed antiseptically. The present treatment is to

open and drain these at a very early date and prevent the poison entering the system. The strength of the patient was kept up by suitable diet, and stimulants were freely given. He also tried internally large doses of carbolic acid freely diluted. Doses as large as eight grains twice or thrice daily were given. The rest of the treatment was symptomatic. For the very high fever, ice to head, cold packings, and iced water enemata were employed, and stimulants freely given in the event of cardiac failure. The result, the author says, was very satisfactory, as the mortality was only 65 per cent. A curious after effect in many patients was an affection of speech and difficulty in articulating words.

### Proceedings of Societies.

#### MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

*Special Meeting, Held in the Borough of the Bronx,  
January 6, 1908.*

Dr. N. B. VAN ETEN in the Chair.

#### On Some Newer Aspects of Cardiac Pathology.

—The first paper of the evening was read by the president, Dr. THOMAS E. SATTERTHWAITE, on this subject. The first positive advance in cardiac pathology, he said, was made in 1826, when Laennec announced his discovery of fatty degeneration as a myocardial disease; but it was not until a quarter of a century later that the matter was turned to practical account. In Quain's classical monograph, published in 1850, Laennec's fatty degeneration was distinguished clinically from the fatty deposition of the fat heart, and five years later Stokes elaborated still further the topic of myocardial diseases, being the first to recognize the fatty hearts of infective disease, especially typhus and typhoid. Having referred to the discovery of the syphilitic heart by Ricord and the "irritable heart" by Da Costa, he stated that in 1876 Bristow showed that the interstitial cardiac tissue, as well as the muscle tissue, of the heart, might also be implicated, so as to cause a diffuse myocarditis. A further advance was made when Romberg, in 1891, traced myocardial disease to diphtheria and scarlet fever, while Huchard, in 1891, showed that the source of the interstitial inflammation might be the coronary vessels.

As a result of these pioneer discoveries and of still later investigations, we had now reached a point where it could be said with confidence that all toxæmias, whether acute or chronic, some dyscrasias and hyperpyrexias, if long continued or severe, and some other conditions which would be mentioned later, produced definite morbid changes in the heart walls, evanescent or permanent, as the case might be. To the profession at large these matters were comparatively new, since attention hitherto had been mainly directed to diseases of the endocardium and pericardium; yet the condition of the heart substance was always of paramount importance. As regarded the term myocarditis, however, we had to face the fact that its use had led to some misapprehension. It had been and was

still employed somewhat indiscriminately for various myocardial diseases, and to most physicians myocarditis implied an inflammatory process, and did not therefore include the degenerative affections of the heart. The speaker then offered a new classification of these diseases, as follows: 1. Acute parenchymatous myocarditis. 2. Acute diffuse myocarditis, including the tuberculous, syphilitic, and suppurative forms. 3. Chronic myocarditis, including all the diffuse inflammatory changes mentioned. 4. The fat heart. 5. The fatty heart. 6. Hypertrophies, whether due to severe exercise, vascular diseases, blood disorders, neurotic disturbances, or possibly pregnancy. Dilatation could not be called a disease, being an incident which might occur at times in any of the varieties enumerated.

Some such classification as that now given, he thought, was essential to a clear conception of myocardial diseases, though many of the pathological phenomena mentioned might be interconnected in any single instance. A parenchymatous myocarditis might be but the first indication of the diffuse form, even though the character of the parenchymatous change was not fully understood. It might, however, be presumed, from what we knew of similar processes elsewhere, that parenchymatous changes might produce not only necrosis of the muscle cells, but, in addition, fatty degeneration, leading to dilatation and possibly rupture of the heart. Harlow Brooks had recently published statistics showing that, of 457 cases of which he had personal post mortem records, where death was the result of cardiac lesions, 330 showed evidences of diseased heart walls, while in many others myocardial diseases figured as additional subsidiary factors. Yet these diseases, which were largely responsible for the fatal endings, were not recognized during life in a very considerable number of instances. Of these 457 cases, in 214 there was chronic endocarditis, in 51 acute endocarditis, and in 66 pericardial diseases; so that, throwing entirely out of account the myocardial affections which complicated endocardial and pericardial disease—which might of themselves have been the cause of death in many and possibly most instances—126 out of the 427, or about twenty-eight per cent, were believed to have been due to uncomplicated degenerative disease of the heart walls. From his own clinical records, Dr. Satterthwaite would say that in forty-five per cent. of his deaths in heart cases degenerative cardiac changes were the principal predisposing causes of death, though at the end in very many uræmic poisoning was an active controlling factor. The statistics gathered by Roemer in Liebermeister's clinic corresponded very closely with these figures. The later statistics of Romberg showed that chronic cardiac insufficiency (by which he meant chronic myocardial disease) was the most common heart affection, and if we added to the chronic forms the uncomplicated acute myocardial forms associated with infections, dyscrasias, anæmias, etc., it could readily be seen that myocardial diseases were very much more common than valvular diseases. Moreover, as other organic heart diseases were comparatively rare, and as myocardial disease was apt to complicate valvular

disease, it could well be asserted that myocardial diseases were more common than all other forms of heart diseases combined, in the sense that they entered as a factor.

The speaker then took up in detail a number of the forms of myocardial disease, as given in his classification, and some of the statements made were as follows: Parenchymatous alteration was the earliest form of muscle metamorphosis. Schmalz, whose experience was very large, had sometimes found acute myocarditis within a few days after the inception of an attack of diphtheria, and myocardial disease occurred in sixteen per cent. of his diphtheria cases. Diphtheria was now held to be the most frequent cause of chronic myocarditis. Acute myocarditis occurred also in rheumatism, tuberculosis, amygdalitis, measles, lobar pneumonia, erysipelas, epidemic influenza, gonorrhœa, and septic processes, and according to present opinion the pathological changes noted were due either to the toxins of the diseases named or to the continued high temperature. In alcoholism a similar condition had been noted, though in this instance the alcohol itself was probably the poison to which the myocarditis was due. We could not dissociate these parenchymatous changes clinically from those of that acute myocarditis which was a somewhat later event in the pathological chain. This, however, presented a different microscopical picture, and what we were pleased to call acute myocarditis was found, from the microscopical appearances, to consist of a diffuse inflammation in which the muscular tissue was only one of the several elements involved. Occasionally abscess resulted, usually causing death; but the acute form of myocarditis might pass over into the chronic form. When hypertrophy of the muscular tissue occurred, more or less dilatation was likely to follow. Clinically speaking, if the left margin of the heart did not extend beyond the nipple, it was not regarded as an alarming sign, but if an inch beyond that point, the prognosis was unfavorable. In mild cases the dilatation (as shown by the apex beat) would not reach to the nipple. If, now, in the course of or following typhoid, diphtheria, or any of the acute or chronic toxæmias referred to, the pulse became weak and irregular, no matter what its rapidity, attention should be directed to the probability of the occurrence of some myocardial affection. If there were præcordial distress or cyanosis, dyspnoea, and, in extreme cases, anginoid attacks, the diagnosis of acute dilatation could be made with a reasonable degree of probability; which would amount to certainty if it was found that the heart's dimensions had suddenly become enlarged. While the parenchymatous change might result in acute diffuse myocarditis, and possibly terminate in fatty degeneration, it was found that in most cases the condition disappeared with convalescence, and that, so far as could be determined by clinical tests, the patient, wholly recovered.

Among the prominent causes of cardiac hypertrophy were arteriosclerosis, congenitally small vessels, scurvy, Marfan's disease, and the neuritic heart of hysteria. During the first stage of hypertrophy there was a gradual increase in the several tissues of the heart walls, with increase of the size of the muscle cells and perhaps increase in the num-

ber of cells. This stage was completed when the hypertrophy had become sufficient to propel the blood column with the required amount of force, and the second stage was marked by a return of the action of the heart and pulse to their normal condition. This condition, so far as we knew, might continue indefinitely, but if the heart began to dilate further the affection then entered upon the third stage, a period of failing compensation, temporary or permanent. In many cases a further access of dilatation would mean cardiac failure, and, if no relief was given, sudden death. The heart of the athlete was more apt to suffer from excitement or sudden strain than the normal heart, so that he must always be put upon his guard against sudden dilatation.

The two terms, fat heart and fatty heart, implied some semblance in intimate structure, and while it was true that, pathologically speaking, they were closely allied, there was in uncomplicated cases little clinical resemblance between them as to natural history, diagnosis, prognosis, and treatment. In the fat heart there was a deposition of fat between the muscle fibres or bundles, while in the fatty heart there was a fatty degeneration of the muscle fibres themselves. The character of the conditions existing in cardiac syphilis was now pretty fully understood. The disease might affect any part of the heart, and also the pericardium. The gumma or some tertiary infiltration was most often found, and might occur as late as ten or twelve years after the primary lesion. Cardiac syphilis was also one of the manifestations of the hereditary form of the disease. The condition yielded promptly to treatment if recognized before destructive changes had taken place.

**Instruments of Precision in the Management of Diseases of the Heart.**—This paper (to be published) was read by Dr. LOUIS F. BISHOP.

**On the Diagnosis of Diseases of the Heart.**—This paper was read by Dr. WILLIAM H. PORTER (see page 486).

**On the Use of Drugs in Diseases of the Heart.**—Dr. REYNOLD WEBB WILCOX, to whom this topic had been assigned, said that the wave of therapeutic nihilism which had of late years affected the profession was happily now passing away. Substitution and failure to observe the requirements designated by the pharmacopœia were punishable by severe penalties, so that reliance could be placed on the qualities of the remedies at our disposal. The work of the heart was determined to a very large extent by the condition (1) of the vessels, (2) of the cardiac walls, and (3) of the valves, the last named being of less importance than the others. Having referred to the value of the hæmoglobinometer and the sphygmomanometer, he expressed the opinion that the question of the blood pressure was as yet only in its infancy.

We could regulate the rapidity and the force of the heart's action, and there were three groups of remedies at our command for accomplishing this. As long ago as in 1783 Withering had correctly laid down the indications for the use of digitalis in a rapid low tension pulse, with venous congestion. This drug was indicated, in general, when the cardiac action was weak and feeble, with low arterial tension, and contraindicated when the cardiac action

was strong and arterial tension high. Digitalis, however, had its defects, and the principal of these was the pronounced vasoconstriction which it produced. This had led to the study of strophanthus as a substitute for it in suitable cases. Strophanthus was found to be less of a vasoconstrictor and to have a more rapid action, and experience had shown that it should be used in place of digitalis in children and the aged. Dr. Wilcox had personally worked out its effects in the laboratory and in his clinics with the sphygmograph. Convallaria was untrustworthy, and adonidine, another drug of the digitalis group, which was now official, was objectionable on account of the renal irritation which it caused. Erythrophloeum, or sassy bark, the last of the five drugs of this group, was a remedy which slowed the pulse and raised the tension, just as digitalis did. He had made a careful study of its effects, and the results obtained in the laboratory were confirmed by clinical observations. As compared with digitalis, it was decidedly more active in slowing the pulse, but it was irritating to the stomach. As a vasoconstrictor it had a greater effect than digitalis; in fact, as great as digitalis and ergot combined. While it was less cumulative than digitalis, it was also rather less reliable. Its use, he thought, should be confined to those cases of fairly competent heart with low vascular tension, in which it would show its effects more markedly and rapidly, and to those cases in which digitalis had lost its usefulness or had entirely failed. In the most recent revision of the pharmacopœia the tincture of strophanthus and all potent tinctures had been placed at the uniform strength of ten per cent.

Then came the class of drugs which weakened the heart's action and slowed its rate, such as aconite and veratrum. Both these were of great value in appropriate cases. Veratrum was especially esteemed by the obstetricians, and the danger from its use had been much exaggerated, since it always gave ample warning when it was being carried too far. There was only one drug which both increased the force and frequency of the pulse, and that was cactus. It was especially useful in the neurotic heart and the slow heart. If an active preparation (and such was readily found in the shops) was used, in appropriate cases, brilliant results might be obtained. In pulmonary oedema with heart failure the speaker did not know of any remedy so good as hot coffee given by high rectal injection. By combining with each dose half a grain of caffeine sodiobenzoate, we could get along with much less digitalis than otherwise. Strychnine was sometimes of service in cardiac disease, but one difficulty with it was that patients readily became habituated to its use. As to cardiac syphilis, he had himself seen three cases of gumma of the heart wall, proved to be such in the dead house. In this disease he had found that arsenic iodide had sometimes proved efficient in cases in which the usual antisyphilitic remedies had entirely failed.

Dr. ROBERT E. COUGHLIN, of Brooklyn, said that he was interested in the subject of Dr. Satterthwaite's paper, because for a number of years he had given some time and thought to the subject as related to athletes and the strain put upon their hearts in athletic contests. As medical men we were not par-

ticularly interested in the professional athlete only so far as his life might become an example to the growing young, many of whom sought our advice when about to enter into athletics. The subject was very important when we considered that young schoolboys were at present put into contests by the public school instructors where their hearts were put to a very severe strain, as in sprinting and running a distance. There was great chance of injury being done to the heart by violent exercise in competitive games. His opinion was that the young exercised probably too much, and those over forty and fifty years not sufficiently. Take, for instance, he said, the case of the oarsman, Edward Hanlon, who died a few days ago. It was said that he was the most graceful oarsman who ever pulled an oar, and that he lost only six races out of 200. He also held the record for a four mile row. This man died at the age of fifty-two, after a two days' sickness, of pneumonia. It was known to be a fact that he took no exercise for ten years preceding his death. Was it not reasonable to suppose that, after an interval of inactivity, no exercise being taken for this period, myocardial disease was really the cause of his succumbing to pneumonia, in which the heart was markedly taxed? Twenty years ago Richardson, of London, pointed out a white spot on the heart, or myocarditis, in connection with the deaths of athletes. It was interesting to note that the reader of the paper described very well the pathology of this condition. Persons over forty ought to try to keep up their cardiac muscle, so that no degeneration should take place. Especially was this so in men who had overdeveloped their cardiac muscle. Take the instance of Weston, who at the age of sixty-nine walked from Portland, Maine, to Chicago, a remarkable feat for a much younger man to perform. Weston had kept up his cardiac muscle development uninterruptedly, as in an interview he professed to have taken regular exercise every day of his life. The great thing was to maintain our cardiac muscle and not allow degenerative changes to take place. A young man could map out his life's work in this respect, and it was our duty to explain to him what he should do to keep up his cardiac muscle once he entered into the athletic life.

Dr. EDWARD E. CORNWALL, of Brooklyn, thought the water sphygmomanometer of Dr. Bishop very ingenious, but unlikely to be of much practical use on account of the height of ceiling required, to say nothing of the step ladder. The sphygmomanometer which he preferred for general use was the Kaplan. This he found convenient and portable, though it frequently spilled out mercury, which, however, could be easily replaced if one carried a small bottle of mercury with him and a medicine dropper. As for the therapeutic nihilists to whom Dr. Wilcox referred, he was inclined to doubt if they existed to any important extent among regular physicians. He was inclined to believe that therapeutic nihilism was a bugaboo invented by those who were in the habit of using drugs excessively and without clear indications. These, who he thought constituted a very numerous class, he suspected of stigmatizing the advocates of conservative and rational therapeutics as therapeutic nihilists in order to distract attention and criticism

from their own prejudiced therapeutics. He was much pleased with Dr. Wilcox's remarks on strophanthus, and remembered reading in Wilcox and White's *Materia Medica* Dr. Wilcox's account of the action of that drug, which was the best description of it he had ever seen. He had used that drug extensively, and had learned to value it at least equally with digitalis. He thought its range in cardiac therapeutics was greater than that of digitalis, and, though not exactly coextensive, its action included much of the range of digitalis. He had found by clinical experience that for restoring lost compensation in valvular diseases in children it was better than digitalis, and in conditions of high blood pressure and in dilated hearts with greatly weakened myocardium he thought there was no question of its superior value. He thought that failure to get good results from its use were often due to the fact that it was given in too large doses, and that the doses advised in the textbooks were too large. He had also observed clinically that, while it was generally much less irritating to the stomach than digitalis, there were a few people who seemed to have an idiosyncrasy in regard to it, who got less therapeutic benefit from its use and more irritation of the stomach than they did from digitalis. A preparation of digitalis which he had found useful in bad cases and for which he wished to say a good word was the soluble digitoxin recently put on the market. In regard to cactus, of which Dr. Wilcox spoke favorably in spite of the investigations on the action of this drug and adverse conclusions recently reported in the *Journal of the American Medical Association*, he felt that he could say little, not having had sufficiently extensive experience with it. He was inclined to believe, however, that it was a cardiac sedative of value in functional disorders of the heart. Convulsaria he had found so vastly inferior to digitalis and strophanthus that he seldom used it. He was pleased that Dr. Wilcox omitted to make mention of sparteine, if, indeed, his silence was not meant for assent, for he thought we could well afford to ignore sparteine as a heart stimulant when we had so many better ones.

Dr. SATTERTHWAITTE said he would like to ask Dr. Wilcox's opinion of the value of adrenalin in cardiac failure.

Dr. WILCOX said that Dr. W. H. Bates was the first to demonstrate the effect of suprarenal extract on the eye and the larynx. He himself had been the first to make sphygmographic tracings under the use of suprarenal extract, and these corresponded very closely with those obtained with adrenalin later. Adrenalin should be employed for shock, he thought, only when this was due to dilatation of the bloodvessels of the splanchnic area. Unless it was used with great caution, a weakly acting heart might be overwhelmed.

Dr. SATTERTHWAITTE said he had heard of cases in which death was caused by adrenalin. Under its use the pulse ran up very high at first, but soon sank below normal, and he therefore regarded it as a very dangerous remedy. On the other hand, he had found the ordinary suprarenal extract distinctly useful at times, and was accustomed to employ it in his practice in appropriate cases.

Dr. WILLIAM H. PORTER thought there could be no doubt that the heart muscle underwent fibrous degeneration after an individual accustomed to taking active exercise stopped this. In affections of the heart, as in other diseases, the object of drugs in all cases was, not to cure the disease, but to enable Nature to continue the functions which had been interrupted. We should first seek the cause of the trouble, and then direct our remedies toward the removal or modifying of existing conditions. As regarded drugs, in many cases of cardiac disease he had come to place special reliance upon benzoic acid and caffeine.

#### WESTERN SURGICAL AND GYNÆCOLOGICAL ASSOCIATION.

*Seventeenth Annual Meeting Held in St. Louis, December 30 and 31, 1907.*

The President, DR. CHARLES W. OVIATT, of Oshkosh, Wis., in the Chair.

(Continued from page 475.)

**The Association or Confounding of Appendicitis with Other Diseases in the Female Pelvis.**—Dr. A. E. BENJAMIN, of Minneapolis, said that any inflammatory disease within the abdomen primarily involving one organ might from continuity or contiguity result in other tissues or organs being involved. The blood supply of the abdomen and pelvis was such that infectious microorganisms might be carried from one diseased organ to another, thereby starting a similar disease in a part through which this infected blood flowed. The lymphatics might also convey disease to organs in the line of their distribution. The nerve supply of the organs of the lower abdomen and pelvis and their sympathetic relationship were such that pain might be referred to localities not affected. It was possible for more than one form of disease to exist within an abdomen simultaneously, and the symptoms to become quite complex in consequence. Besides actual disease, there might exist a misplaced position of one or more organs, thereby changing the symptoms considerably, or resulting in contiguous organs being affected because of this displacement. Also the misplaced position alone might cause distress which resembled some actual form of disease. The character of the disease, the variety of each form of disease, the number of organs involved, the associated displacement of organs, the temperament, environment, and vocation of the individual were all factors to be considered in summing up the case. A careful personal history, a thorough physical examination of the individual, with the aid of chemical and bacteriological investigation, and a searching examination with all the apparatus at command, i. e., the cystoscope, proctoscope, microscope, and x ray, would clear up the majority of cases. In certain cases, if no positive diagnosis could be made, there might be clear indications for operative intervention to cure the disease. In complicated cases a thorough search through a proper sized opening should be made to terminate the symptoms, establish of and a record of all findings made for future reference.

**Torsion of the Omentum.**—Dr. W. W. GRANT

of Denver, reported an interesting case of torsion of the omentum, and said that in view of the most common association of this diseased condition with hernia, it became a matter of unusual interest in this particular case as to its possible connection with hernia in earliest childhood. He was positive, from the nature and character of the adhesions, the condition of the intestine, and the absence of any indication of disease, past or present, of every other organ or part, that it was of long standing. It seemed possible that it could have dated from the existence of hernia in childhood without causing intestinal obstruction or torsion at an earlier date. The vomiting might have been due to a momentary obstruction from volvulus due to the adhesion and intestinal peristalsis.

In reviewing the literature, Dr. Grant found that sixty-one cases had been reported. He agreed with Richardson, of Los Angeles, that strangulation of the omentum from pressure or adhesions did not constitute torsion and should not be classed as such. Only seven cases were entirely intraabdominal. His own made eight. The torsion might be single or double, but usually the former. In the intraabdominal cases the symptoms closely resembled those of acute appendicitis, and up to the present time there had probably been a diagnosis of the latter. Even in hernia the abdominal symptoms were pronounced in most cases. The tenderness and dulness at an early period covered a wider area than in appendicitis; yet, if on the right side, both subjective and objective symptoms simulated those of acute appendicitis. If hernia existed, one should especially be on guard as to the diagnosis. The history of torsion of the greater omentum justified this precautionary statement, and he hoped that these suggestions might be accepted as timely. He believed this case was unique in the fact of a portion being completely amputated by torsion from the body of the omentum and fixed by adhesion to one point of intestine and to nothing else.

**Lymphatic and Portal Infections Following Appendicitis.**—Dr. ROLAND HILL, of St. Louis, reported an interesting and unique case illustrating these infections, and said that in the present stage of surgical knowledge we were almost absolutely helpless in the presence of some of the severe forms of infection when the infecting organism had once passed into the general circulation. It went without saying that early removal of the appendix should be the keynote in all cases, together with an attack, whenever possible, upon any focus that might form. Considering what had been accomplished along the lines of serum therapy, the remarkable effects of antitetanic serum as a prophylactic of tetanus, and the miraculous results of diphtheria antitoxine, it did not seem too much to hope and expect that experimental medicine would soon offer specific agents which would nullify the effects of the various pathogenic organisms when once they had been introduced into the blood.

**Extrauterine and Intrauterine Pregnancy of Five Months, with Operation and Death.**—Dr. D. C. BROCKMAN, of Ottumwa, Iowa, reported the case of a woman, five months pregnant. An attempt was made to remove the ectopic sac by abdominal section, but the parts were so vascular that he was

obliged to desist. Furthermore, the patient was so debilitated from vomiting that he did nothing further. But in ten days he opened the sac from below, removed the fetus, and packed the cavity with gauze, intending to remove the placenta later. Uterine hemorrhage and pains occurred on the third day, and the woman died two days later from extrauterine and uterine hemorrhage. He asked whether a better method could be suggested.

Dr. D. W. BASHAM, of Wichita, Kan., reported a case of hernia of the appendix, which was complicated with appendicitis, and reviewed the literature on the subject.

**Sexual Perversion as an Accompaniment of Prostatic Hypertrophy.**—Dr. J. F. PERCY, of Galesburg, Ill., believed that the old prostatic, who showed aberrant sexual activity, was in a large proportion of cases suffering from a psychosis rather than senile dementia, to which the symptoms were usually attributed. Under the influence of the irritation from his enlarged prostate he might commit all forms of sexual crime, and after removal of his prostate his functional sexual aberration disappeared and he remained cured. This phase of the diseased prostate opened up the possibility of a more rational study of the pelvic environment of the prostate gland in the sexual perversions among men, old and young. Many old prostatics were in insane asylums and many of them were in the Government and State soldiers' homes, as well as in the various county almshouses. The strain of sexual excesses from early life until old age, the intimate connection maintained between the prostate gland and the sympathetic and the cerebrospinal nerves, the unknown secretory functions of the prostate gland along physiological lines—these all made prominent the fact that with the hypertrophied prostate could be had a class of symptoms referable to the sexual system where the mental life of the sufferer carried him close to the border where insanity had its dominion, and which could be corrected by the aid of surgery.

**Intestinal Obstruction.**—Dr. B. MERRILL RICKETTS, of Cincinnati, contributed a paper on this subject, in which he defined obstruction as the stoppage or blocking of a canal or opening in the body, due to any of the numerous causes. The symptoms, such as vomiting, pain, distention (symmetrical or asymmetrical), sweating, collapse, rigid parietes, and toxemia, one or all, might be present in any form of obstruction in the large as in the small bowel. These being facts, why should exploration be delayed, when simple incision through the abdominal wall was done without mortality? Should exploration and direct digital and ocular examination of the abdominal viscera be delayed in intestinal obstruction, because experiments, reports, "symposia," and discussion had failed to explain satisfactorily its aetiology, symptoms, and treatment? Intestinal obstruction probably had a higher immediate mortality, with or without surgical intervention, than any of the surgicopathological diseases. The nonmechanical type without operation had a supposed mortality of ninety per cent. when not complicated with general peritonitis, and from sixty to eighty-four per cent. with operation. This mortality in postoperative obstruction exceeded that

of preoperative obstruction of the same degree, whether of the mechanical or nonmechanical or septic type. This increased mortality was due to the added surgical trauma, and especially to the anæsthetic. In the mechanical type the mortality was given as one hundred per cent. without operation, and from fifty to eighty per cent. with operation. This difference was probably due to the advantages of palpation and the Röntgen ray in detecting neoplasms and foreign bodies, which were its most common cause; hence earlier surgical measures might be resorted to. In the septicoperitonitic type without operation the mortality was generally given as one hundred per cent., while with operation it was somewhat less. There were certain forms of obstruction with or without infection that had been considered invariably fatal. If this was so, there was nothing to be lost in opening the abdomen. If, after opening the abdomen, an imperfect mechanism within could be made perfect without destruction of the nerve or blood supply, in the absence of infection, surely many more patients would recover; even with many forms of infection this was probably so. But if the patient became exhausted from vomiting, pain, or want of nourishment, with or without infection of any kind, the mortality would be proportionately high. Pain, distention, and vomiting were always alarming, and the majority of patients went on to death in spite of every effort to relieve them. Intoxication had not yet been proven to be the cause of death in any given case of obstruction. If patients with obstruction indicated by one or more symptoms were opened at the onset, under ordinary precautions, the mortality would be less than if they were operated upon late in the attack. The element of delay in surgery was more serious than the element of aggressiveness. In no other surgical condition was this statement more fully verified. The most skilled operators had many times opened the abdomen for a condition made apparently certain by one or more symptoms, and found one entirely different. If this was sanctioned in other lesions of less importance within the abdominal cavity, why could not exploration for obstruction based upon one or more symptoms be undertaken? This would determine the character and degree if obstruction was present. If it was not present no special harm would ensue. If the character or degree or both were believed to be fatal, the remedy should be applied, regardless of its character, because that verdict was only an opinion, not an established fact.

Dr. A. A. KERR, of Salt Lake City, contributed a paper in which he discussed obstructions of the common bile duct, and reported a case in which he performed cholecystostomy, partial gastrectomy with posterior gastrointestinal anastomosis, cholecystenterostomy, and enteranastomosis.

The following officers were elected for the ensuing year: President, Dr. W. W. Grant, of Denver; vice-presidents, Dr. Willard Bartlett, of St. Louis, and Dr. Harry A. Sifton, of Milwaukee; secretary-treasurer, Dr. Arthur T. Mann, of Minneapolis; executive council, Dr. C. H. Mayo, of Rochester, Minn., and Dr. J. F. Perry, of Galesburg, Ill.

Minneapolis was selected as the place for holding the next annual meeting, on December 29 and 30, 1908.

## Book Notices.

*[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]*

**Maternity.** By HARRY D. FRY, M. D., Sc. D., Professor of Obstetrics, Medical Department of the Georgetown University, etc. New York and Washington: Neale Publishing Company, 1907. Pp. 220.

This book seems to be intended primarily for the laity. Its teachings are sound in the main, and the author's style is agreeable; consequently, it is likely to be of real service to many women, provided they do not accept it as embodying "the truth, the whole truth, and nothing but the truth," as the laity are very apt to do. Such implicit acceptance of any medical writing is apt to make the reader think he knows all about the subject and to render him contentious in his intercourse with the physician. A general precept has often to be fitted to the case in hand, and this the laity rarely comprehend.

The book treats of hygiene in its particular application to the female sex, with special attention to menstruation, pregnancy, and childbirth, dealing also with the care of infants.

**Outlines of Psychiatry.** By WILLIAM A. WHITE, M. D., Superintendent of the Government Hospital for the Insane, Washington, D. C., etc. New York: The Journal of Nervous and Mental Disease Publishing Company, 1907.

In publishing this book the author disclaims any intention of offering a substitute for larger and more pretentious works. He will have it that he is merely providing a "helpful guide" for his students and a working knowledge for young physicians. This is modest, but we believe that, whatever his conscious purpose may have been, the author has wrought more deeply than he thought. To give a working basis for the student of mental diseases, that is, to provide him with such matter and manner of thought as will lead to the acquisition of the power of independent observation and logical interpretation is scarcely a light undertaking. To a science like morbid psychology, involving at every turn a comparison of pathological mentalization with the normal operations of the mind, the task of laying down adequate principles is beset with manifold difficulties; and, furthermore, when it is borne in mind that many who read are by nature inept, being but poorly provided with the faculty of subjective analysis, the wonder is that any can be found among us with sufficient powers of exposition to reach the comprehension of the average mind. Yet we believe that Dr. White has succeeded; that he has written a book of manifest helpfulness to those desirous of going about the study of mental diseases in a systematic and rational manner, and that no student can read his book thoroughly without gaining a point of view which, with the aid of subsequent cultivation and experience, will confer a sense of capacity—more or less according to original endowment—for independent and useful observation.

The author prefaces his treatise with a brief chapter on the nature of the human mind. This is satisfactory, but we believe that the accuracy of psychical operations could have been appreciably lengthened without detriment or interference with the general plan of the book. Upon this follow ten

givings on the definition of insanity; classification of mental disorders; the causes of mental disorders and their treatment; and then two rather lengthy chapters on symptomatology and the examination of the insane. The last named chapter is admirably done; and even though all the tests are not always applicable, and a few of them perhaps debatable, most of them are well conceived and obviously informing.

Likewise to be commended are the chapters on Dementia Præcox, Paranoia and Paranoid States, and Manic-Depressive Psychoses.

The author acknowledges his indebtedness to Dr. Smith Ely Jelliffe for valuable hints and to Dr. Shepherd Ivory Franz for the preparation of the substance of Chapter VII—that on the examination of the insane, to which we have already favorably adverted.

*Notwendige Reformen der Unfallversicherungsgesetze.* Nach einem auf der Wanderversammlung der südwest-deutschen Neurologen und Irrenärzte in Baden-Baden am 1. Juni, 1907, erstatteten Referate. Von Prof. Dr. A. Hosne, Freiburg, i. Br. Halle a. S.: Carl Marhold, 1907.

The German laws referring to accident insurance, which force every employee to be insured and every employer to insure his help, was made the subject of a dissertation by the author at a meeting of the Society of Southwest German Neurologists, held in Baden-Baden on June 1, 1907. He points out several features of the laws which should be changed from the viewpoint of the neurologist.

#### BOOKS, PAMPHLETS, ETC., RECEIVED.

Die Schuppenflechte (Psoriasis vulgaris) und ihre Behandlung. Von Dr. S. Jessner, Königsberg i. Pr. Zweite Auflage. Würzburg: A. Stuber, 1908. Pp. 39. (Price, 70 marks.)

Annual Report of the Board of Trustees of the German Hospital and Dispensary in the City of New York for the Year 1907. Pp. 100.

Geschichte der Laryngologie in Würzburg. Von Professor Dr. Otto Seifert, Würzburg. Würzburg: A. Stuber, 1908. Pp. 68. (Price, 3.50 marks.)

Fourth Annual Message of John Weaver, Mayor of the City of Philadelphia, with the Annual Reports of the Director of the Department of Public Health and Charities and Chief of the Bureau of Health, for the Year Ending December 31, 1906. Issued by the City of Philadelphia, 1907. Pp. 236.

Textbook of Otolaryngology for Physicians and Students. In Thirty-two Lectures. By Fr. Bezold, M. D., Professor of Otolaryngology at the University of Munich, and Fr. Siebenmann, M. D., Professor of Otolaryngology at the University of Basle. Translated by J. Holinger, M. D. of Chicago. Chicago: F. H. Colgrove Co., 1908. Pp. 314.

Bericht über den XIV. internationalen Kongress für Hygiene und Demographie, Berlin, 23-29 September, 1907. Band I. Berlin: August Hirschwald, 1908. Pp. 314.

#### Miscellany.

**The Plan of the Campaign Against Tuberculosis.**—Much has been said of late in the press concerning the campaign for the prevention of tuberculosis which has been inaugurated by the State Charities Aid Association. The press has indeed been, as it always is, most generous in giving to this movement the full and complete publicity which is indispensable to any effective work of a broad educational nature. Some few misconceptions, however, have become current. Chief among these is the fact that people have been led, through a misinterpreted newspaper report, to believe that a million dollars has been donated for the purpose of conducting this campaign, and that therefore the localities in which the educational campaign is being conducted are to assume no responsibility so far as financial support is concerned. In the light of this report it may be well to state definitely the plan and method of the State Charities Aid Association in this movement. The association is not merely spending money in arousing a wave of sentiment without a permanent basis in fact. On the contrary, the educational movement in any given locality is not begun until the facts concerning the disease are well known. This knowledge is obtained by means of an extended and thorough investigation: First, of the vital statistics, in order to determine the exact death rate and the prevalence of the disease; second, as to the provisions for relief and care of needy consumptives; third, as to the preventive measures that are in force; fourth, as to the means which are employed for acquainting the wage earners and the people in general with the present knowledge as to the treatment of pulmonary tuberculosis; fifth, as to general hygienic measures having special value in the prevention of tuberculosis, such as the adequacy of the building code, of supervision of food supplies, of supervision and regulation of public lodging houses, etc. It is not until after the investigation has revealed all the facts touching upon these points that the active part of the educational campaign in any given locality is undertaken. It is then that the series of public meetings is held, in connection with the tuberculosis exhibition of the State Department of Health and the facts concerning the means of prevention, treatment, and cure of this terrible disease are as widely disseminated as possible, and sentiment aroused through the aid of the press. And all this is done only for the purpose of directing the interest and enthusiasm thus aroused into definite channels of action, which will result in a material saving of life in each community. At the close of this active educational campaign a local committee of the State Charities Aid Association is formed for the purpose of continuing the work of education and securing the adoption of definite measures for the prevention of this dread disease. **Public Health and Marine Hospital Service:**

*Official list of changes of stations and duties of commissioned and noncommissioned officers of the United States Public Health and Marine Hospital Service for the seven days ending March 4, 1908:*

COMFORT, N. C., Pharmacist. Directed to report to Passed Assistant Surgeon V. G. Heiser, chairman of a board of examiners, to determine his fitness for promotion to the grade of pharmacist of the second class.

EARLE, B. H., Passed Assistant Surgeon. Granted leave of absence for five days, from March 2, 1908.

FOSTER, M. H., Passed Assistant Surgeon. Leave of absence granted for two months and eleven days, from October 9, 1907, amended to read two months and nine days.

KEATLEY, H. W., Acting Assistant Surgeon. Granted leave of absence for five days from February 26, 1908.

KEEN, W. H., Pharmacist. Granted leave of absence for twenty days, from March 6, 1908.

SCOFIELD, R. B., Passed Assistant Surgeon. Granted leave of absence for three days, from February 23, 1908, under paragraph 191, Service Regulations.

*Board Convened.*

A board of medical officers was convened to meet in Manila, P. I., upon the call of the chairman, to examine Pharmacist N. C. Comfort for promotion. Detail for the board: Passed Assistant Surgeon V. G. Heiser, chairman; Passed Assistant Surgeon T. B. McClintic, recorder.

**Army Intelligence:**

*Official list of changes in the stations and duties of officers serving in the medical department of the United States Army for the week ending March 7, 1908:*

BANTA, W. P., Captain and Assistant Surgeon. Advanced to the rank of captain, from February 18, 1908.

BIRMINGHAM, H. P., Major and Surgeon. Now on duty as medical inspector, Army of Cuban Pacification, will report in person to the commanding general of that Army for duty as chief surgeon, relieving Lieutenant Colonel Blair D. Taylor, deputy surgeon general.

LEGARDE, L. A., Lieutenant Colonel and Deputy Surgeon General. Upon arrival in the United States will proceed to Denver, Colo., and report in person to the commanding general, Department of the Colorado, for duty as chief surgeon of that department.

MABEE, J. I., First Lieutenant and Assistant Surgeon. Ordered to report in person on Tuesday, March 24, 1908, to Lieutenant Colonel George H. Torney, deputy surgeon general, president of examining board, Presidio of San Francisco, Cal., for examination to determine his fitness for advancement.

SCOTT, G. H., Captain and Assistant Surgeon. Ordered to report in person on Tuesday, March 24, 1908, to Lieutenant Colonel George H. Torney, deputy surgeon general, president of examining board, Presidio of San Francisco.

SCOTT, G. H., Captain and Assistant Surgeon. Relieved from further duty at Fort Duchesne, Utah, and assigned to permanent station at Fort Logan, Colorado.

TAYLOR, B. D., Lieutenant Colonel and Deputy Surgeon General. Relieved from further duty at the Army and Navy General Hospital, Hot Springs, Ark., and upon his relief from duty as chief surgeon, Army of Cuban Pacification, will proceed to Atlanta, Ga., and report to the commanding general, Department of the Gulf, for duty as chief surgeon of that department.

VAN DUSEN, J. W., Captain and Assistant Surgeon. Now on leave of absence at Norwalk, Ohio, will proceed on or before the expiration of said leave to Fort Crook, Neb., for duty.

**Navy Intelligence:**

*Official list of changes in the medical corps of the United States Navy for the week ending March 7, 1908:*

GARDNER, J. E., Medical Inspector. Ordered to the marine recruiting station, Boston, Mass.

HULL, N. F., Passed Assistant Surgeon. Commissioned a passed assistant surgeon from April 12, 1907.

MCDONELL, W. N., Passed Assistant Surgeon. Detached from the naval recruiting station, Chicago, Ill., and ordered to the *Hancock*.

PUCK, R. F. S., Pharmacist. Appointed a pharmacist from February 24, 1908.

THOMPSON, J. C., Surgeon. Ordered to report at Washington, D. C., to the Secretary of War, for special duty.

WHEELER, L. H., Passed Assistant Surgeon. Commissioned a passed assistant surgeon from April 22, 1908.

**Births, Marriages, and Deaths.***Married.*

BACHMAN—LESSIG.—In Pottstown, Pennsylvania, on Wednesday, February 26th, Dr. Morton V. Bachman, of Philadelphia, and Miss Caroline Bleim Lessig.

HAMMEREL—WOLF.—In Stillwater, Minnesota, on Wednesday, February 26th, Dr. Ambrose Louis Hammerel and Miss Anna Martha Wolf.

SCHISLER—CHIPLEY.—In St. Louis, Missouri, on Monday, February 24th, Dr. Edwin J. Schisler and Mrs. Lily Chipley.

*Died.*

CHAMBERLAIN.—In Madanapalle, India, on Monday, March 2d, Dr. Jacob Chamberlain, of New Brunswick, New Jersey.

DUFLOO.—In New York, on Saturday, February 29th, Dr. Armand L. F. Dufloo, aged seventy-five years.

EATON.—In Des Moines, Iowa, on Thursday, February 27th, Dr. Charles W. Eaton, aged fifty-two years.

GREENWALD.—In Philadelphia, on Wednesday, February 26th, Dr. Daniel F. Greenwald, aged fifty-five years.

HUGHES.—In New Rochelle, New York, on Thursday, March 5th, Dr. Oliver John Davis Hughes, aged fifty-five years.

LUEDEKING.—In St. Louis, Missouri, on Saturday, February 29th, Dr. Robert Luedeking, aged fifty-four years.

MACLAY.—In Chambersburg, Pennsylvania, on Tuesday, March 3d, Dr. David MacLAY, aged fifty-six years.

RING.—In Olcott, New York, on Saturday, February 29th, Dr. Charles A. Ring, aged fifty-four years.

ROOSA.—In New York, on Sunday, March 8th, Dr. Daniel Bennett St. John Roosa, aged sixty-nine years.

#### PROGRESS IN GYNÆCOLOGY FROM A CLINICAL VIEWPOINT.\*

By H. J. BOLDT, M. D.,  
New York.

While the advances made in gynæcology during the last few years are not so numerous as in some other departments of medicine, yet they are of sufficient importance to be noted.

Time was, not so many years ago, when it was a common occurrence to have an abundant number of uterine appendages that were practically normal presented at medical meetings and exhibited by the operator as trophies of his skill. Most of the patients recovered from the operation, it is true, but what was their physical condition subsequently? The greater number were not benefited at all; many of them were made much worse, while only a comparatively few were made better. When we seek for a reason for these unsatisfactory results, we are inevitably brought to the conclusion that the indication for the operation was based upon poor judgment; that in reality it did not exist at all. Physicians of many years' experience have passed the operating furor, and their judgment has been improved by experience, although it has not become perfect. In those days fifty per cent. of the cases of pelvic pain without gross palpable lesion in the pelvis were ascribed by the operating gynæcologist to an inflammation of one or both ovaries, the removal of which was deemed necessary to effect a cure. The tubes were said to be inflamed, whereas in reality, from a strictly pathological viewpoint, they were normal or very nearly normal.

Following the period of indiscriminate extirpation of the pelvic organs, there comes a period of ultra-conservatism, and though conservative procedure sometimes acts to the detriment of our patients, it has even then this advantage over radical surgery, that if the conservative operation does not bring about a symptomatic cure, a radical operation may subsequently be done.

Let me illustrate by an example: Take a patient with bilateral pyosalpinx of the chronic variety. Nearly all such patients have a chronic metroendometritis, and it is safe to state that they are sterile. From a theoretical point of view, such pelvic organs are useless to the patient. If she is advanced in years, near to the climax, and if the symptoms arising from the diseased local condition indicate surgical intervention, then the only

correct procedure is to do a radical operation—that is, remove the uterus with its annexa. If, however, the patient is in her thirties, or even younger, the psychical effect of such an operation is likely to be very severe. In the latter case, then, it is better to excise the Fallopian tubes, and if a zone of seemingly normal ovarian stroma is still present, to excise also the diseased area of ovarian tissue, and to implant the apparently normal part into the uterine cornu, from which the interstitial part of the tube also should have been excised. Subsequently, the cure of the metroendometritis by means of local treatment may be attempted. With such operation psychical disturbances are avoided. Should it be shown, after a sufficient time has elapsed, that the patient is not cured, then we may resort to a radical operation.

The greater conservatism of operating on the pelvic organs is also exemplified when operating for tubal pregnancy. While most operators still follow the old method of removing the entire annexum of the affected side, a considerable number have given that up and are content to remove only the Fallopian tube, retaining the ovary; while under favorable circumstances, some operators are still more conservative, and content themselves with splitting open the affected tube and depriving it of the conception product.

On this kind of conservatism of the pelvic organs I think most of the gynæcological operators of experience are agreed. It is not so, however, with conservative operations in multiple myomata. While the procedure has been tried frequently, the results are so far from satisfactory that we are still on the line of experimentation. With pedunculated tumors and single interstitial tumors of moderate size, we have passed the period of experimentation, and can with safety do a myomectomy.

With regard to myomatous tumors, we are learning more from year to year, and are realizing that they are not so innocent as we formerly thought them to be.

In operations for cancer of the uterus we have done much to advance the curability of the disease by doing the operation more radically, not relying upon the extirpation of the affected organ alone, but going beyond the boundaries of the organ and excising the parametria and the adnexa, and in some cases, even a part of the bladder.

Whether the longevity of patients afflicted with carcinoma of the cervix is increased by such procedure, has not yet been settled. It does not seem possible to remove all the pelvic and retroperitoneal glands. While I have done the operation,

\*Read at the Twentieth meeting of the New York Academy of Medicine.

number of times, I am not yet favorably impressed with it, both because of the magnitude of the surgical intervention, and because, in my opinion, it is impossible to remove all the invaded glands. About five years more of work in this direction should determine the mooted point.

Our knowledge of chorioepithelioma may be classed among the late achievements in gynecology. The first description of this malignant disease was given by the late Martin Saenger. Since he called the attention of the profession to this occasional transformation of conception product structures, many exhaustive and valuable articles on this comparatively new disease have appeared, and we have learned to recognize it sufficiently early to save many lives by immediate radical surgical intervention.

Very marked progress has been achieved in the treatment of purulent peritonitis. It has been proved by those who have tried the more modern method of extensive nonintervention that the rate of mortality is much lower. After the primary cause of the peritonitis has been removed, no attempt should be made to rid the abdominal cavity of the purulent secretion by flushing and sponging, because to remove it all is impossible, and the time consumed in flushing and sponging is too long and the traumatism too great. One should content himself with placing a drain in the cul-de-sac of Douglas, without any flushing or sponging. Rapid work is essential. When the patient is put to bed she should be placed in a semisitting position, the position suggested by the late Dr. George R. Fowler.

From that time on, continuous instillation of saline solution should be used, a method advocated by Dr. J. B. Murphy. It is certainly marvellous what a large quantity of fluid is absorbed. I have found that the best technique consists in taking an ice water cooler of two or three gallons' capacity, filled with hot saline solution (0.9 per cent.). This is kept at a temperature of about 110° F. by adding more very hot solution as needed. The quantity so added should be noted, so that we may know how much the patient absorbs. The container is placed alongside the bed and the rubber tube, with a small-sized rectal point, is attached. The flow is regulated by the faucet, and should not be more rapid than a quick dropping. The nozzle is inserted into the rectum, and the instillation is continued steadily, day and night. In one of my cases fourteen quarts were absorbed in twenty-four hours.

We have also learned by experience that, in instances of cystocele associated with descent of the anterior vaginal wall, a simple operation on the vaginal mucosa, such as some form of anterior colporrhaphy, does not suffice to cure a patient of the cystocele, but that it is necessary to separate the bladder from its cervical attachment and displace it upward, and then attach the vagina to that part of the cervix to which the bladder had been previously attached.

It would take more time than that allotted on this occasion were I to consider also the strictly scientific progress made in gynecology, and to consider in detail all of the clinical advances. I have, therefore, limited myself to those achieve-

ments which I consider most important and bear strictly on gynecology.

## POINTS IN THE EARLY DIAGNOSIS OF PULMONARY TUBERCULOSIS.\*

By EMMET KEATING, M. D.,

Chicago,

Clinical Assistant, Department of Medicine, Rush Medical College;  
Physician to the Swedish Baptist Home for the Aged,  
Morgan Park.

Medical society discussions of the subject of pulmonary tuberculosis indicate that it is difficult for many physicians to erase from their minds the clinical picture of what was formerly conceived to be an early diagnosis of this disease. Teachers in medical schools soon learn that students are least proficient in those subjects of which they have heard most, prior to their routine consideration. It seems that the exhaustive studies and discussions of the subject, that have filled the medical journals, while they have been of immense profit to those who are especially interested, have failed to impress the majority, who mistakenly infer that there is nothing more to be learned of a disease of which so much has been said and written. The *Bulletin of the Chicago Department of Health* states that for the week ending December 7, 1907, seventy-four people died from pneumonia, and seventy-seven died from various forms of tuberculosis. These figures do not indicate very startling progress in the prevention and cure of tuberculosis.

Although the pathologists have been demonstrating the almost universal prevalence of tuberculous lesions in adults that come to autopsy, we are slow in understanding that it is not the presence of tuberculous foci that should be cause for alarm, but the manifestation of the infection that should demand prompt and decisive action. When it is fully appreciated how slowly the disease progresses in its incipency, how grudgingly the organism yields to the invasion and with what readiness favorable reaction occurs, the number of cases of quick consumption will dwindle to a small minority, and we will find little solace in the thought that death in these cases is inevitable.

The mistaken belief that the tubercle bacillus must be found in the sputum before a diagnosis can be made is responsible for lack of care in clinical examination, errors in diagnosis, and unnecessary delay in the institution of proper treatment. It is quite true that if the patient recovers there is no positive evidence that the illness was due to tuberculosis; but if sufficient care has been exercised to rule out other diseases such a diagnosis is justifiable.

Clinical ability is largely proportionate to a knowledge of pathology, but the ambition to have diagnoses confirmed at the autopsy table is not always conducive to close and careful study of patients, nor to the making of efforts to effect a cure. If sputum can be obtained it should be examined in all cases, but the examiner should keep in mind that a negative sputum may be demonstrated from a victim of

\*Read before the North West Suburban Branch of the Chicago Medical Society, Newwood Park, Ill. December 9, 1907.

pulmonary tuberculosis, as well as a negative urine from a case of nephritis. Bacteriological studies have made possible the diagnosis of pneumococcus infection, when lung symptoms are wanting; but as it is seldom convenient to make the cultures to prove its existence, the clinical diagnosis is made. If the sputum examination offered as many difficulties as the recovery of the pneumococcus from the blood, more skill in the way of clinical recognition would be developed. Dr. Herrick has told us that "the physician has no right to throw the entire responsibility of an important decision upon the laboratory" (1). The value of the laboratory findings in any disease process should not be minimized, but these findings are but a part of the evidence, and the correlation with the clinical picture is a necessity in arriving at a correct conclusion. It is entirely possible to make a diagnosis of pulmonary tuberculosis before the condition is suspected by either the patient or his associates. The prospect of cure and the difficulties involved in the treatment of fairly well advanced cases do not admit of delay in recognizing the disease.

"Cambridge found bacilli in the sputum of 866 cases out of 925 (63.6 per cent.); and Lawerson Brown, who frequently made more than one examination for the same patient, found them in forty-two out of ninety incipient cases (46.7 per cent.); and in eighty out of eighty-seven moderately advanced cases (92 per cent.); Turban found tubercle bacilli in the sputum in 325 out of 408 patients (79.9 per cent.), during the course of the disease; and, according to stages, in thirty-seven out of ninety-seven cases (37.5 per cent.) in the first stage; in 184 out of 205 cases (89.9 per cent.) in the third stage. Julius Nagel found tubercle bacilli in 161 out of 1,081 female patients (14.9 per cent.); in eleven out of 762 cases (1.4 per cent.) in the first stage; one hundred out of 264 cases (38 per cent.) in the second stage; and in fifty out of fifty-five cases (91 per cent.) in the third stage. Nagel asserts that on account of the weaker muscular expiratory mechanism in women the chance of finding tubercle bacilli in the sputum of women is less than it is in men. They are also said to swallow their sputum more than men. From statistics of several different German sanatoriums, from records made on admission, I find that out of 3,429 patients with expectation, 1,351 (39.4 per cent.) showed tubercle bacilli; 438 out of 1,555 (28.2 per cent.) in the first stage; 225 out of 705 (31.9 per cent.) between the first stage and second stage; 302 out of 612 (49.3 per cent.) in the second stage; 176 out of 278 (63.3 per cent.) between the second and third stage; 209 out of 276 (72.1 per cent.) in the third stage; and out of three in which the stage was not recorded, 2. It is made presumed that care was exercised in obtaining the sputum for these statistics, and that the compilers were skilled in the use of the microscope. They are in accord with the experience of any physician who has kept records of his patients, and has had the opportunity to follow the subsequent history of those in whom he suspected pulmonary tuberculosis at the first examination.

A careful and searching history should be obtained (2). Fear of the incurability of the disease

has been so firmly impressed upon the minds of most persons that admission of the disease in members of the family is evaded. If the patient suspects the presence of the infection in his own case he not infrequently becomes reluctant and aggressive if the line of questioning suggests that the examiner has in mind the possibility of tuberculosis. Denial of facts and conditions is not uncommon. Diseases of childhood are easily overlooked if the offhand thoughtless disclaimer of the patient is at once accepted. The occurrence of these infections are important in that conditions are established that render the tissues of the child susceptible to the implantation of the tubercle bacillus, which may become a menace in after years. Of importance is the past and present association with others suffering from tuberculosis. The occupation may be a causative factor, but no trade or profession is exempt. Inquiry should be made as to the manner of living, worry, overwork, or a too zealous devotion to social duties, which results in a nervous breakdown. Does the bedroom receive fresh air? Is the window kept open at night, and how much? An inch or two is not enough. How does the patient eat? Is it coffee and rolls for breakfast, a starvation lunch at noontime, and a fifteen cent dinner in the evening? Has the patient, misled by the stomach symptoms, been indulging in a light diet, which further impairs the nutrition and serves to aggravate the distressing hyperchlorhydria that is often present? These are common conditions found daily in clinic and office, and merit more attention than they have received. Slight hæmoptysis may have occurred months and even years before the patient comes under our observation. Night sweats are found to have occurred at different times in many cases. It has been stated that those children whose heads sweat profusely when they are asleep are almost always subjects of tuberculous infection (4). Patients who have pulmonary tuberculosis tire easily, especially in the afternoon.

The expression of the face is often significant, sometimes worried and anxious, sometimes discouraged and apathetic. A slight degree of dependency is generally apparent. The feet and hands are cold and clammy. Emaciation is not a feature of an early case. The red line of the gums at the margin of the teeth was noted fifty years ago. A number of decaying teeth may be considered both as a cause and a result of tuberculosis. In many cases the tonsils are chronically inflamed, and the larynx presents a pale and anemic appearance. If emaciation is not present, the chest will not have the phthisical appearance described in the textbooks. When this condition is found, no other disease process being present, it may be generally set down that the case is well advanced. Subclavicular retraction will be noted in many cases, but may be of slight degree. Expansion is apt to be limited, as many of these patients are shallow breathers. Undue prominence of the scapulae is not seen in those patients who have lost but a small amount of weight. Changes in vocal fremitus cannot be expected where the involvement of lung tissue is so slight as to make it difficult to know from these findings that tuberculosis is the disturbing factor.

When the infection first becomes apparent

extremely difficult in many patients to determine the existence of the process by the chest findings alone, or to decide whether we are dealing with a simple bronchitis, a slight bronchopneumonia, or a healed lesion. With a simple bronchitis of small degree there is not apt to be any disturbance of other organs that are manifest either to the patient or to the physician. When tuberculosis is present, the examiner will be able to find pathological or functional changes in other organs, produced by the lung infection. Early in the infection the lung findings can only be considered as confirmatory evidence of pulmonary tuberculosis. Pleurisy has been considered positive evidence of tuberculosis, but I do not believe it to be an initial symptom, as I have not found symptomatic or physical evidence of it in beginning cases. Pain in the region of the heart is often the only one of which the patient complains.

When the process is sufficiently advanced to present physical signs, a slightly higher percussion note is detected, which extends from the apex to the upper border of the second rib. In slight variations of the percussion note the examiner should strike eighteen or twenty blows with the percussion hammer instead of the customary three or four. Not infrequently the patient will complain of pain within the chest beneath the area being percussed. Over this area the stethoscope will show an inspiratory sound that is sometimes harsh and sometimes jerking in character. Care in listening will demonstrate slight prolongation of the expiratory murmur. Râles, either dry or moist, are seldom heard. Râles that are difficult to elicit can be heard more plainly if the patient is instructed to breathe deeply several times in succession. If it is desired to demonstrate bronchial breathing, rather shallow, rapid breathing is most effective.

Posteriorly, the higher percussion note will be found as low as the spine of the scapula. The abnormal breath sounds heard beneath the clavicle are here more pronounced, and pectoriloquy may be noted as low as the fourth rib. In uncomplicated cases no change in size or position of the heart can be demonstrated. There is always a degree of tachycardia present, and an increased force to the contraction of the organ. Aside from the pain caused by a gas distended stomach, there is nothing either clinically or pathologically to account for the pain in the heart region complained of by the patient. The examination of the abdomen may be entirely negative, but pressure over the stomach will, in the majority of cases, elicit pain. In more advanced cases almost the entire abdomen may be sensitive to pressure; and in the female the tubes and ovaries will be found quite sensitive. Menstruation is not often affected; if the function should be altered it seldom has any bearing on the case, as the flow not infrequently continues until a short time before death. The pulse and temperature are important features, the afternoon temperature of most significance being 99° F.; a pulse rate of 80 or a trifle higher will be found both morning and afternoon.

## THE TREATMENT OF ECZEMA IN INFANTS AND YOUNG CHILDREN

By JAMES M. WINFIELD, M. D.

Brooklyn, N. Y.,

Professor of the Diseases of the Skin in the Long Island College Hospital, etc.

It is with considerable hesitancy that I present this paper before a society composed of members skilled in the treatment of diseases of children. For the subject of eczema is so vast, and so many points require consideration, that it is difficult to choose which ones to touch upon in a paper that must be limited by lack of time.

Of all the cutaneous diseases, eczema is the most important, for it, in some of its protean forms, constitutes about one third of all of the skin diseases treated in the dermatological clinics of the world.

It is of common occurrence among infants and young children, and often proves extremely difficult to handle; many factors must be taken into consideration before one can expect to accomplish a cure.

Eczema is a catarrhal dermatitis, and if the typical symptoms of redness, swelling, vesiculation, and exudation are marked the diagnosis is a comparatively easy matter; but if there should be any variation from type the diagnosis may become difficult.

It is unfortunate for any one who is not a cutaneous specialist that writers upon skin disease have seen fit to multiply adjectives in attempting to describe the clinical types of eczema; the essential point to remember is that the treatment must be appropriate for a catarrhal skin disease that may be acute, subacute, or chronic.

These terms, acute, subacute, and chronic, should be understood to indicate the grade of inflammation, rather than the length of time the eruption has existed.

Infantile eczema is usually acute or subacute; when acute it is attended with redness, heat, and swelling; when chronic these conditions have, to a great extent, subsided, and the skin is considerably thickened.

Acute eczema frequently runs a typical course of three stages. First, the stage of congestion, erythema, and vesiculation; second, weeping and crusting; and, third, the stage of resolution by desquamation.

Owing to the thin and sensitive epidermis of the young, the vesicular stage may not be present, or if it is it is very transitory, and the picture first seen by the physician is the raw, red, exuding, and crusted surface. This condition is brought about by an intense effusion of serum underneath the epidermis, which washes it away in mass.

It occasionally happens that the effusion is very slight, and the congestive stage is rapidly followed by the squamous.

Read before the Scientific Section of the Medical Society of the County of Long Island, 1907.

The four types of eczema that are of special interest to those who treat diseases of children are the erythematous, the papulovesicular, pustular, and squamous.

Erythematous eczema is usually dry, and is the mildest form that children have: it is often described under the name of pityriasis; it is more frequently seen upon the face and hands, appearing, in some instances, as a simple chapping of the skin. It is also quite common to see erythematous eczema occur, in small rounded spots, scattered over different parts of the body. Although, in the adult, this variety is characterized by intense itching, in children this subjective symptom is comparatively slight.

The papular variety, eczema papulosum, the lichen simplex of the older writers, is observed in childhood; it usually appears on the flexor surfaces of the body as discreet, or numerous, irregular groups of bright red, acuminate papules, which, from the scratching, are tipped with minute blood crusts; if the disease becomes at all chronic the groups run together and are converted into thickened, scaly, or crusted patches.

The vesicular variety, eczema vesiculosum, is the most typical expression of the disease, and in infants is generally seen upon the face.

In the vesicular form the duration of the vesicle is usually so short that the physician sees the patient after the vesicle has ruptured, and there is a red exuding surface. The exudation is sticky or gummy in character and stiffens the hair and linen.

In children and infants the inflammation is usually intense, and the skin is swollen and red. This is the infantile eczema rubrum of the textbooks.

Pustular eczema is this type when it has become infected by the pus organism; then instead of exuding clear serum, the discharge becomes purulent and dries into brownish, or greenish crusts; instead of the thin, yellowish, friable scales of a serous exudate.

Postular eczema is more frequently seen on the head and face of strumous and ill nourished children or those whose skin and clothing have not been kept clean. It is also the sequel of pediculosis capitis; then the eruption is found on the scalp, especially over the occipital region and the back of the neck.

Squamous eczema, eczema squamosum, may follow any of the other types, and as it indicates that the attack is declining, it might be termed the type of resolution.

The greater the amount of previous inflammation the greater and more persistent the scaling and vice versa.

*Etiology.*—It is difficult to discuss the etiology of eczema in infants and young children in a limited paper, for so many factors must be considered. The exact cause or causes are perhaps still obscure, but we do know that the great majority of cases seen in the very young are due either to external irritants or reflexes from the gastrointestinal tract.

Heredity plays but a small role in its causation. Children who have inherited delicate skins are especially subject to eczematous outbreaks, provided there is any irritation either external or constitutional. Males seem to be slightly more subject to eczema than females.

In the true definition of the term, eczema cannot be said to be contagious or parasitic, unless those cases of catarrhal dermatitis that are the sequel of ring worm or scabies are included under the head of eczema.

The diet has considerable influence in producing the disease in small children; over feeding has as great an ætiological bearing as the kind of food given.

A great deal has been said about the influence of dentition in the production of eczema; dentition is a physiological process and never causes eczema or any other skin disease; but reflexly, through digestive disturbances, it may cause an eruption on the face of children, the so called tooth rash, which can readily become eczematous. Intestinal parasites may cause an outbreak of eczema in children so predisposed either through reflex impression, or by their disturbing influence upon the digestive functions. A tight foreskin, or adhesions of the hood of the clitoris may produce a reflex eczema, but it should be remembered that every male infant who is the victim of eczema is not the possessor of a tight foreskin, nor does every child with a tight prepuce develop eczema. In short one thing alone, be it dentition, a tight prepuce, or a disturbed digestion, is not capable of producing an outbreak of eczema in young children; there are usually many factors that enter into the sum total of the ætiology of the disease.

*External Causes.*—Among the external causes of eczema should be mentioned the animal parasites (pediculi and the scabic louse) and diseased, or more properly speaking malformed skin, as illustrated by ichthyosis, over clothing and improperly placed clothes and binders, woolen underclothing, and sometimes, in older children, the presence of irritating dye stuffs in the clothing that comes in contact with the skin.

*Diagnosis.*—In infantile eczema, as in other diseases, the correct diagnosis must be made before the proper treatment can be instituted.

There are certain diseases that bear a transitory resemblance to eczema, and to distinguish them seems to be a difficult task to many practitioners. In making a diagnosis the physician should place before his mind the picture of a catarrh of the skin, with its attendant erythema, vesiculation, papulation, exudation, and crusting; the exudations being of a sticky, mucilagenous nature. If this picture is remembered, then the distinctive diagnosis and treatment become a comparatively easy matter.

The principal skin diseases which might occur in infants and young children, that could be mistaken for eczema are: Scabies, impetigo, erythema, and syphilis. The distribution of scabies is so pathognomic that even when aggravated by maltreatment and scratching it assumes an eczematous character it should be easily distinguished. It would seem that the eruption produced by head lice could be easily diagnosed and not mistaken for eczema; the characteristic location on the occipital region is enough to stamp it pediculosis and not eczema.

Impetigo. If the eruption is composed of closely aggregated pustules it might easily be mistaken for impetiginous eczema, providing the characteristic targets that impetigo always begins as observed pre-

sized blisters, containing serum, which soon become seropurulent, and not as pin point or pin head sized papules or vesicles, which exude a sticky, serous fluid. The impetiginous lesion dries into a brownish crust, while the eczematous vesicle generally ruptures spontaneously.

Erythema.—In infants and children this is easily distinguished from eczema, but if a mistake is made, the erythema can readily become a true catarrh of the skin.

The symptoms of inherited syphilis in infants are so well marked that, to an audience of this character, it is only necessary to mention it in passing.

The other diseases which are frequently mistaken for eczema are erysipelas, miliaria, dermatitis, herpetiformis, ring worm, and favus; time will not allow me to enter into their discussion.

The symptoms of eczema in young children are constipation or loose movements indicative of intestinal irritation, some febrile disturbances, restlessness caused by itching, and the acute or subacute eruption which assumes one or more of the types previously described.

*Treatment.*—The treatment of eczema in infants and young children must be divided into two parts: First, the care of the child; and second, the treatment of the disease proper. The first division is the more important, for if the child is properly and hygienically cared for the treatment and cure of the cutaneous disease proper is often an easy matter.

Clothing.—The clothing of the child should be as light as possible; heavy flannel underclothing should be avoided, in fact, many children have an inherited idiosyncrasy to woollens; in these cases all the clothing that comes in contact with the skin should be of either linen, cotton, or silk. Most mothers and nurses make the mistake of keeping the baby too thickly covered; the clothing and covering should be just sufficient to protect the child, and not great enough to stimulate the cutaneous glands.

Care should be taken not to have the binders or bands of the clothing too tight upon children with sensitive or tender skins.

It would, perhaps, be better for the cutaneous integrity of the infant if water for bathing could be avoided, and some bland oil, such as olive or almond, be substituted; but it is almost impossible to properly remove crusts, soiled secretions, and debris without water, yes even soap and water! The water should be soft, rain or spring water, but if this is unattainable, water that has been boiled and cooled will be found quite as good; bran baths to which a small quantity of sodium bicarbonate has been added will often be found useful; castile, or the superfatted soaps, can be used when soap is indicated, but it is better to use as little soap as possible, for even the mildest will irritate some skins. After the child has been thoroughly dried, the body, diseased portion and all, should be thoroughly innuncted with some bland grease, such as cold cream or almond oil. The physician should be careful to prescribe a perfectly fresh oil or the best cold cream, for it is a fact of common observation that much of the olive or almond oil procured from the drug store is apt to be rancid, and the cold cream so badly made that it acts injuriously on sensitive skins.

I think that dermatologists as well as pædiatrists make a mistake when they impress upon the minds of the mother or nurse the dangers of using water on an eczematous skin; proper bathing at stated intervals, every third day or once a week or longer as the case requires, is not only noninjurious but beneficial, for, as stated above, water is the best medium for removing soiled cutaneous secretions and other deleterious material. After the bath the child should be thoroughly innuncted with cold cream or dusted with some bland powder, preferably of mineral origin, because the vegetable, such as lycopodium, rice powder, or starch, take up the secretions, become rancid, and readily serve as culture mediums. Most mothers and nurses use talcum powder for dusting; the only objection to this is that it is apt to roll up in lumps; this can be prevented if the powder is thinly and evenly distributed. The oxide or stearate of zinc with or without bismuth is useful. A commercial powder called pulvula, which is said to be a zinc preparation, fills the requirements of a dusting powder better than those mentioned. Among the vegetable powders, lycopodium stands at the head, although in some cases either rye or buckwheat flour has a more soothing effect.

It seems needless to say that a child with eczema should be handled as little as possible, but it is a fact that is constantly disregarded by mothers and nurses.

Feeding.—The feeding of infants is a matter that tries the skill of the medical profession; and the difficulties are multiplied when the child is suffering from eczema.

It is a matter of common observation that the majority of eczematous children have been or are fed on artificial foods; these starch compounds have so upset the intestinal tract of the child that after repeated insults the skin becomes reflexly irritated, and eczema is the result.

The proper food for an infant, especially one with a sensitive skin showing a predisposition to eczema, is human milk. If this mode of feeding is impossible, cow's milk, either plain or properly modified, is the best substitute.

I have found that children fed upon sterilized or pasteurized milk are more subject to reflex eczemas from disordered digestive organs than those fed the plain or modified milk, and if pasteurized or sterilized milk is given to infants already suffering from eczema the disease is aggravated. The possible explanation of this is expressed by a remark of Jensen, quoted by Piffard in an article on milk in the *New York Medical Journal*, January 4, 1908. "The bacteria surviving pasteurization are, for the most part, the quick growing bacteria of putrefaction which are inhibited in raw milk by the lactic acid bacteria, but in pasteurized milk they multiply very fast, and undoubtedly they are capable of generating poisonous substances."

I have found the best modification of milk for children with eczema is the one formulated by Professor Bartley, and with his kind consent it is given in full:

"Strain off from the bottom of a bottle of fresh milk of good quality three fourths of its contents, leaving the cream and upper part of milk undisturbed in the bottle. This may be easily done with a piece of small rubber tubing, previ-

ously filled with water, to start the siphonage. Pinch one end of the rubber tube and hold it firmly, while the other is thrust through the cream and to the bottom of the bottle. Lower the outer end into the inner vessel of an ordinary double boiler, and release it when the skim milk will run out, provided the latter vessel is kept lower than the milk in the bottle. To the milk thus drawn off add a teaspoon and a half of Fairchild's essence of pepsin, or one junket tablet, and warm slowly in the double boiler to blood heat, or until the milk is well curdled. Now continue the heat with rapid stirring, until the thermometer indicates 150° F., when the curd should be well separated. Remove from the fire and strain, dissolve in the whey a heaping tablespoonful of sugar of milk. When cold pour the whey back into a milk bottle, and mix thoroughly with the top milk. In hot weather the mixture can be pasteurized, but it is not necessary in cold weather. If the food should prove too laxative reduce the quantity of milk sugar. It is well to add from one to two teaspoonfuls of lime water to each meal. As the child increases in age the amount of bottom milk siphoned off may be diminished.

After the child has cut its teeth milk should still constitute the bulk of its diet, with the addition of beef juice, cream, dry bread, and zwieback, and in the strumous cases benefit can be derived from the judicious administration of oils and fats; orange juice and baked apple can also be added to the dietary; it is often necessary to direct the mother to give the child frequent and liberal draughts of either soft or boiled water, this assists in the elimination of waste material.

**Constitutional Treatment.**—Most eczematous children are constipated; and various formulas have been devised for relief, but there can be no definite prescription given that will suit all cases. Occasionally a dose of castor oil is indicated; calomel in from one half to one grain doses either alone or combined with small quantities of rhubarb or castor oil will be found useful, this can be followed by magnesium milk or magnesium citrate; cascara sagrada in one of its various combinations is commonly employed by many physicians; while this drug is of undoubted benefit after awhile a tolerance is established and then recourse must be had to other remedies. Phenolphthalein, a recently advised preparation for the relief of constipation, is rather uncertain in its effects; in some instances a quarter of a grain dose will regulate the bowels, and again a much larger dose is necessary, while it often happens that even a small dose will cause intestinal discomfort and even pain.

I have found that malt sugar seems to work well in certain cases; this can be conveniently given in the shape of malted milk, one or two feedings in the twenty-four hours being sufficient to overcome and control the constipation. I know the use of malt sugar is against the teaching of pædiatrists, on the statement that sugar will cause fermentation and acid stools; while this may be theoretically true, I personally have never noticed any bad effects either upon the disease in question or upon the digestive functions of the child to whom it has been given.

No laxative should be given in large enough doses or for a sufficient length of time to cause purgation; the dose should be just large enough to relieve the constipation and regulate the bowels, except in those children that are heavy feeders and poor eliminators, then an initial dose of either calomel or castor oil can be prescribed to rapidly relieve and clean out the intestinal tract.

If the child is still at the breast some of its con-

stitutional treatment can be given through the mother. In the strumous eczema codliver oil and the iron iodide is indicated; if the eczema should be a manifestation of inherited syphilis, minute doses of calomel or bichloride of mercury will often effect a cure when other measures have failed. Calomel, or mercury and chalk in small doses is indicated for eczema in children of the flabby, lymphatic type.

The most troublesome symptom of eczema is pruritus; this can usually be relieved by external applications, if not, small doses of bromide or chloral can be given, but when these drugs are used their action should be closely watched, for the bromides are capable of causing a serious looking dermatitis, and when the skin is already diseased this drug should be most judiciously employed.

The routine administration of arsenic in infantile eczema should be most strongly condemned, for it does little or no good to the cutaneous disease and is apt to disturb the digestive processes; this drug is only indicated when its tonic effect is desired.

The important rule regarding internal medication is to give as little medicine as possible; for if the child is properly bathed, clothed, and fed, its constipation relieved, and the proper external application is used, little else will be required to effect a cure.

**External Treatment.**—The external treatment should be protective; the cardinal principle is not to apply anything to the skin that will irritate it, so, therefore, all ointments, lotions, or powders should be bland and protective.

All scales and crusts must be removed before any medicinal application is used; the scales can be softened with olive or almond oil, to which can be added one to three grains of resorcin or carbolic acid to the ounce. The oil can be used for a few days or until the scales are softened, then the parts should be thoroughly washed with soap and bran water, or water to which a small quantity of sodium bicarbonate has been added; the washing should be repeated as often as is necessary. During the interval between the water baths the parts can be cleansed with oil.

For the erythematous type, where there is little or no vesiculation, the application of some simple protective ointment, such as cold cream, petrolatum, or wool fat, will be all that is necessary; the petrolatum should be the refined white petrolatum, and it is not prescribed with an idea of a medicinal effect, but as a simple protective covering for the skin.

If the child is much exposed to the outer air it is sometimes advisable to cover the unguent with some bland dusting powder.

In eczema rubrum, if there is not much inflammation, benefit can be derived from dusting the diseased part with zinc oxide or bismuth, either separate or combined. If the diseased surface is much irritated and inflamed a mild boric acid lotion can be used until the inflammation subsides, and then an ointment composed of zinc oxide, ammoniated mercury, and cold cream will be found useful.

The physician is cautioned against prescribing the commercial zinc oxide ointment, as it is either too strong for the individual case, or the fatty base has become rancid. Cold cream is a much better oint-

ment base than benzoated lard. While it is not the purpose of the paper to give any prescription, the following combination will serve as an example of prescriptions when used—

- R. Ammoniated mercury, ..... 10 to 15 grains;  
Zinc oxide, ..... 10 to 25 grains;  
Cold cream, ..... 3j.  
M. S.: Externally.

If there is much pruritus carbolio acid or some tar preparation can be combined. If the disease has become chronic oil of cade or beta naphthol in from ten to thirty grains to the ounce of an ointment will assist the cure. In prescribing the tar preparations physicians should use discriminating judgment, for the tars do not act well in all cases; in fact, they frequently aggravate the existing inflammation, and sometimes produce a tar dermatitis. Occasionally cases of eczema resent any fatty applications, then lotions, such as the calamine lotion, must be resorted to.

The physician should examine the genitals, and if any adhesions are found they should be removed.

If the attack of the skin disease appears for the first time during the eruption of the teeth, or if the skin condition seems to be aggravated, appropriate measures should be instituted to assist dentition.

In concluding it is only necessary to reiterate what was said in the beginning, that it is extremely difficult to lay down any fixed rules for the treatment of eczema; for the remedies, be they internal or external, must meet the exigencies of the individual case and condition.

47 HALSEY STREET.

#### THE VALUE OF STAINED SMEARS IN THE DIAGNOSIS OF DIPHThERIA.\*

By E. BURVILL-HOLMES, M. D.,  
Philadelphia,

Formerly Assistant Chief Resident Physician of the Municipal Hospital; Bacteriologist of the Henry Phipps Institute.

I think that it is undoubtedly the opinion of men who are conversant with diphtheria, both in its clinical and bacteriological aspect, that in no case is the specific organism absent from the parts involved. True, there are a few men—fortunately, very few—who still have a tendency to deride or consider of little moment the findings of the bacteriologist, and who insist that mere inspection of the throat, etc., is sufficient for diagnosis, the aid of the microscope not being essential. These men either cannot or will not accept what are facts, not theories merely, and that is that organisms other than the Klebs-Loeffler bacillus can produce pseudomembranes identical with this later organism, and I think mainly because they know little about, and have worked less in, bacteriology. That this has been and can be proved beyond the peradventure of a doubt must be apparent to any one who has kept abreast of the literature or has made investigation for himself. Klebs (1) observed a whole family epidemic of false diphtheria which was caused by a large monococcus of the group of monads. Ballouche (2) has shown that typical diphtheritic pseudomembrane can be produced by the streptococcus, as also by the staphylo-

coccus and pneumococcus. Moreover, according to Bourges and Futterer, paralysis identical with that which often follows in the wake of a diphtheria intoxication has been seen as a sequelæ of a pure streptococcus angina. Again, Frankel's pneumobacillus can be responsible, and at times is, for errors of diagnosis. The symbiosis of Vincent's spirilla with the fusiform bacillus gives rise to an exudate, a pseudomembrane, call it what you will, which on more than one occasion, to my knowledge, has caused an individual unfortunately so afflicted to be sentenced to an enforced sojourn in a ward of the diphtheria pavilion. Another organism, which of late years we have been led to strongly believe is the ætiological factor of syphilis, the *Spirochæta pallida*, has been, while not to the same extent, guilty of the same thing. To quote from a report of the local Government Board of London (3), "It must be remembered that membranes produced by bacteria other than the Klebs-Loeffler bacillus may appear in the throat, and that in many cases the clinical phenomena prove it to be of little assistance; in these cases a careful bacteriological examination should always be made." Filatov (4) says: "In the diagnosis of the throat, clinicians are guided, not by the anatomical changes of the mucous membrane, but by the ætiological causes, namely, diphtheria of the throat is an inflammation of its mucous membrane produced by the Klebs-Loeffler bacillus. It is immaterial whether the throat be affected by a croupous exudation or a catarrhal one: as soon as we find that in a given case the cause of the sore throat is Loeffler's bacillus, we should regard such morbid process as diphtheritic and should so characterize it. Since not only Loeffler's bacillus is liable to produce diphtheritic inflammations of the mucous membranes, i. e., membranous exudations, but other microbes may also have similar action, it is obvious that the presence of a membranous coating alone on some of the mucous membranes does not prove that we have to deal in any given case with a case of diphtheria."

Personally I had the privilege and opportunity while at the Municipal Hospital of observing both clinically and bacteriologically many cases in which the inspection of the throat alone was responsible for errors in diagnosis, and I am certainly convinced that without a bacteriological examination one is not justified in saying that this case is one of diphtheria and that one is not. Let me here cite two cases as examples:

CASE I.—Miss C., a trained nurse, while caring for one of her associates who had been sent to the hospital suffering from scarlet fever, was taken ill with headache, rise of temperature, and angina. When her throat was first examined some slight whitish exudate was noticed on both tonsils, which later spread. It was considered a case of diphtheria and particularly in view of a report, by one of the resident physicians who, in my absence, examined a smear, that the Klebs-Loeffler bacillus was present in very large numbers. The patient was transferred to the diphtheria pavilion and antitoxine was administered. On my return to the hospital I was requested to examine the smear, and although it was carefully gone over not a single diphtheroid organism could be found. The first examiner had made the mistake, singularly so common with the inexperienced, of mistaking the *Streptococcus lanceolatus* with the diphtheria germ, this organism being in the smear exclusively, and substantiated by culture control. Although repeated cultures were made, the Klebs-Loeffler bacillus was never found. Twenty-four hours or thereabouts after-

ward the patient developed a cough with some dyspnoea, and while examination of her chest showed little or nothing, her subjective symptoms and her subsequent temperature reading made a diagnosis of central pneumonia more than probable. I may add that two days after the administration of the antitoxine she developed violent pains with swelling of her joints, and later a marked pericarditis with effusion. Whether the pneumococcus was responsible for the entire train of troubles, I am not prepared to say definitely. I believe that it was. A blood culture remained sterile.

Here then is a case where the pseudomembrane was indubitably pneumococcic in origin. It certainly was not diphtheritic, since as I say after repeated cultures the specific organism of that disease was never found.

CASE II.—W. J., a young male, was admitted to the diphtheria ward, suffering from malaise and angina. Examination of the throat showed a dirty white membrane on both tonsils and to a slight extent also on the uvula. Diagnosis other than diphtheria was not entertained at first, and he was, and properly, so treated. However, repeated negative cultures with the persistence of the membrane prompted the physician in charge to look further into the cause of the trouble and accordingly he was sent to the laboratory with a request that a smear be made and examined for the *Spirochaeta pallida*. This was done, that organism found, or what was thought to be the organism, appropriate treatment was adopted, and the exudate promptly disappeared.

And so case after case might be recorded if time and space permitted. To repeat, then, I say that every case of diphtheria, providing the throat be properly swabbed and cultured, the culture incubated at the proper temperature—an important factor—and examined by a competent bacteriologist, will invariably demonstrate the bacillus. Conversely, and I cannot do better than quote Professors Kathnack and Hardy (5): "From the investigations made all over the world, we must refuse to call any lesion diphtheria unless it is associated with the bacillus. The bacillus asserts itself with an authority which must put aside any preconceived notions." There are those, of course, who will argue that the bacteriological investigation in a given case is not necessary, because if so suspicious as to be distinguished with difficulty, it should be for the welfare of the patient, as also for those with whom he might come in contact, that the treatment and precautions against contagion should be in accord with the assumption. Conceded; until the diagnosis can be clinched, as it were, by the microscopist, all this should be done, and promptly. If, however, the subsequent treatment is to be carried along logical and scientific lines; if that chaos in households which a wholesale disinfection entails is to be eliminated; if the perturbed mind of a parent consequent upon the knowledge that her child has diphtheria is to be set at rest, and lastly, and by no means the least, if statistical records are to be open to less criticism than they unfortunately are at the present time, then it is essential that bacteriological studies should be made in every case of exudative angina. Again, the argument has been advanced that since diphtheria organisms are found in healthy throats, as are in many instances with measles and other viral infections, the detection of diphtheria, when, as a matter of fact, that organism may be taking little or no part in the diseased process. This leads us to the question as to how many well persons harbor the organisms in their throats. According to a report of a com-

tee of the Association of the Massachusetts Boards of Health (6) persons not exposed to the contagion revealed the germ on culture in 3 per cent. of cases. In the eastern part of the United States the percentage was lower, or 1.39 per cent. On the other hand, their report says that in the exposed the percentage was from 8 to 50. If this latter is correct, then my experience must be somewhat unique. Smears and cultures from the resident physicians and nurses on duty in the diphtheria wards were taken at the various periods, and of the eighty or ninety so studied, only two gave positive results, or 2.2 per cent. Both were nurses, and singularly newcomers, having been in the hospital but four days, one of whom went down with the disease the day following the issuance of the report. To obviate any prejudice in the matter the cultures were made by one of the resident physicians and sent to the laboratory with those from the patients and under fictitious names. At any rate, the number of well persons whose throats contain diphtheria organisms are so comparatively few that, when found in diseased throats, we are justified in the inference that the case is one of diphtheria.

*The Value of Smears.*—Early diagnosis of pseudomembranous anginas is imperative, firstly, so that prompt remedial measures can be instituted, and secondly, if contagious, immediate isolation or removal of the patient to the hospital effected. That diphtheritic anginas frequently present the typical textbook pictures of follicular tonsillitis is a recognized clinical experience of many practitioners. Indeed, more than one life has been sacrificed because the clinician failed to appreciate this fact. It is not so many years ago that in an orphan asylum on the outskirts of this city such an error cost the loss of five lives and the expenditure of about four thousand dollars. In the following cases the Klebs-Löffler bacillus was undoubtedly responsible for the trouble, although the clinical picture was that of follicular amygdalitis:

CASE III.—A girl of ten years was sent to the hospital from their suburban home, with a request that she be admitted, as she was supposed to be suffering from diphtheria. On admission inspection of her throat revealed two much enlarged and congested tonsils, each having thereon a small membranous patch of yellowish purulent exudate. Her condition was considered as being a case of tonsillitis and not diphtheria, and certainly the appearance of the parts justified such a diagnosis. However, before discharging her to her home, as it was the intention to do if the smear should prove negative, it was deemed advisable to make a smear from the exudate, which was done. This showed an exceedingly large number of diphtheria organisms, and the next day a pure culture of the bacilli. Furthermore, a

CASE IV.—E. K., a druggist, presented all the clinical features of diphtheria. The throat was examined and the tonsils were found to be enlarged and congested, and each had thereon a small membranous patch of yellowish purulent exudate. A smear from the exudate showed a large number of diphtheria organisms, and the next day a pure culture of the bacilli. Furthermore, a

CASE V.—J. A., a young man, presented the clinical features of diphtheria. The throat was examined and the tonsils were found to be enlarged and congested, and each had thereon a small membranous patch of yellowish purulent exudate. A smear from the exudate showed a large number of diphtheria organisms, and the next day a pure culture of the bacilli. Furthermore, a

his initial diagnosis. Only when it was too late did he realize what he had to deal with, and the child died.

The following case was one in which a diagnosis of diphtheria was made but which smear and culture proved undoubtedly to be staphylococcic infection:

CASE VI.—Miss H., a trained nurse, was sent from one of the local hospitals where she was on duty with a diagnosis of diphtheria. On one tonsil was a small, white patch of exudate, about five millimetres in diameter. The tonsils were not markedly congested or enlarged. There was slight dysphagia. A smear was made, but no diphtheria organisms were found after a long and careful search. She was immediately discharged, and the next day, without any treatment whatsoever, she was entirely well, at least to all intents and purposes. The culture made from the same swab from which the smear was made showed on the following day a pure culture of the *Staphylococcus pyogenes aureus*.

We see that in Cases III, V and VI where smears served a good purpose. Had inspection alone been relied upon, it is easy to see how disastrous might have been the results, and particularly as regards Case III, where the child would have been sent home, there to mingle with other children. To have awaited the results of culture would have meant detention in the hospital for at least seventeen hours. Removal of Case IV to the Municipal Hospital was consummated one hour after the visit of the physician, in lieu of being deferred twenty-four hours had culture alone been relied upon, thus obviating the dangers of contagion, as the patient was a resident in an apartment house. The smear saved Case VI from being subjected to antitoxine treatment and forced detention in the diphtheria pavilion unnecessarily. Had a culture or smear been made in the case of the small boy a life might have been saved.

Being desirous of ascertaining the value of smears compared with cultures made and examined, a considerable number of smears were made from the noses and throats of patients admitted to the diphtheria and scarlet fever wards. My conclusion is that they are of great value, indeed, in experienced hands as valuable as cultures, because even the latter, owing to careless culturing for the most part, do not always reveal the true state of affairs. Of special value are they when an immediate diagnosis is required. The experience of Welch and Schamberg (7), who examined a large number of smears also at the Municipal Hospital, is much in accord with my own. It would be a mistake for me, however, to leave the impression that it is easy to positively identify the organisms in smears without some experience, as is demonstrated by the smaller percentage of errors as this experience is augmented. Smears obtained from the nose in particular are oftentimes difficult to interpret. But then I do not believe that either smears or cultures are of much value in diagnosing nasal diphtheria without the clinical evidence or guinea pig tests, because the nose is a frequent habitat of an organism the morphology and cultural characteristics of which—to the exclusion, perhaps, that it renders bouillon slightly turbid—are identical with those of the Klebs-Loeffler bacillus. It does, however, lack virulence. From the nose, also, even in culture, I have observed that virulent organisms only rarely show polar staining or granules, as is so frequently seen in those from the throat. As a matter of fact

polar staining and granules are often absent in organisms from throats as examined by smear. The grouping of the bacillus, rather than their actual morphology, I consider the more valuable in recognizing their presence. In looking over a smear containing the bacillus, they will be found in most part lying together in groups of two or more, parallel to each other or radiating from each other like the spokes of a wheel. This is most characteristic both in smears and cultures.

Of 529 smears examined, only in thirty-one did they fail to correspond with the cultures, and in every instance the smear was made from the same swabbing as the culture. This is a difference of 5.8 per cent. In twelve of these cases the report on the smears was positive when the culture showed no diphtheria organisms, although the case was one of diphtheria, as subsequent cultures proved. In three instances I can account for this as owing to a gas regulator which refused to regulate, and being a warm night in summer the temperature of the incubator rose to 52° F., a degree of heat we know to be prejudicial to the growth of the Klebs-Loeffler bacillus. In the remaining cases the discrepancy was due to the fact that other organisms doubtless predominated and choked out the diphtheria bacillus. Whatever the reason, it showed that here at least the smears were more reliable than the cultures. This, then, leaves twenty-four cases in which the error was on the wrong side, or 4.1 per cent. Six of these, again, were from the nose, a site from which, as I remarked before, it is at times difficult to interpret. In two of these six cases a long search of the smear failed to show any organisms whatsoever, and quite recently I was asked to examine a nose smear from a young physician which showed, and then only after considerable hunting, a single pair of organisms, lying side by side, on which finding he was isolated and later sent to the Municipal Hospital. The culture made from this latter patient showed the organism solely. Withal then, with these results—because even cultures, depending upon personal equation, incubator troubles, or the choking out of the diphtheria bacilli by more rapidly growing organisms, will show a degree of error of at least 4 per cent.—I do not think it is without the pale of consistency to give a value for smears almost as great, if not as great, as cultures. I would suggest, nevertheless, that cultures as controls ought always to be made, and it would be time well spent if every young clinician would make himself conversant with this means of diagnosis.

#### Conclusions.

No pseudomembranous angina should be considered as one of diphtheria if, after careful and proper culturing and competent examination, the Klebs-Loeffler is absent.

Cultures and smears should be made in every case irrespective of the appearance of the parts involved.

Typical pictures of follicular amygdalitis frequently show large numbers of virulent bacilli.

When in doubt, and until smear and culture can be examined, all cases should be treated as diphtheritic in origin.

That without clinical evidence or guinea pig tests, smears and cultures from noses are not of much value.

The grouping of the bacilli, rather than the

morphology, is the more valuable aid in the identification of the bacillus in both smear and culture. For immediate diagnosis smears are of great value; indeed, from the results obtained in the cases mentioned, it would tend to show that on the whole they were as valuable.

## SYMPTOMATOLOGY AND DIAGNOSIS OF NEPHRITIS.\*

By DOUGLAS VANDERHOOF, A. M., M. D.,  
Richmond, Va.,

Adjunct in Medicine, Medical College of Virginia

More than one hundred years ago Nicholas Cotingo discovered a coagulable substance in the urine of persons afflicted with dropsy. To Richard Bright (1827), however, is due the credit of having produced the first evidence of the association of dropsy as a symptom, albuminuria as a sign, and altered kidney structure as a cause. Any one who has had the good fortune to have examined a copy of Bright's original monograph cannot fail to be impressed by his remarkable appreciation of the relationship of diseased kidneys to albuminuria and the clinical features of the affection which now bears his name. Equally wonderful are the beautiful colored plates illustrating lesions of the kidneys as he saw them at the post mortem table. Since Bright's time a certain knowledge of organic and functional disturbances of the kidney has been acquired, but were he to return to-day he would find us deeply perplexed over many of the same problems that confronted him.

It is generally conceded that the term "nephritis" includes certain diseases of the kidney associated with, or dependent upon, an altered state of metabolism and a defective condition of the blood, so that the disease is always bilateral. It is characterized by inflammatory changes in the various tissue elements which do not, however, lead to suppuration; and is manifested clinically by various features in which albuminuria, dropsy, and cardiovascular changes are prominent.

A satisfactory classification of nephritis to include the different clinical forms as well as the various pathological pictures of the disease has never been made. The subdivisions proposed by Senator, however, offer a working basis for both clinicians and pathologists.

1. *Acute nephritis*. (a) parenchymatous; (b) diffuse.

2. *Chronic diffuse nephritis, without induration* ("chronic parenchymatous nephritis").

3. *Chronic indurative nephritis*: (a) secondary induration (secondary contracted kidney); (b) primary indurative ("chronic interstitial") nephritis; (c) arteriosclerotic induration.

### 1. *Acute Nephritis.*

Acute nephritis is a simple inflammation which may only involve the parenchyma, or functional elements, of the kidney (tubular and glomerular epithelium); or it may be diffuse, so as to involve the interstitial as well as the parenchymatous tissues.

#### a. *Acute Parenchymatous Nephritis.*

*Symptomatology.*—This form of nephritis not infrequently exists without any distinctive clinical manifestations, either in the urine or elsewhere, as has been so graphically demonstrated by Cabot (R. C. Cabot, *Clinical Examination of the Urine*, *Journal of the American Medical Association*, March 18 and 25, 1905).

In many instances only the epithelium of the tubules is affected, while the glomeruli are not involved to any extent. In the mildest cases the only lesion found is a cloudy swelling and degeneration of the epithelium, such as is common in the infectious diseases accompanied by "febrile albuminuria." The urine contains only a small amount of albumin, and usually presents the characteristics of "fever urine," is scanty in amount, deep amber in color, strongly acid in reaction, of high specific gravity, with little or no sediment, in which only an occasional tube cast is found. This usual textbook picture of the urine in febrile conditions is not seen so commonly now as heretofore, however, because of the hydrotherapeutic measures with increased fluid intake that are instituted in our treatment of fevers at the present day. Dropsy and uræmic symptoms do not occur, and the only subjective symptoms are those due to the primary intoxication or infection. The albuminuria usually disappears with the subsidence of the fever.

#### b. *Acute Diffuse Nephritis.*

In acute diffuse nephritis the changes in the tubules are accompanied or followed by changes in the glomeruli and interstitial tissue which are more frankly inflammatory in character, and symptoms of renal insufficiency appear that are wanting in acute parenchymatous nephritis. Acute diffuse nephritis is seen most commonly during or following infectious fevers, especially scarlet fever, after the ingestion of soluble poisons such as corrosive mercuric chloride, etc. It is the usual form of nephritis which characterizes the "kidney of pregnancy." Sometimes, particularly in those cases following exposure to cold, acute diffuse nephritis may rank as a distinct clinical entity, having the character of an acute infectious disease, with the only symptoms referable to the kidneys.

*Symptomatology.*—The onset is often abrupt, but may be gradual when the kidney lesion develops during the course of an acute infectious disease.

The most prominent symptom is dropsy, which is often the earliest evidence of the renal condition. Its appearance is usually coincident with the alterations in the urinary secretion. The œdema first appears about the eyes and ankles, but may rapidly progress

\*Read at a session on Nephritis, at the Pacific Scientific Meeting of the Southwest American Medical Society, held at Richmond, Va., January 16 and 17, 1907.

to a condition of general anasarca, associated with effusion into the various serous cavities of the body. In severe cases, particularly in children and in pregnant women, the first symptom may be a uræmic convulsion.

With the exception of dropsy, no other symptom is constant or characteristic in acute diffuse nephritis. Very often a pronounced anæmia develops quickly, with the low color index of a typical secondary anæmia. General constitutional symptoms are more or less marked. The patient looks ill, is often apathetic, if not somnolent. Fever, associated with a polynuclear leucocytosis, is often present.

The condition of the cardiovascular apparatus varies. In many cases the pulse tension is much increased, and, according to observations reported by Riegel, the rise in blood pressure in acute nephritis occurs early. This may be followed by a distinct hypertrophy of the left ventricle as shown by the increased area of cardiac dullness to the left and the accentuated second aortic sound. In other cases, especially severe ones, in which the strength of the myocardium is impaired by the toxic agent, the right ventricle becomes dilated, and the blood pressure may not be increased. This may be a factor in the occasional occurrence of acute cardiac dilatation. Pulmonary œdema may follow upon a gradual cardiac insufficiency or may be associated with a rapid effusion of fluid into the pleural sacs. As has been well said, the only vessels which do not leak are those of the skin, kidneys, and the intestines. The skin is dry and harsh, the urine scanty or suppressed, and the bowels constipated.

Gastrointestinal disturbances are inconstant, but the occurrence of nausea and vomiting always makes one apprehensive of approaching uræmia. Visual disturbances and retinal hæmorrhage may appear with the development of uræmia, but are rare as compared with their frequent occurrence in chronic nephritis.

*The urine* in acute nephritis is characterized by a diminution in the amount of the twenty-four hour secretion, the presence of albumin and tube casts, and usually red blood cells. But this usual urinary picture does not invariably obtain, however, as is well shown by the statistical reports of Emerson (C. P. Emerson, Cylindruria, *Journal of the American Medical Association*, January 6 and 13, 1906) and Cabot (*loc. cit.*).

The scanty urinary flow is sometimes the first symptom that attracts attention, and this is often coincident with the appearance of dropsy. In severe cases anuria may occur at the beginning. The total amount in twenty-four hours is commonly less than 500 c.c. and the specific gravity is normal or distinctly high. Albumin is almost constantly found, occasionally only in traces, but often in larger amounts, although it rarely exceeds 1 per cent. Tube casts are practically always present, and may be of any form, including epithelial, blood, and leucocyte casts. The urine occasionally contains much blood, and some red blood cells are almost constantly found on microscopical examination. The solids of the urine, particularly sodium chloride and phosphoric acid, are reduced, and the nitrogen excretion is said to be diminished.

*Diagnosis.*—The existence of an acute nephritis

can be positively affirmed in only a certain proportion of cases. When this renal condition is dependent upon an already existing acute infectious disease the symptoms of this complication may be entirely masked by those of the primary condition, especially if dropsy is absent. The urine will show the presence of albumin, it is true, but unfortunately this does not prove that morphological changes have taken place in the kidneys. If, in addition to the albumin, the urine (catheterized in females) contains more than the occasional epithelial cell, and a moderate number of red blood cells and leucocytes, additional data are present on which to base the diagnosis of nephritis. The occurrence of even slight œdema about the eyes and ankles is strong corroborative evidence.

In some cases the diagnosis is only too apparent. Other causes of albuminuria or of dropsy have to be excluded, however, such as chronic passive congestion of the kidney, amyloid disease, cachexia, and anæmia. A considerable degree of œdema of the ankles is very commonly noted when a patient who has been bedridden for several weeks, as with typhoid fever, first begins to walk. This is generally referable to the weakened state of the cardiovascular apparatus, and is only of a few days' duration.

The question whether the symptoms are due to an acute nephritis or to an acute exacerbation of a chronic kidney lesion is not always easy of solution. The clinical history may offer the most valuable data, while the absence of marked cardiovascular changes, together with normal eye grounds, speak for an acute process.

A difficult problem is presented in many cases of hæmaturia. Aside from such conditions as calculus, neoplasm, and tuberculosis of the urinary tract, and malaria, blood in the urine may be present in acute and chronic nephritis—so called hæmorrhagic nephritis—or occur idiopathically as an acute renal hæmorrhage—renal epistaxis. The diagnosis of nephritis cannot be made from the examination of the urine, as the presence of the blood not only makes the urine albuminous, but also causes any casts that may have been present to disintegrate because the specimen becomes alkaline so rapidly. The diagnosis will rest on the history, symptoms and the physical examination of the patient—dropsy, fever, changes in the heart and bloodvessels and eye grounds, and uræmic symptoms. Renal hæmorrhage is very apt to be intermittent, so that a bloody urine may alternate with one entirely free from blood and albumin. Very often the diagnosis cannot be reached until a specimen entirely free from blood cells is obtained, when chemical and microscopical examination will tend to show whether we are dealing with a normal secretion, or one from a pair of diseased kidneys.

The distinction between acute parenchymatous and acute diffuse nephritis is not easy. In typical cases the former condition is characterized by absence of œdema and a smaller percentage of albumin in the urine, while dropsy and more or less marked albuminuria indicate the more severe diffuse process. If albumin persists after the fever becomes normal we cannot be said to be dealing with a simple case of febrile albuminuria, and such an occurrence may be our only criterion of more or less extensive damage to the kidneys.

## 2. Chronic Diffuse Nephritis, without Induration.

Chronic diffuse nephritis was at one time considered to be the "second stage of Bright's disease" and so to form a connecting link between acute nephritis and the chronic indurative forms of the disease. While the careful study of the ætiological factors, course, and termination has shown that the different varieties of nephritis cannot be so arranged, yet in many respects, both clinical and pathological, chronic diffuse nephritis does occupy a position intermediary between the acute and chronic indurative types of nephritis.

**Symptomatology.**—The onset of chronic diffuse, or parenchymatous, nephritis is always insidious. While the one dominant symptom of this lesion, as in acute diffuse nephritis, is dropsy, yet prior to its appearance the patient usually suffers from a train of indefinite symptoms such as frequent headache, vertigo or "blind staggers," persistent gastrointestinal disturbances which do not yield to appropriate medication, a gradually increasing anæmia which is more or less uninfluenced by iron and arsenic, or recurring attacks of bronchitis. Not infrequently the lesion is discovered when the individual applies for life insurance, and in many cases only a general feeling of ill health associated with weakness and slight shortness of breath, causes the sufferer to consult a physician.

In a well developed case the appearance of the patient is most typical. The more or less widely spread œdema, the striking pallor, the mental hebetude, and the dyspnoea on slight exertion combine to form a clinical picture that suggests the disease at a glance. Other symptoms are inconstant and not at all characteristic. The heart is often enlarged, but here the factor of dilatation is of about equal importance with that of hypertrophy, and this so called eccentric hypertrophy differs from that form which occurs in indurative nephritis. The pulse is not characteristic, as it may be rapid and weak at the height of the disease when œdema is marked, while in other cases the tension is distinctly increased, which leads us to suspect that indurative lesions are developing in the kidney. Digestive disturbances are often the most distressing symptom early in the disease and quite apart from uræmic conditions, being dependent in all probability on an œdematous infiltration of the gastric and intestinal mucous membranes. Diarrhoea is not uncommon. Albuminuritic retinitis and cerebral hæmorrhage do not occur early in the disease, but are not so infrequent toward the end. At any time œdema of the brain or meninges may occur and give rise to many of the symptoms of uræmia. A papilitis, which may be confined to one eye, occasionally develops, or a condition of so called congestive neuritis and dropsy of the optic sheaths. In typical cases of chronic parenchymatous nephritis acute uræmic symptoms are not prominent except at the terminal stage of the disease. A certain number of the symptoms of chronic uræmia (see below), however, are as common as in chronic interstitial nephritis.

The urine is generally diminished in amount, although not necessarily so, as an increased secretion may accompany the rapid disappearance of dropsical effusions, or develop gradually coincident with indurative changes in the kidney structure. The specific

gravity, while usually high, varies with the daily quantity of urine excreted. The urine becomes ammoniacal very quickly on standing owing to the ready decomposition of its increased albumin content. Albumin is a constituent that is rarely absent in this form of nephritis. Except in those cases in which the lesion approaches the indurative type, the quantity of albumin is large, often ranging from 0.5 to 1 per cent. The sediment shows about the same constituents as in acute nephritis, but red blood cells are not so numerous unless there is a special tendency to hæmorrhage, or an acute exacerbation occurs. Casts are usually abundant, especially the coarsely granular, waxy, and fatty casts, but the urine must be examined promptly on voiding, as the casts go to pieces quickly in an alkaline urine.

**Diagnosis.**—In the majority of instances chronic diffuse nephritis cannot fail to be recognized, and, as Cabot says, the success in the diagnosis of this type of case is in striking contrast with the large percentage of failures in other forms. He further calls attention to the fact that the diagnosis may depend as much on the clinical features as on the urinary examination. From acute diffuse nephritis it is distinguished chiefly by the history of onset and clinical course, as well as by other points mentioned in discussing that lesion. Amyloid disease of the kidney may be very difficult to distinguish from chronic parenchymatous nephritis, and in some cases this cannot be done. The absence of causes which usually lead to amyloid degeneration is against the assumption of that disease. An acute exacerbation of a chronic interstitial nephritis may simulate a case of the parenchymatous form very closely, and only the history of the case, or possibly the cardiovascular condition, or often the subsequent course, may allow us to speak with any degree of assurance on this point. Chronic passive congestion of the kidney due to cardiac insufficiency, emphysema, etc., can usually be distinguished by discovering a cause for the congestion, but not infrequently we have equally good reasons to suppose that the heart condition may be of the nature of a relative insufficiency secondary to the kidney lesion. In such a dilemma we have to be satisfied with the diagnosis of a "cardiorenal" case.

## 3. Chronic Indurative Nephritis.

"Diffuse indurative nephritis may develop either primarily as the product of a protracted, or oft repeated, extremely insidious inflammatory irritation, or it may follow acute, subacute, or subchronic so called parenchymatous inflammatory states and represent their terminal stage—i. e., as so called secondary induration or contracted kidney. The primary form again may be either the result of some irritant acting directly on the renal parenchyma on account of some abnormality in the blood, or indirectly through the mediation of arteriosclerosis. The former is designated 'genuine (primary) renal cirrhosis' or simply 'chronic interstitial nephritis'; the latter is known as 'arteriosclerotic contracted kidney' or 'sclerosis of the kidney'." (Senator.)

**Symptomatology.**—The onset of chronic indurative nephritis is always gradual, except in the small proportion of cases that are secondary to acute nephritis. The patient experiences difficulty in describing either the time or the nature of the earliest

symptoms that may be attributed to the altered kidney function. I am in the habit of asking them when they were last perfectly well, but the information so obtained does not really give the exact duration of the process for the reason that the earliest evidence of the disease may be found in the urine for a certain period of time before symptoms manifest themselves.

As has been well demonstrated, there are two stages in the development of primary chronic indurative nephritis; the first, aside from certain variable and inconstant symptoms, is characterized only by changes in the urine, while the second has to do with the more characteristic clinical symptoms, chiefly referable to the vascular and nervous systems.

In arteriosclerotic indurative nephritis symptoms on the part of the cardiovascular apparatus are the first to appear, and definitely precede the changes in the kidneys and the appearance of abnormal constituents in the urine. So here, also, two stages may be distinguished, occurring in reverse order to those of primary indurative nephritis. While this arrangement of the symptoms is convenient for purposes of clinical or pathological distinction, yet it must be remembered that it applies only to typical examples of the two processes, and that many transitional or intermediary forms occur.

The changes in the heart and bloodvessels are in many respects the most important, both from the standpoint of diagnosis and prognosis. It is this very fact that makes the examination of the eye grounds of such great value, for in many cases the actual condition of the vascular apparatus is depicted more clearly by the ophthalmoscope than by any other available means of examination. In a clinically doubtful case I know of no greater comfort than the absolutely negative opinion of a competent eye specialist, while I certainly would hesitate to give anything but a most generally worded prognosis in the chronic disease of interstitial nephritis without the ophthalmoscopic report before me.

The ordinary subjective symptoms on the part of the cardiovascular system are dyspnoea, palpitation, and general precordial distress, vertigo, tinnitus aurium, and interference with vision. The objective features are hypertrophy of the heart, increased pulse tension, and hæmorrhage.

The frequent occurrence of cardiac hypertrophy, without valvular lesions, in chronic nephritis was first insisted on by Richard Bright, although his views were much contested until put on a firm basis in the classic treatise by Traube, in 1856. It is now a well established fact that the enlargement of the heart does not appear until after the urinary changes, particularly polyuria and albuminuria, have already existed for some length of time; and, furthermore, that the hypertrophy exists for some time without dilatation, and that it affects the left ventricle primarily and exclusively, or, at least, more than any other chamber.

The rise in blood pressure, which has now become of such importance in the diagnosis that progressive insurance companies have seen fit to include the manometric readings in the examination of all risks over forty years of age, apparently develops *pari passu* with the hypertrophy of the heart. The at-

tempts to explain the real cause of the increased pulse tension and cardiac hypertrophy have led to the promulgation of a great number of theories. While this problem still remains unsolved, yet it may be said, in short, that the various theories based on physical considerations are not tenable in view of the experimental studies on animals, and that the remaining theories either rest upon the assumption of unproved physiological factors, or an altered state of the blood which acts as an irritant to the vascular endothelium. Senator concludes that in primary chronic interstitial nephritis, owing to the insidious onset and slow course, the irritation of the vascular apparatus is no doubt more feeble than in parenchymatous nephritis. Accordingly the injury to the vessels in interstitial nephritis is not, as in the parenchymatous form of the disease, severe enough to allow the transudation of serum and dropsy; but that the persistent irritation eventually results in contraction of the vessels. The result is increased pressure in the whole aortic system and hypertrophy of the left ventricle. Further discussion of this phase of the subject will only lead us to theorize as to the yet unknown cause of nephritis in general, and serve to bring up the question as to whether the source of this supposed irritant is in the kidney, liver, or other organ of the body.

A very important group of symptoms referable to the vascular system is due to hæmorrhage. Cerebral hæmorrhage is, of course, the most serious form, and statistics show that it occurs in from 6 to 18 per cent. of cases. Retinal hæmorrhage is probably the most common lesion that we can demonstrate, and is therefore of special significance in diagnosis. Hæmorrhage from the kidney may be a feature of some cases of chronic interstitial nephritis. Epistaxis is not very uncommon. Rarer forms of hæmorrhage are metrorrhagia, hæmatemesis, hæmoptysis, and hæmorrhage into the intestine, tympanic cavity, pharyngeal and laryngeal mucous membranes, hæmorrhages into the skin, and lastly a condition of hæmorrhagic diathesis. These vascular features of nephritis are well set forth in a valuable paper by Riesman (David Riesman, Hæmorrhages in the Course of Bright's Disease, etc., *American Journal of the Medical Sciences*, November, 1907, page 709).

Symptoms on the part of the digestive system are not prominent in chronic nephritis except when due to passive congestion of the intestinal tract, or when associated with uræmia. The same may be said for the respiratory apparatus, except that patients are often subject to catarrhal inflammations of the upper air passages, or attacks of "renal" asthma, and that, with the general lowered resistance, the terminal event in chronic nephritis is not infrequently a pneumonia. When cardiac insufficiency develops there is passive congestion in the lesser circulation, with all its attendant symptoms.

Subjective symptoms referable to the nervous system are very common, such as headache, insomnia, neuralgia, retinitis, and papillitis, etc. Some of these symptoms assume special importance in regard to their relation to uræmia (see below).

The organs of locomotion, the skin, and the genital organs show no noteworthy changes that are not due either to hæmorrhage or uræmia.

The general state of the health may remain fair-

ly good for some length of time, and no pronounced alterations in metabolism are noted early in the disease. With the advent of chronic passive congestion of the intestinal tract, and in chronic uræmia, malnutrition becomes manifest and results in distinct loss in weight and strength and of the general resistance of the organism to various acute infections. The blood shows no important changes that are at all constant or characteristic.

The urine in chronic indurative nephritis, in the great majority of cases, shows characteristic changes which may be readily explained. The first change is the appearance of small quantities of albumin. This albuminuria for some length of time is distinctly intermittent, and the albumin may be entirely absent in the urine voided in the morning after a night's rest, but be found in a specimen passed in the evening after the ordinary physical exertions of a day's routine. This slight and distinctly periodic excretion of albumin later becomes more persistent, although it is never large in amount. More or less coincident with the albuminuria hyaline casts begin to appear, but they are often scanty in number and difficult to find. This intermittent albuminuria and cylindruria may occur for months, or even years, before subjective symptoms are noted. The first of these is a slowly developing polyuria, which gradually becomes more marked until the patient has his attention directed to the increased frequency of micturition, which is especially conspicuous when he finds that he is compelled to get up once or twice during the night to empty the bladder. When the nephritis is well developed the daily secretion of urine amounts to two to four litres or even more. The urine is pale, clear, definitely acid, with a constantly low specific gravity varying from 1.005 to 1.010, the albumin is seldom more than a distinct trace—0.05 per cent.—and casts are few.

The urinary changes in arteriosclerotic indurative nephritis differ from those in the primary interstitial form in that the polyuria is the earliest change, and an increased secretion of urine having a low specific gravity is the most constant sign of this disease. Albumin and casts may never be found until the kidney lesion, as well as the clinical symptoms, become marked. In other instances a slight trace of albumin may be found in the evening urine, and only prolonged search will reveal one or two hyaline casts.

At any time during the course of a chronic nephritis an acute exacerbation may occur with corresponding changes in the urinary findings. Also, when the heart begins to fail, the broken compensation gives rise to chronic passive congestion of the kidneys and other viscera, and distinct deviation from the usual urinary picture is found. Particular attention has been directed to these anomalous urines, because very often the patient only consults a physician when an acute exacerbation has caused the appearance of slight dropsy, or the failing heart brings about an unusual degree of dyspnoea. It is only after these transitory conditions have cleared up that the typical urinary findings reappear.

Other qualitative or quantitative changes in the urine are either inconstant or not necessarily characteristic of chronic indurative nephritis. The ques-

tion of the urea excretion shall be referred to in discussing the diagnosis of this affection.

The reasons for the changed character of the urinary secretion can be understood when the anatomical and physiological alterations in the kidney, heart, and bloodvessels are considered. It is a well accepted fact that the kidneys are, generally speaking, the first to suffer from any injurious substance circulating in the blood. Now, the action of the irritant, which is supposed to be the underlying cause of nephritis in general, first manifests itself in slight damage to the parenchyma, or secreting portions, of the kidney, and this accounts for the early albuminuria and cylindruria. The further action of this irritant, as has been already pointed out, brings about a general rise of blood pressure in the systemic circulation accompanied by hypertrophy of the heart. It is then quite conceivable that the increased pressure and velocity of the blood flow through the kidneys may be the cause of the increased urinary secretion, particularly water, characteristic of chronic indurative nephritis.

*Chronic Uræmia.*—The careful examination of the cardiovascular system and of the urine usually suffices to establish the diagnosis of chronic indurative nephritis. In spite of this it may be safely stated that a large proportion of cases are not diagnosed, and this is often due, I believe, to the failure on the part of the physician to fully appreciate the various symptoms that are due to chronic uræmia, so that he does not have his attention directed to the renal insufficiency as the cause of the patient's ill health.

Chronic uræmia is a toxæmia which occurs to a greater or less extent in all cases of chronic nephritis and with a symptom complex of considerable diversity. Most of the disturbances to which it gives rise are on the part of the nervous and digestive systems.

The motor symptoms, convulsions, etc., which are so prominent in acute uræmia, are replaced to a certain extent by psychic manifestations in this chronic toxæmia. The patients are for the most part apathetic, and frequently somnolent. Restful sleep, however, is not assured to these sufferers, and pronounced insomnia is a feature of some cases. Some patients, who have believed themselves perfectly well, may suddenly lapse into a condition of mental confusion, so that they experience difficulty in remembering their names or recognizing familiar faces. I saw such a case not long ago in a man of fifty-six, who was suddenly seized with severe gastric symptoms, to be followed by the mental condition just described; his blood pressure was 210 mm., and the ophthalmoscope revealed a unilateral papillitis. His symptoms slowly cleared up in about two weeks' time. In other cases distinct mental symptoms develop, such as profound melancholia, or mental depression, with delusions of persecution.

Headache, recurring and persistent, is undoubtedly the commonest symptom of chronic uræmia. It is an early feature, and may continue, with short periods of freedom, for many months. While it is frequently occipital, yet it varies in different cases, and also in the same one from time to time. A patient under my care at present describes his pain.

which is limited to the vertex, as if an object the size of a lead pencil were boring into one particular spot. This same patient complains of attacks of sharp pain in the "bones" of the arm and leg, about three inches above the wrist and ankle, which are severe enough to wake him up at night. Headache is often so predominating a symptom that patients state that they would feel perfectly well if they could only be relieved of it. This symptom is of special importance when it develops in an individual who has not been subject to headache.

Tonic contractions of different groups of muscles are prominent in some cases. Most commonly one sees cramps in the calves of the leg, especially at night, but a not infrequent symptom in some cases is severe and recurring abdominal colic. In one interesting case of mine this symptom caused the patient, a day laborer, to stop work and seek medical advice. During the four months he has been under treatment directed to the renal insufficiency this symptom has entirely gone, and he has insisted on resuming his usual occupation.

Among the eye symptoms of chronic uræmia myosis is commonly observed, although in acute uræmia the pupils are usually dilated. Retinitis is a relative common finding, and in some cases is associated with an optic neuritis, but many of these changes may be partly attributed to lesions of the bloodvessels of the fundus. Sudden and transient amaurosis may occur without visible changes in the nerve.

Disturbances in the sense of hearing are rather rare, except tinnitus, which is probably vascular rather than uræmic in nature. Vertigo, however, is a frequent complaint, and may be due to disturbances in the inner ear.

Other nervous phenomena consist of various forms of palsies which are associated with the uræmic state, but their character points to a focal brain lesion. In view of their transitory nature, they are probably due to œdema of the brain rather than either uræmia or hæmorrhage. These palsies include strabismus, monoplegia, and hemiplegia, paralyzes of the bulbar type associated with difficulty in speech and in mastication, etc. Numbness and tingling in the extremities is sometimes observed.

Chronic uræmia very frequently manifests itself in disturbances of the gastrointestinal tract. Distinct indigestion is an early sign, and probably ranks only second to headache as an important symptom of renal insufficiency. Loss of appetite is a feature of some cases of chronic nephritis, and the patients usually state that the slightest indiscretion in diet upsets the stomach very promptly and often induces nausea and vomiting. These early gastric symptoms, like the headaches, are usually periodic, as on some days the food is relished and retained without difficulty, while at other times the patient has absolutely no desire for food, and attempts to eat bring on nausea and vomiting. The tongue is often heavily coated, and much complaint is made of the foul taste in the mouth. Such symptoms as these occurring in persons of the age at which chronic interstitial nephritis is common should always direct attention toward this lesion, and the presence of in-

creased pulse tension, accentuated second aortic sound, and the history of increased frequency of urination make the diagnosis very probable even before the urine is examined. I remember just such a case as I have described which I saw last summer in a woman, sixty years old, who had been under the successive care of three physicians, and had probably been given digestive mixtures *ad nauseam* (literally). Under appropriate medication directed to the kidney condition her improvement was most prompt and striking, and when I last heard of her she considered herself practically well. I have a patient in the hospital at present with well marked interstitial nephritis. He is unable to definitely fix the onset of his ill health, but it is very instructive to note that he consulted a physician in the spring of 1906 for "stomach trouble," and that he was referred to a specialist for a gastric analysis, etc. The bowels are regularly constipated, and this is often so marked that one of my former teachers used to declare that a patient will not die of uræmia as long as one can keep his bowels open. It is said, however, that severe diarrhœa may be a feature of uræmia, but I rather believe that this occurrence is of the nature of a terminal infection of the bowel, as the dysenteric symptoms may be marked, and on post mortem are often found to be associated with ulcerative processes in the intestines.

Respiratory disturbances dependent on uræmia are rare, as they are due to the associated cardiac insufficiency and consequent passive congestion in the lesser circulation. The occurrence of Cheyne-Stokes respiration is likewise due to insufficient aeration of the blood and its direct effect on the respiratory centres.

The skin is usually dry, but this does not indicate that the patients cannot be made to sweat profusely. Intolerable itching is said to be a frequent symptom, which is sometimes attributed to overloading of the blood with urinary constituents, so that the sensory nerves are irritated. I have failed to observe this symptom in chronic nephritis, except in patients who were receiving morphine.

*Diagnosis.*—There are three essential points to be considered in the recognition of chronic indurative nephritis: First, the physical examination of the patient, with special regard for the condition of the cardiovascular apparatus; second, the examination of the urine, bearing in mind the apparently slight variations from normal early in the disease, or even after it is well established; and, lastly, the full appreciation of the significance of the symptoms that may characterize the condition of chronic uræmia.

The cardiovascular features of chronic interstitial nephritis, while not the earliest signs of the disease, are, nevertheless, prominent and important from the diagnostic standpoint. Increased pulse tension is usually indicative of a kidney lesion, though not necessarily so. Even in the absence of dyspnoea the tongue often shows a distinct cyanotic tint, and the second heart sound over the aortic area is found to have a sharp, ringing, accentuated tone. The apex beat is displaced downward and to the left, and is strong and heaving. If any degree of dilatation

has occurred the relative insufficiency of the mitral valve is denoted by a systolic bruit over the mitral area. The condition of the radial and temporal arteries may suggest the arteriosclerotic basis for the nephritis.

The ophthalmoscope may reveal most important evidence in the diagnosis of nephritis, and the large number of cases that are first recognized by the eye specialist will always stand to the general practitioner's discredit. Chronic nephritis should certainly be diagnosed before retinal hemorrhage has occurred, although in some few cases interference with vision may be the symptom that first seriously affects the patient, so that he consults an oculist rather than his family doctor. In any doubtful case the eye picture may settle the question, and it would be well for every medical man to be sufficiently versed in the use of the ophthalmoscope so that he can recognize the grosser retinal lesions. The instrument that is equipped with an electric incandescent light is a most convenient one to use, as it requires very little dexterity in its handling, and the patient can be examined while lying flat in bed in a room not necessarily darkened. Slight degrees of neuroretinitis are, of course, more safely left to the judgment of the specialist. As I have stated before, I regard the retinal changes as being of special value not only in the recognition of the disease, but also in enabling us to give a more definite prognosis in many cases.

The most important features of the urine in chronic indurative nephritis are the total amount in twenty-four hours, the specific gravity, and the presence of a small amount of albumin and a few tube casts. Are we justified, however, in making a positive diagnosis in view of such findings? Most certainly not. Urines presenting just such characteristics may occur in other conditions, and it should be emphasized that the urinary examination is only of value when considered with the clinical history and physical findings. Just by way of illustration, the urine from a patient with typhoid fever who is drinking large quantities of water will be increased in amount, of low specific gravity, show febrile albuminuria and often a few casts.

Polyuria is a constant feature of chronic interstitial nephritis, and is usually most marked during the night. A certain amount of discretion should be used in placing valuation on this symptom, as the patient must not be on a forced water consumption. If physicians would insist on having the twenty-four hour amount recorded in all their urinary examinations, early cases of chronic interstitial nephritis would not be overlooked. The low specific gravity is associated with the polyuria, but it is always advisable to determine the weight of a mixed specimen of the twenty-four hour secretion. A low specific gravity, 1.005 to 1.010, of the early morning urine is especially suggestive, as single voidings at other times may show greater density.

The albuminuria of chronic interstitial nephritis is distinctly intermittent or periodic in the very early stages of the disease. When subjective symptoms first begin to appear the albumin occurs more constantly, and will be found in nearly all cases. I need not say, just in proportion to the care with which it

is sought. Contrary to the teaching in many textbooks, I do not regard one of the most commonly employed tests—Heller's reaction when nitric acid and the urine are brought into contact—as at all sufficient to demonstrate the small, but distinct, traces of albumin in the urine of chronic interstitial nephritis. Only a short time ago a physician brought me a specimen of urine from a woman in whose eyes an oculist had discovered an albuminuric retinitis. He was rather inclined to question the eye specialist's judgment, for the reason that he could not find the albumin ring by Heller's test. I could not, either, even by making use of the horismascope. By boiling the upper part of the urine in a test tube three fourths filled, however, a slight but distinct cloud appeared, which persisted on the addition of a few drops of five per cent. acetic acid. In addition, the urine was of low specific gravity, and the sediment obtained by centrifugalization showed the presence of a few hyaline casts.

In the heat and acetic acid test the albumin is precipitated by boiling as coagulated albumin. The cloud that is produced can be easily recognized by comparing the upper boiled urine with that in the lower part of the tube which is held in the hand. The cloud may be due to phosphates or carbonates, but these are immediately dissolved on adding a few drops of the acetic acid. The acid should always be added after boiling, even if no cloud has appeared, as the urine may not be sufficiently acid for the precipitation of the albumin until the acetic acid is added. Any great excess of acid should be avoided, as it produces soluble acid albumin. When this cloud is faint enough so as to become doubtful we are probably dealing with a normal urine, and this "faintest possible trace" is due to the so called nuclealbumin. This substance is equally well precipitated in the cold by dilute acetic acid, however, and does not often occur in sufficient amount to cause the very distinct cloud that albumin produces. Hastings (T. W. Hastings, Albuminuria, *Medical Record*, July 7, 1906) advises that there be added to the urine one fifth to one sixth its volume of saturated sodium chloride solution before it is heated. This procedure not only serves to bring out the serum albumin in a urine poor in neutral salts, but also holds in solution any nuclealbumin that may be present.

It is very important that the urine to be tested for albumin should be perfectly clear. It is best to examine only a comparatively fresh specimen, but if the urine is at all turbid from the presence of bacteria these can be mechanically removed by mixing the urine with *Kieselguhr*, or infusorial earth, and then filtering. The presence of any quantity of pus or blood in the urine always makes the urine albuminous, and may be very misleading, as no satisfactory method has been devised by which we can estimate how much of the albumin in such a specimen can be attributed to these foreign elements.

The urinary sediment is very scanty in chronic indurative nephritis, and may pass by the way of being even on centrifugalizing. Casts may be found in most cases, chiefly of the hyaline and finely granular variety, but are rarely numerous. Casts of this variety, have but little diagnostic importance, as

the lesion causing cylindruria may be a slight or temporary irritation of the renal parenchyma. The continual presence of casts is of far greater importance. In discussing the significance of casts, Emerson, in his excellent paper on Cylindruria, already referred to, says: "Casts . . . are of much importance in following a case of nephritis or other renal disturbance. For them to be present temporarily and then to disappear entirely means, no matter how alarming their number and variety may have been, a temporary and probably harmless disturbance; for them to continue for days, weeks, or months, no matter how few and how insignificant the onset of the trouble, means chronic nephritis; and for them to remain two years means, it is said, an incurable case." In order to find casts the urine should be as fresh as possible, as they go to pieces more or less rapidly, and in an alkaline urine the search for casts is time thrown away, for they will not be found.

The estimation of the amount of urea excreted in twenty-four hours has been shown to be not only fallacious, but also useless in the diagnosis of nephritis. To refer to the latter contention first, it has been well demonstrated that the urea is not constantly reduced in the urine of chronic interstitial nephritis, but that its excretion is subject to periodic alterations. I have not infrequently found a total excretion of over 40 grammes per twenty-four hours in well developed cases. As a rule the urea excretion is below normal, but such a finding by no means indicates the functional power of the kidney to excrete this substance. The amount of urea that is carried in the blood for excretion is the important factor, and this depends on the amount of nitrogenous food absorbed, and on many other factors, such as presence or absence of fever, vomiting, and diarrhoea, the amount of exercise and sleep, and, in fact, the general catabolism of the whole body. It is only by the most elaborate experiments, with due regard to a large number of conditions, that urea estimations of any value at all can be made.

Attempts to estimate the functional activity of the kidneys by cryoscopy, the degree of glycosuria after the use of phloridzin, and the rapidity of the excretion of methylene blue, cannot be said to have made for themselves a place of value among our diagnostic aids for the recognition of nephritis.

The relative value of the different urinary features of nephritis, as well as the relative importance of the urine compared with the other signs and symptoms of this disease, demand much study and consideration. In the main, one must agree with Cabot when he says: "In my opinion the microscopical and chemical examinations of the urine are of much less significance than the physical. Microscopic and chemical changes are relevant rather to temporary alterations in function than to alteration in anatomic structure. When we are concerned chiefly with the question Has this patient a nephritis or not? what we need most to know is simply how much urine does he pass, by day and by night, and what is the weight of that urine? These facts, together with the presence or absence of dropsy, retinitis, cardiac hypertrophy, and uræmic manifestations, constitute nearly all the evidence at our disposal."

(To Be Continued.)

## THE QUESTION OF SOUR MILK

By LEON HAIM, E. A. M. (France),

Ithaca, N. Y.

*From the Cornell University (Ithaca, N. Y.) Bacteriology Laboratory.*

### *History of Sour or Curdled Milk.*

Nothing is older than curdled milk or sour milk, and nothing seems newer than the application which has been made of it.

It is to be noted that civilized people are the only ones to drink milk fresh or boiled, while fermented milk is almost the only kind used outside the pale of our civilization. The use and origin of curdled milk are older than history. Thus, at the time of the patriarchs, whose longevity was remarkable, mention is made in the Bible of sour milk: "When Abraham saw three men approaching he invited them to enter and offered them some sour milk and some sweet milk and some veal that had just been brought." (Genesis, xviii, 8.)

Later the Greeks and Romans also recognized the strengthening and tonic effects of sour milk, and they performed veritable cures with the special kind of curdled milk called "schiston."

In our time fermented milk is in common use as a daily diet in eastern countries. The writer has seen in Egypt, the Holy Land, and Syria a kind of sour milk called "leben"; in Anatoly, Turkey in Europe, and Greece a kind of sour milk called "yaghourt." Under the name of raiel, he found a kind of sour milk in use in North Africa. He visited in Tunis, North Africa, the bacteriological experiment station under the supervision of the French government, where the preparation of sour milk is scientifically conducted, in order to propagate this wholesome product.

It is said that a kind of sour milk under the name of "yaghourt" is used in Bulgaria; of "leben" in Arabia; of "matzoon" in Armenia; of "gioddu" in Sardinia; of "prostokvasha" and of Varruetz in Russia. Mr. Herman V. R. Ande, from Denmark, wrote to the writer that in Denmark, Norway, and Sweden the people enjoy a dish of sour milk called "tyk moelk," translated, thick milk. The milk is put away in dishes to sour and curdle; then it is eaten usually with rye bread crumbs and sugar.

The following reference has been given by Mr. Chacravarty, of Dacca, Hindustan: "The 'dahi' is a kind of sour milk used as a beverage in India. There are various kinds, and the bacteria bringing about these fermentations have not been studied in detail. It is usually sour, used as a cool beverage, and is supposed to help digestion. Sometimes, Indian and European physicians recommend it as a diet for persons suffering from diarrhoea." Explorers say that sour milk is used by numerous tribes of negroes in Africa.

In almost all these countries, besides being used as a food, sour milk has played and still plays a great part in empirical medicine. The use of fermented milk as food among these people must be the result of judicious observations and experience of numerous generations. This empirical observation may have a scientific explanation, for it is well known how quickly foods decay when exposed to tropical heat. When ingested, germs of putrefac-

tion enter with them, which may continue to develop in the large intestine. Unwittingly these people have used for many centuries, in order to combat intestinal putrefaction, the best and the most efficacious method which is known to science for only a short time.

It is only within a few years that the question of sour milk, as a wholesome food, has attracted the attention of the physicians; and since many studies on the different kinds of fermented milks have been made by various peoples; and on account of satisfactory results of numerous investigations and experiments these wholesome products came into use again.

The first investigations had to do with the "kefir" and "kumyss," which were highly recommended for their great digestibility and tonic effect. Since other similar beverages are known to contain no alcohol, these latter are preferred in most cases.

Sour milk, after being recognized as a wholesome food possessing medicinal properties, has been proclaimed by some people as a remedy for prolonging human life. In connection with this, we shall quote the following few lines, resuming the opinion of Metchnikoff, one of the greatest authorities on the subject:

The fact that many people in all countries and in all ages have consumed large quantities of sour milk, and are so much benefited by its use, is a testimonial to its value. The distinguished African explorer, Negueria, in a letter to me has described his astonishment upon beholding the well preserved appearance and absence of senility among the natives of Massamedes, whom he had not visited for a period of many years. Dr. Lima affirms that among the natives of the region south of Angola there is to be found a very large number of individuals noted for their extraordinary longevity, and although they are thin and dry, the old people are active and capable of making long voyages. Grogoroff, a Bulgarian student, has reported an astonishingly large number of centenarians encountered in a region of Bulgaria where sour milk constitutes an essential element of diet. A long list of centenarians has been collected by chemists in many countries using sour milk as an article of daily diet, etc.

For many years these sour milks have been prepared by first sterilizing milk and afterward inoculating it in a pure culture of lactic acid microbe. I have taken a liberal ration of this sour milk daily and have been exceedingly gratified with the results that I have experienced. After this long trial, I feel justified in expressing a favorable opinion. Many of my friends, among them some who suffered from gastrointestinal troubles and serious kidney diseases, have followed my example. In view of all that has been stated I am naturally led to the opinion that in the struggle against intestinal putrefactions the lactic acid producing bacteria are undeniably serviceable. Finally to proclaim that in this specially prepared sour milk, we possess a remedy against old age, or a means of prolonging human life we must let time, experience, and observation answer this question.

**Sour Milk in Therapeutics.**—The antiseptic action of the lactic acid ferments is a fact commonly known for a long time, and numerous applications of it have been made. Thus, everybody knows the simple process used in many countries since the most remote times of preserving vegetables such as cabbage, cucumbers, beets, fresh beans, olives, etc. The vegetables are placed in jars or other receptacles full of water, to which is added a little salt, and then are kept well sealed. After some time these vegetables, which exposed to the air would have decayed and become unfit for food, undergo by this process the favorable modifications in color, smell, and taste, in their digestibility and preservation, all appreciable

qualities. These products in order to acquire these qualities have undergone a fermentation; and it is proved today that the principal agent of this fermentation is lactic acid ferment. The salt is used only to check temporarily the growth of injurious bacteria which may be present, until the lactic ferments are able to develop freely and in sufficient number to carry on their useful action. The writer has seen in certain Eastern countries and in North Africa people using the same process for preserving lemons, green tomatoes, etc. In the preservation of beets in silos, lactic acid is, in this case too, the principal agent of the process of fermentation. When, for some reasons, the lactic acid fermentation does not take place, the silage has a very disagreeable odor, which causes the cattle to reject this food. The animals feeding on a product of this kind show symptoms of gastric troubles. The continued feeding of such food may cause serious troubles and even threaten the health of the animals.

Metchnikoff tells us that in many countries in which they use sour milk the latter is used for preserving meat. In America older people often sweeten tainted meat by the use of buttermilk, as well as using it for preserving meat for a short time. All these facts, although empiric, are nevertheless significant of the antiseptic power of the lactic ferments.

It is to-day proved that lactic ferment causes the preservation of all these products by preventing the development of the germs of putrefaction. First by the production of lactic acid from hydrocarbohydrates substance, and thus rendering the medium unfavorable to the growth of many species of bacteria preferring neutral medium; second, by its high power of growth, capable of checking and combating the development of other germs.

One of the simplest and most easily demonstrated experiments showing the antagonistic action of lactic acid fermentation towards harmful germs has been made by Dr. Ed. de Freudenreich. Following is his own account:

When sterilized milk is inoculated simultaneously with one platinum loop of cioddu (a kind of sour milk used in Sardinia and one of typhus and cholera cultures, the latter do not develop; the microbes of the cioddu (lactic acid bacteria) rapidly invade the entire field.

Along the same line Conn has made an analogous experiment, which we quote. If sterilized milk is inoculated with putrefactive bacteria it will be badly decomposed and putrefied in a few days. If, however, lactic acid bacteria are present, the putrefaction of the milk by these peptonizing bacteria is prevented.

**Industrial Applications.**—Certain industries, as the manufacture of beer, butter, and cheese, have been the first to profit by these discoveries and by their successful application. Thus, Ducaux in his reputed work, *Microbiology*, iii, expresses himself as follows in speaking of the rôle of the lactic acid ferments in the manufacture of beer:

We know that nearly neutral liquids are easily invaded by countless germs in the same manner as food. The question is how to give in this case, at least as regards the production of the lactic ferment, which in making the liquid acid protect it against other ferments that might produce undesirable changes. The lactic acid fermentation thus becomes an effective fermentation.

The application of the use in pure culture of lactic

acid to the manufacture of butter has contributed to regulate the ripening of cream, to obtain a product uniform throughout the year and capable of being kept longer.

*Application in Medicine.*—It has only been since investigations on the human intestinal flora were begun and the existence of their useful bacteria was recognized that scientists asked themselves whether the beneficial action of sour milk was not due to the presence of lactic acid ferments. Experiments have been conducted by bacteriologists and physicians in order to know whether the presence of lactic acid organisms in the intestine is capable of preventing the development of putrefactions. I shall now give a general summary of these experiments. Before taking up this question, however, I should like to quote the following passage from a work of Metchnikoff:

We ought to try to transform the wild intestinal flora of man into a cultivated flora represented by species that are useful or at least harmless. Numerous attempts are being made to regulate different fermentations by the aid of pure cultures and to improve the manufacture of beer, cheese, butter, etc. It is high time to apply similar methods to perfect the intestinal fermentations of man.

The same learned professor of the Pasteur Institute, in his researches in the problems of old age, undertaken in 1889, observed that the birds which live to be old have no large intestine. His observations had to do with birds which live more than fifty years and with one parrot who died at the age of eighty-four years. By this fact he was led to study the action of the microbes of the large intestines of the human organism. He was struck by the direct analogy existing between the deterioration produced by the toxins of certain harmful microbes of this organ with that produced by alcohol, lead, or mercury. He performed experiments upon young chickens and frogs, and demonstrated conclusively that there exist harmless and harmful intestinal microbes, and that it is necessary to fight the latter and multiply the former. He further proved that young chickens brought up without intestinal microbes waste away and die.

After establishing this point, he showed that the microbes of the human large intestines constitute, in general, a harmful flora. These microbes, by the poisons they secrete and pour into the system, cause various troubles, such as intestinal intoxication and others. At the time of Metchnikoff's experiments gastrointestinal troubles were being treated by anti-septics. But this treatment had the disadvantage of depriving the large intestines of useful microbes and was, therefore, useless or injurious. The problem to be solved, then, was to check the intestinal putrefactions, together with the microorganisms which cause them, without introducing poisonous products into the system, and to leave the useful microbes in the intestine.

While in Bulgaria, Metchnikoff had his attention arrested by the extraordinary longevity of the Bulgarians and the diet of these robust mountaineers, which consisted almost exclusively of curdled milk. After ten years of experiments, Metchnikoff came to the conclusion that the lactic ferments are the most powerful antagonists of the harmful microbes which infest our intestine.

An important point is that these bacteria pass through the stomach, and the gastric juice does not

affect their vitality. It will be seen, therefore, that the result of using this food containing these ferments is the inoculation of the intestinal mucous membrane. Dr. Cohendy (*Comptes rendus de la Société de biologie, C.*) has demonstrated that in case of a person under treatment the lactic acid bacteria is found in the intestine from the third to the fifth day after ingestion; and its presence has been observed there from the twelfth to the twenty-fourth day after the last taking of the ferment.

The practical application of this treatment in cases of intestinal intoxication has produced the results to be expected from the theory. And in cases of infantile diarrhoea, where putrefactive microbes are the cause of troubles, this treatment by inoculation of the large intestine with the lactic acid ferments has met with great success (*Annales de l'Institut Pasteur, 1905*). One more happy application of the use of sour milk as a healthy diet has been made by Hayem, Dujardin Beaumetz in feeding their typhoid fever patients almost exclusively with fermented sour milk. Lately Dr. Litchfield, a noted physician of Pittsburgh, Pa., had, from his own initiative, made some conclusive experiments and acquired valuable experience in the same line. An interesting paper on his experiments has been read before the meeting of Pennsylvania State Medical Association.

We shall set forth the result of Ed. de Freudenreich's studies (*Revue générale du lait, 1905*) on the gioddu, which he has propagated in Italy. In this connection he has made some conclusive experiments on animals. In inoculating guinea pigs with culture of *Bacillus prodigiosus* he saw that these are found in great numbers in the fæces. He fed gioddu to these animals while still continuing to introduce the bacillus, and gradually the latter became very rare in the fæces. He found that the virulence of the *Bacillus coli* in his own intestines was diminished so long as he made use of gioddu. These facts confirm the opinion of Metchnikoff, Huchard, Hayem, and other authors that lactic acid bacteria are the most powerful antagonists of the harmful flora which infest our intestine.

*Sour Milk and Similar Products.*—In this chapter I shall endeavor to define sour milk and to point out the differences between it and similar products.

*Spontaneous Sour Milk.*—Everybody knows that milk kept in a moderate temperature for a short time (longer in winter than in summer) becomes sour and takes a consistency more or less dense. This is spontaneous. Sour milk curdles by natural agents, with a disagreeable taste and smell. Moreover, this product, in the absence of any control in its fermentations, may contain toxic poisons and may present serious dangers of autointoxications. Dr. Bufour de la Rochelle cites such a case (*Bulletin général de thérapeutique, 1907, No. 8*) occurring in a convent where thirty-three out of forty-one nuns were rendered suddenly ill by the use of spontaneous sour milk. So much may be easily understood. The milk when left to itself requires one to one and a half days in summer, and two to three days in winter to sour and curdle. This long time is required because lactic acid bacteria are not usually found in milk freshly drawn from the cow, but appear later. So, before their appearance in

the first period, other species of germs, from the hay, dust, air, body of the cow, etc., appear, some of which in their development secrete toxic poisons, but most of them contain substances which alter the taste and odor of the milk. When lactic acid bacteria appear they find a medium already badly corrupted and in which they cannot carry on any useful action.

**Sour Milk with Pure Culture.**—Sour milk, as it is recommended at present, possessing salutary properties which have been proved, is milk which, after having been freed of all living germs by sterilization, is started with a pure culture of specific ferments. I may add, in connection with this, that there exist numerous bacteria, some even pathogenic, which can produce lactic acid with the hydrocarbon and proteid substances, especially the *Bacillus coli communis*, bacillus of fowl cholera, bacillus of Friedländer, *Bacillus prodigiosus*, etc. The specific lactic acid ferments include a great number of species, differing from each other not only by their morphology, cocci, diplococci, streptococci, rods, but also by their physiological properties. Although there are some which may convert all of the sugar lactose into lactic acid, there are others which can convert but a small quantity. Some render milk sour without curdling it, while others render milk acid and at the same time curdle it by means of an enzyme analogous to rennet. Others, after having curdled the milk, partly liquefy it by another enzyme, discovered by Euclaux, which he called casease. There are some which liquefy gelatin, produce gas, aromatic flavors, etc. Add to this all of the natural factors capable of influencing the work of fermentation, even for one single bacterium such as the kind of milk, its richness, climatic conditions, adaptations, selection, and we may understand why there exist so many varieties of sour milk. This fact is not peculiar to sour milk; there are as many different wines as countries that manufacture them.

In general specific lactic acid ferments, in their work of fermentation, act as follows on the three elements of milk:

a. The casein is coagulated in minute particles, which adhere together, and a certain part of it is dissolved. The following, according to M. Tousart, chemist of the Pasteur Institute, are the quantities of casein and soluble calcium phosphate produced during the fermentation, 5.54 amount of casein in 100 grammes of product.

Test of casein soluble during fermentation:

Time.	Quantity of casein soluble in 100 grammes of product.	Relation of casein soluble.
2 hours	2 grammes 02	37. 81 per cent
8 hours	2 " 08	38. 05 "
24 hours	2 " 24	41. 94 "
48 hours	2 " 40	47. 10 "
54 hours	2 " 64	49. 43 "

0.38 amount of phosphate calcium in 100 grammes of product. Test of the phosphate calcium soluble during the fermentation:

Time.	Quantity of phosphate calcium soluble in 100 grammes of product	Relation of the phosphate calcium soluble.
2 hours	0 grammes 20	68. 41 per cent
24 hours	0 " 27	71. 08 "
48 hours	0 " 28	73. 08 "
54 hours	0 " 30	78. 94 "

His experiments have to do with the ferments of the yaghourt. The casein coagulated by the lactic acid ferment is entirely different from that coagulated by any other acid; in the latter case the casein is in the form of large lumps, sharply separated from the serous portion. And this difference is even more distinguishable by taste and microscopical examinations. Casein coagulated by lactic acid ferment does not assume a compact mass, nor does it precipitate in lumps even with the addition of acids. The casein in this case, we may say, has undergone, by the action of the lactic acid ferment, a partial digestion, and this will explain why sour milk does not curdle in as large masses in the stomach as raw or boiled milk does.

b. In sour milk, one part of the fat is saponified under the action of lactic acid ferment. Thus, in sour milk under certain conditions, the cream does not rise to the top, and its presence is only perceived by the taste, more or less unctuous, according to richness of the milk in fat. A drop of such sour milk under the microscope shows very plainly the number of fat globules to be much less than that of whole milk under any other form. We know that the fat, in order to be assimilated, must undergo the action of pancreatic juice, which saponifies it, and we see that in sour milk one part of the fat is already in an assimilable form.

c. By means of one lactase discovered by Büchner, the sugar of the milk is converted into lactic acid, a product which does not need any previous digestion in order to be assimilated into the body. It will be seen from the preceding that the modifications of the elements of the milk during fermentation give us a product quite different from the milk with which it is made. The changes will explain the high digestibility of sour milk, a well known fact recognized by all experimenters. Dr. Montreius says in regard to this "that sour milk has the advantage over fresh milk in that it has a stimulating effect on the intestine, and thus prevents inconveniences, and I should say even dangers of a milk diet." While raw or boiled milk needs six to seven hours to be digested, sour milk needs only three to five hours. Besides this high digestibility sour milk is not only free from harmful bacteria, but is in the meantime a pure culture of the lactic acid. One c.c. of sour milk may contain 500,000,000 of bacteria and more.

**Rôle of Yeast in Sour Milk.**—Analysis in almost all kinds of sour milk, as they are found in their original countries, shows, besides the lactic acid bacteria, which may be of one or more species, the presence of yeasts. The yeasts, according to the mode of preparation of the sour milk, are utilized for the aromatic products, or, still more, for the alcohol they are able to produce. Thus in the gioddu, leben, yaghourt, besides the lactic acid bacteria, there are yeasts; and these sour milks under usual conditions contain only traces of alcohol, practically we may say none at all.

These quantities of alcohol vary between 0.01 and 0.014 per cent. The same is true for the alcohol when freshly made. But they all possess a *vin* generally flavor with an agreeable taste, due mainly to the individual qualities of the yeast.

The flavor of the zoolak is distinctly different from that of the yaghourt, and this difference depends on the species of yeast. The fact is well demonstrated when these two different yeasts are isolated and started separately in milk or in any other medium, the flavor of the zoolak can be perceptibly changed by taking out its original yeast and replacing it by that of the yaghourt. This has been done in the laboratory.

*Sour Alcoholic Milk.*—In some sour milks the yeasts, which are found with the lactic acid bacteria, are mainly utilized for the alcohol they are able to produce from the lactose, or from any other sugar previously added to the milk. These beverages, according to the mode of preparation, may contain from 0.5 to 1 per cent. of alcohol; they are fresh, sour, effervescent, have a biting taste due to the presence of carbon dioxide, which is in solution. These beverages are much enjoyed by some people. This is the case with the kefir used by the mountaineers in the Caucasus, and the kumyss used by the Tartars and other tribes of eastern Russia and Asia.

It has been alleged that in the grains used for the preparation of kefir are found some undesirable bacteria and that nothing could be done to make these grains pure, i. e., including only the bacteria necessary and indispensable for the work of fermentation. In his experiments in the Dairy Bacteriology Laboratory of Cornell the writer has prepared kefir without using the original grains sold for this purpose. We proceeded in the following manner: After milk previously boiled and inoculated with pure culture of lactic acid was sour, a pure culture of yeast was added in order to develop the alcoholic fermentations. With this process there was no chance of inoculating undesirable bacteria and we could have the kefir ready in a shorter time.

*Medicinal Sour Milk.*—Some authors have recommended for hospitals and medicinal purposes a kind of sour milk made with a pure culture of lactic acid, excluding all yeasts. This is the case with the giöddu which Dr. de Freudenreich has popularized in Italy. There are in this original product a lactic acid bacterium and a species of yeast. He has isolated the lactic acid ferment and prepared with this his special sour milk, which is in use to-day in many hospitals in Italy. The same has been done with the bacillac by Dr. Metchnikoff. These products are undoubtedly as wholesome as the originals, but they do not possess the particular flavor and agreeable taste of the original sour milk from which they are derived. In trying in the laboratory to prepare zoolak from which all yeasts were excluded, we meet the same difficulties. We do not think it worth while to deprive these original sour milks of the appreciable qualities in taste and flavor, for at no time—as far as we know—have traces of alcohol in any food been considered detrimental to health.

*Frauds.*—Unfortunately the public, unfamiliar with the different kinds of fermentation which milk can undergo, is incapable of distinguishing the qualities of the numerous products put upon the market. In consideration of the interest taken by the people in those products, especially in Europe, it has been attempted in many ways to manufacture certain beverages which would more or less resemble sour milk in taste. Such beverages as the following have been

placed upon the market: Milk to which a sufficient quantity of any acid has been added to coagulate it, and afterwards, as it is practised in soda water drinks, adding carbonic dioxide under pressure of 1 to 2 atmospheres. In another case a similar beverage was obtained by adding to milk some sugar and baker's yeast and keeping until fermentation had occurred. In order to prevent such undesirable practices, the public ought to be very careful in their choice and preference should always be given to those possessing the guarantees necessary in such cases. No matter whether the product is manufactured by or under the supervision of a physician, the product should be registered with guarantee of a definite chemical standard and standard of bacteriological compositions, according to the regulation of the pure food law.

#### TRACHOMA—CLINICAL ASPECTS AND SUCCESSFUL TREATMENT

By J. HOBART EGBERT, A. M., M. D.,  
Willimantic, Conn.,

Oculist and Aurist to St. Joseph's Hospital, Willimantic, Conn.;  
Assistant Surgeon, Eye Department, Cornell University  
Medical College Dispensary, New York, etc.

In view of the facts that trachoma is a contagious and not uncommon disease; that recently collected statistics show that about 75 per cent. of untreated cases of trachoma result in blindness<sup>1</sup> and that in some localities (European) 60 per cent. of all cases of blindness result from trachoma<sup>2</sup>; that among cases treated absolute and satisfactory cures have heretofore been altogether too infrequent, and that in many cases long under treatment by approved methods pannus, xerosis, trichiasis, and entropion, with concomitant permanent reduction of vision, have supervened—in view of these facts, it seems entirely unnecessary to offer any apology for calling attention to improved methods of treatment—or, at least, modifications of technique in the application of recognized methods—that are capable of yielding better results than have heretofore generally been attained.

A discussion of the history, ætiology, and general aspects of trachoma is foreign to the purpose of the present paper. Available literature pertaining thereto is already voluminous. Before considering the treatment of the affection, however, we desire to urge consistency and simplicity in classification. Trachoma has been described as acute and chronic; as simple and complicated; as papillary, miliary, and diffuse; as follicular, granular, and mixed; as true and vesicular; as inflammatory and noninflammatory, etc., etc., and has been referred to by different writers under a variety of names, as: Egyptian ophthalmia, granular ophthalmia, granular conjunctivitis, trachomatous conjunctivitis, syndesmitis granulosa, granulated lids, etc. Thus have different observers and teachers endeavored to express their conception of the stages and aspects of the disease; but it is more than a conjunctivitis, it is more than a syndesmitis, and while it may be an "ophthalmia," this word has justly fallen into disuse (or, rather, retained to apply to a definite acute

<sup>1</sup>Scherrenschewsky, *ibid.*

<sup>2</sup>Clark, U. S. Public Health and Marine Hospital Report, 1907.

infectious disease which, when occurring in the newborn is called *ophthalmia neonatorum* and, otherwise encountered, gonorrhoeal ophthalmia), and even though it be not always "rough" (*τραχος*), the term "trachoma" is both distinctive and convenient, and by this simple term this affection should be universally known. Whether the granules be large or small; crowded, coniluent, or diffuse; whether they are in the retrotarsal folds or overlying the tarsus; whether there is present connective tissue hyperplasia or cicatricial contractions—the disease is still one and the same, whatever the variations in clinical aspect resulting from duration and activity of the morbid process, or attributable to idiosyncrasy, racial peculiarity, age or environment of the patient. There is no "acute trachoma"—it is always a chronic affection, though it may, and frequently does, present symptoms peculiar to acute inflammatory processes. Cases of "acute trachoma," resulting in spontaneous cure, are reported, though our own experience—covering hundreds of cases of the disease—would suggest that at least some of the cases thus recorded have been cases of acute follicular conjunctivitis or simple adenomatous conjunctivitis, and not trachoma. Trachoma is always "true"—always seriously real. It is a distinct, local disease, and while its clinical aspects may, in a measure, call for variations in the details of treatment, its successful cure, like that of other definite local pathological conditions, requires the institution and execution of a certain, quite distinctly defined plan. There is unquestionably a tendency on the part of Nature to overcome the disease, and time alone will doubtless effect a termination of the active process in many cases of trachoma, but at what a cost! The low grade of inflammation induced by the disease itself operates so slowly and in such a diffuse manner that, ere the absorption of the products of exudation is effected, serious connective changes have taken place and the destructive process has extended not only to the hyperplastic material but also involved the proper tissues of the lids, occasioning contraction and deformity in these appendages and irreparable damage to the eyeball. Thus, in its natural course, the disease presents three characteristic stages which merge more or less into each other, to wit: (1) a stage of exudation and granulation, (2) a stage of hyperplasia, with connective tissue formation, and (3) a stage of sclerosis and cicatrization.

The treatment of trachoma has long embraced both therapeutical and mechanical measures—the end in view always being to occasion or hasten absorption, destruction, or removal of the products of exudation and hyperplasia. To this end, inflammatory action has generally to be stimulated rather than retarded, and while the usual method is to stimulate persistently and guardedly, decidedly heroic measures have at times been adopted, as the medication of an affected eye with secretion from a purulent ophthalmia or gonorrhoea, or the local use of jequirity or similar active irritant. Bluestone (copper sulphate), directly applied to the granular conjunctiva, has been used, perhaps, the longest and most widely of all chemical agents in the treatment of trachoma, though just why is difficult to understand. Theoretically, it would seem to be an ideal remedy, being both actively stimulating and irritant,

gent, but practically—and we have observed its regular and persistent use on many, many cases for periods of years—we cannot recall a single satisfactory cure resulting from its use. Moreover, our own personal observation and experience with this remedy is by no means exceptional. Nearly thirty years ago a famous Glasgow ophthalmologist wrote: "Sulphate of copper used to be, and I suppose is still, considered the standard remedy for granulations, for in every case of Egyptian ophthalmia, out comes the bluestone, mechanically, as it were. I have seen patients rubbed with bluestone for eight or ten years, until no trace of transparent cornea was left: and I have never seen any satisfactory result accruing from the use of argentum nitras, or any other caustic." In spite of such facts the use of the bluestone goes on, as does the use of other caustics and astringents. There is *one* element of benefit—though an entirely *indirect* one and largely buried beneath the injurious effects of such treat-

ment—that does accrue from the rubbing of trachomatous lids with smooth crystals of bluestone, alum, etc., and that is a mechanical stimulation to absorption from the tissue massage. This mechanical stimulation to absorption and restoration is a feature of the rational and successful treatment of trachoma which we are about to present, but it is much more wisely and satisfactorily accomplished by other agents than copper sulphate crystal or allied substance.

Ordinary lotions and collyria are, alone, utterly inefficient in the treatment of trachoma, though having a definite sphere of usefulness in conjunction with other methods of treatment.

Operative (mechanical) procedures have long been employed by various oculists in the treatment of certain cases of trachoma. The following methods have been practised: Linear scarification of the conjunctiva with subsequent squeezing out of the granules; grattage of the conjunctiva, with or without preliminary sacification; crushing the granules and expressing their contents by means of special forceps, rollers, etc.; excision of the superior cul-de-sac; removal of tarsus and retrotarsal folds. In addition to these operations upon the lids might be mentioned peritomy and peritomy—operations upon the eyeball for the relief of pannus.

Rubbing the granular and hyperplastic conjunctiva with cotton or soft brushes dipped in certain solutions has been found beneficial in the treatment of trachoma, and a 1 in 500 solution of biiodide of mercury is being thus employed by not a few practitioners with more or less satisfactory results. The stimulation from the medication employed is doubtless of benefit, though we are quite certain that the manipulation is the most important feature of the treatment, having obtained excellent results in certain long-standing cases (cases in the second

and third stages of the disease) from massage of the tissues of the lids by rubbing the conjunctiva with a smooth, glass spatula. In carrying out this procedure, it is our practice to thoroughly irrigate the conjunctiva with warm boric acid solution—taking care to include the superior cul-de-sac—and everting the lids, rub the involved portions of conjunctiva—both over the tarsi and in the retrotarsal folds—with the glass spatula, after which the conjunctiva is again thoroughly irrigated. Previous to this treatment, however, most cases require operation for the opening and emptying of all granules and the removal of hyperplastic material. For accomplishing this, we have devised a special curette—or, rather, two curettes, one sharp and one blunt—which are herewith illustrated. These curettes are so constructed that all portions of the involved conjunctiva, including the superior fornix and retrotarsal folds, can be reached, and the edge is so fashioned that while all granular and hyperplastic material can be readily removed, there is little danger of injuring smooth, healthy tissue. The edge of the sharp instrument points downward and backward (toward the handle) to an angle of about 45° and, when the instrument is drawn by the handle, readily engages and removes the abnormal tissue. On the sides of the spoon the edge merges into the flat metal, so as to prevent side cutting or laceration.

In using these curettes, the upper lid is everted over a horn or metal spatula and the sharp curette, the handle of which is held between the thumbs and the first and second fingers much as an ordinary spoon is held, with edge upward, is pushed over the eyeball well up into the superior cul-de-sac and then drawn downward from all directions of a segment of a circle similar to that outlined by the brow. Firm, though gentle pressure, is necessary, and the curetting must be thoroughly done. The blunt curette is now substituted for the sharp one, and the process repeated with slightly more pressure, till the tissues feel smooth under the instrument. The up-turned portion of the conjunctiva is next similarly treated—the edge of the curette now, of course, being turned downward. The lower lid is then likewise freed from all granules. The eye is then thoroughly irrigated with boric acid or normal salt solution, and the other eye operated on—or that may be left until inflammatory reaction in one eye has subsided. Light, iced compresses should be applied to eyes thus operated on during the succeeding twenty-four hours. These should, of course, be intermittently applied lest freezing of the cornea occur. Their continued application for periods of fifteen or twenty minutes every hour will answer well. The lid spatula is not essential, though it will be found of value in many cases, especially in obtaining proper pressure with the blunt curette.

The operation of curetting with the sharp instrument, when done thoroughly, will seldom require repetition, though stimulation through rubbing with the blunt instrument is frequently called for at intervals to promote resolution in the diseased area. This rubbing and massage may often, however, be advantageously carried out by means of the glass spatula.

Local medication is of doubtful value, as already

stated, in the treatment of trachoma. The bichloride of mercury solution (1 in 500) may be applied to the conjunctiva at the time of massaging, and a collyrium of zinc and boric acid given the patient for daily use, to limit and control the general conjunctivitis.

## HOW TO ESTIMATE THE FUNCTIONAL POWER OF THE HEART.

By PAUL C. FRANZE, M. D., L. S. A. (London),  
Bad Nauheim, Germany.

If the functional power of the heart sinks below a certain minimum necessary for overcompensating to a certain degree all the resistances to the circulation, then cardiac failure ensues. Thus prophylaxis, efficient therapy, and prognosis of cardiac disease depend on the estimation of the functional power of the heart. Can this be done, and how? The answer is: Only approximately, and by taking into account all different factors that give evidence as to the heart's capacity for its work.

1. *Blood pressure*.—The height of pressure in the arterial system depends on the total of driving forces and resistances. The former are constituted by the contractions of the ventricles and the elasticity of the arterial walls. The conclusion, therefore, is: in absolute insufficiency of the heart blood pressure must fall. Facts, however, show that this is the rule, but not one without exception. And yet mere fall of the blood pressure is, on the other hand, no criterion of cardiac weakness. Far less is high pressure a sign of a strong heart. The reasons for this are that the former may be due to undertension, the latter to undertension in the arterial system. So far, therefore, the value of blood pressure is minimized as a means of judging the cardiac power. Nevertheless, Gräupner has managed to develop a method of using the changes in blood pressure after specialized exercises in certain groups of muscles (extensors, flexors of the upper and lower extremities) as an aid to estimating the heart's power.

2. *Pulse*.—Frequency, rhythm, and volume of the pulse are quite useless in themselves as criterions of the heart's strength, for they are subject to nervous influences.

3. *Respiration*.—Dyspnoea in rest speaks for cardiac failure. But the reverse, its absence, is no guarantee for a sound heart.

4. *Urine*.—Scanty urine, high specific gravity, and albuminuria are signs of a weak heart, if other sources are excluded. But the absence of these signs is no proof of a sound heart.

5. *Cyanosis*.—This, in a person with sound lungs, is a valuable adjunct to the diagnosis of a weak heart.

6. *The size of the heart*.—As a rule a heart of sufficient functional capacity is nondilated, and when incompensation sets in begins to dilate. So, naturally, the size of the cardiac diagram is in some degree a means of forming an opinion as to the organ's functional capacity. But for this purpose, of course, only the most exact measurements can be relied upon. Such ones can only be made

by x rays, viz., by "orthodiagraphy," or, of late, by "teloröntgenography."

Of all methods and signs which I have mentioned, Gräuper's method, and those by x rays, are the most valuable in themselves. Yet, in my opinion, even in taking all symptoms and methods into account, there is no absolutely exact way to arrive at an opinion regarding the functional power of the heart; it can only be estimated with more or less accuracy.

## Therapeutical Notes.

**Ointment of Yellow Oxide of Mercury.**—If it is desired to prescribe the ointment of yellow oxide of mercury so as to insure the use of a freshly precipitated oxide it is recommended to order that it be made according to the following procedure:

R Corrosive sublimate, ..... gr. xxvii;  
Fused sodium hydroxide, ..... gr. x.

Dissolve the corrosive sublimate in two ounces of warm distilled water and filter. Dissolve the sodium hydroxide in cold distilled water, and into this solution pour slowly, with constant stirring, the mercurial solution. Set the mixture aside in a warm place until the precipitate all subsides. Then decant the supernatant clear liquid, and wash the precipitate by decantation, or on a linen filter, until the washings cease to give any reaction for chloride. Mix the moist precipitate with a sufficiency of a mixture of hydrous wool fat (1) and white petrolatum (3) to make ten drachms. Each drachm contains two grains of yellow oxide of mercury.

**Methods of Administering Salicylic Acid and Sodium Salicylate.**—Salicylic acid is seldom used alone because of its insolubility and its irritant properties, remarks Pouchet in *La Quinzaine thérapeutique*. Internally it is best given in solution as follows:

### I.

R Salicylic acid, ..... gr. xv;  
Glycerin, ..... ʒss;  
Distilled water, ..... ʒiiss.  
Ft. solutio.  
Sig.: One tablespoonful three times a day.

### II.

R Salicylic acid, ..... ʒii ʒii;  
Potassium citrate, ..... ʒss;  
Glycerin, ..... ʒii;  
Aromatic elixir (U. S. P.), ..... q. s. ad. ʒiv.  
M. Sig.: One teaspoonful three times a day.

(The foregoing is supplied when "elixir of salicylic acid, N. F.," is ordered.)

It is mostly in antiseptic applications for external use that salicylic acid is used nowadays, as in the following:

R Salicylic acid, ..... ʒss;  
Starch, ..... ʒiiss;  
Talc, ..... ʒi.  
M. Sig.: Dusting powder.

Other topical applications are:

### I.

R Salicylic acid, ..... ʒss;  
Alcohol, 90 per cent., ..... ʒi;  
Wool fat, ..... ʒi.  
M.

Dissolve the acid in the alcohol and incorporate with the wool fat.

### II.

R Salicylic acid, ..... ʒss;  
Absolute alcohol, ..... ʒiiss;  
Castor oil, ..... ʒv.  
M.

### III.

Oil of turpentine is combined with salicylic acid in ointment form when quick absorption and irritant and hyperæmic effects are desired at the same time:

R Salicylic acid, ..... ʒi;  
Oil of turpentine, ..... ʒi;  
Wool fat, ..... ʒi;  
Benzoinated lard, ..... ʒvii.  
M.

### IV.

For the abortive treatment of boils salicylic acid is used in combination with soap and diachylon plaster as follows:

R Salicylic acid, ..... ʒss;  
Soap plaster, ..... ʒi;  
Diachylon plaster, ..... ʒi.  
M.

Sodium salicylate is the preparation of salicylic acid that is most commonly prescribed for internal use. It is absorbed very rapidly and circulates in the blood in an unaltered condition. According to the *British Pharmaceutical Codex*, when taken internally it increases tissue breakdown, and the nitrogen (urea, uric acid, etc.), sulphates, phosphates, and chlorides in the urine are all increased, but the uric acid is increased out of all proportion to the urea. It is so rapidly absorbed that it is useless as an intestinal antiseptic, and a less soluble form, such as salol, is therefore preferred. Sodium salicylate is usually given in solution in mixture form, as elixir of sodium salicylate, N. F. Pouchet (*loc. citat.*) says the disagreeable and persistent taste of the salt is masked in the following formulas:

R Sodium salicylate, ..... ʒiii;  
Rum (old), ..... ʒii;  
Syrup of orange peel, ..... ʒss;  
Distilled water, ..... ʒi.  
M. Sig.: One tablespoonful every hour.

In combination with extract of licorice it is better tolerated by the stomach:

R Sodium salicylate, ..... ʒi to ʒii;  
Extract of licorice, ..... ʒi to ʒii;  
Distilled water, ..... ʒi.  
M.

## The Value of Antimony in Bronchial Catarrh.

In *The British Medical Journal* for February 20th, page 488, Eustace Smith directs attention to the value of tartarated antimony in the treatment of bronchitis and bronchial catarrh. In catarrhal states of mucous membrane, antimony, he says, is of pre-eminent value. Because in full doses it produces profound discomfort and depression it does not follow that the drug, if given in more moderate and prudent quantity, is not of the utmost efficiency. According to his way of thinking the most erroneous views regarding the treatment of bronchitis prevail among the younger generation of medical practitioners, and he illustrates his point as follows: "A young house physician will order a patient who is suffering from a severe pulmonary catarrh a mixture

containing ammonium carbonate and other stimulating expectorants as a matter of course and in total disregard of the stage of the derangement or the character of the symptoms. But in the management of a bronchial catarrh each class of remedy has its own time for serviceable action and is useless or worse than useless if given out of its due season. The whole treatment of this derangement consists in unloading the congested vessels and setting up free secretion as a first and indispensable step before any attempt to reduce the amount of expectoration can be made. To give ammonia, squill, paregoric, and other stimulating and antispasmodic drugs in the early stage of the catarrh is to make the cough harder and the chest tighter, and greatly to aggravate the discomfort of the patient, if not to produce worse ill consequences. By such means I am convinced that what should have been a mild indisposition has often been aggravated into a serious illness by driving the catarrh further and further into the minuter tubes, and that in children a moderate bronchitis has not seldom been turned into a bronchopneumonia. The use of these remedies should be reserved strictly for the later stages of the catarrh when the cough is perfectly loose from a free secretion of mucus. The earlier remedies have then finished their work, and the time has come for stimulants and astringents to take their place and begin their task of bracing up the relaxed mucous membrane and guiding the complaint to a satisfactory issue." Tartarated antimony acts most efficiently when given in small doses frequently repeated. The most convenient form is the *vinum antimoniæ*, of which a dose of from two or three to ten or fifteen minims, according to the age and condition of the patient, may be given every hour or two hours as long as the symptoms are acute. The drug may be combined advantageously with potassium nitrate, ammonium acetate, spirit of nitrous ether, or similar diaphoretics.

**Paste for Soft Chancre.**—Balzer (*Journal de médecine de Paris*, December 20, 1907) uses the following combination:

R	Zinc chloride, .....	1 part;
	Zinc oxide, .....	9 parts;
M.	Water, .....	q. s.

Use sufficient water to make a paste, which is allowed to remain in contact with the ulcer for twenty-four hours, when it is renewed if necessary.

**For Asthenic Dyspepsia.**—The following aromatic bitter tonic is recommended in *Bulletin général de thérapeutique*:

R	Tincture of cardamom, .....	.3ii;
	Compound tincture of rhubarb, .....	.3ii;
	Sodium bicarbonate, .....	.5i;
	Infusion of calumba, .....	ad .3iv.

M. et Sig.: Dessertspoonful three times a day.

**Harrington's Solution.**—From Dr. Francis B. Harrington, of Boston, we are in receipt of a communication in which he disclaims credit for the introduction of "Harrington's solution," attributed to him in a note on the subject published in this column on March 7, 1908. He advises us that this valuable solution was first brought to the notice of surgeons in general by Professor Charles Harrington, of the Harvard Medical School, and refers us to

*The Transactions of the American Surgical Association*, 1904, vol. xxii, pp. 41 to 51, asking at the same time for a correction of the credit, which we gladly make.

**Local Applications for Orchitis.**—The following local applications are cited in *Bulletin général de thérapeutique*: (1) During the first six days apply the following ointment, rubbing it in gently, and covering the parts afterward with a layer of charpie:

R	Guaiacol, .....	.3iiss;
	Lard, .....	.3ii.

Envelop the testicles in cotton and support them in a suspensory bandage.

(2) At the end of the first week apply the following ointment:

R	Mercurial ointment,	} . . . . .aa 5i.
	Belladonna ointment,	
	Ichthyol,	
	Wool fat,	
M		

**Hæmoptysis**, according to Hirtz and Simon (*Thérapeutique médecine d'urgence; La Tribune médicale*, February 22, 1908), is treated best by complete repose in bed in a well aired room, with appropriate medication for the relief of cough and to check the hæmorrhage. If the hæmorrhage is severe solid food should be withheld and the diet confined to cold liquids such as milk, clear soups, etc. Opium may be given in small doses to allay coughing, according to the indications, as in the following:

R	Syrup of codeine,	} ..... aa 3ii;
	Syrup of belladonna,	
	Orange flower water,	
	Distilled water,	

To control the hæmorrhage ergotin may be given either hypodermatically (ten to fifteen minims of ergotin Yvon) or by the mouth in the following mixture:

R	Ergotin, .....	.5i;
	Syrup of rhatany, .....	.3viiss;
	Orange flower water, .....	.3iiss;
	Cinnamon water, .....	ad .3iv.

M. Sig.: One tablespoonful when required.

Ergotin may also be given in combination with calcium chloride, as in the following mixture:

R	Ergotin,	}	. . . aa 3i;
	Calcium chloride,		
	Orange flower water,		3iiss;
	Cinnamon water,		ad. 3iv.

If the hæmorrhage continues as at first at the end of three or four hours recourse may be had to adrenalin, which is given hypodermatically in doses of five to eight minims of a 1 in 1,000 solution of the chloride repeated three times a day.

To allay the coughing that sometimes comes on after the hæmoptysis is stopped, the following pill is prescribed, to be taken night and morning:

R	Tartarated antimony, .....	} . . . . .aa gr. 1½;
	Extract of hyoscyamus, .....	
	Dover's powder, .....	gr. v;
	Confection of roses, .....	q. s.
M.	ft. pil. No. xii.	

Particularly obstinate cases are treated with doses of ipecac sufficient to cause slight nausea, and by injections of gelatin serum.

## A VALUABLE MODE OF TEACHING.

To interrogate a student at a clinic is doubtless a very efficacious way of compelling him to take in the features of a case to the limit of his capability. Hardly less effective from the point of view of enforcing observation—such observation as Sherlock Holmes always insists upon—while allowing more time to be taken by the student for reflection, is a method set forth in the March number of the *Canadian Practitioner and Review*. Professor Adam Wright, of the Medical Faculty of the University of Toronto, presented the fourth year students of a clinical class with the following extract from Smellie's *Textbook of Midwifery*, and directed them to criticise the treatment recorded as having been employed in the case.

"I was sent for to see a woman, aged forty, who had borne several children before, in 1749. When I came I found the head expelled. I slipped up my fingers and found the os tincte contracted about the neck of the child (which was dead), and endeavored to pull it away, but in vain. I then sent for Dr. L., and I desired him to see what he could do, as my fingers were numbed. He first got one hand in the uterus, and then slipped up the fingers of the other and brought away the child. The woman's pulse before delivery was strong, and she had little flooding. The os had been long gone a quarter of an hour when we were sent for again. They told us that immediately after we went away, which was five minutes after delivery, she was seized with a chill, grew cold, and died. We found her in a room, and told her to lie down, but she could not breathe and died about half an hour after delivery.

As was manifestly due to Smellie's military Dr.

Wright informed the class that the case was not one of Smellie's own, but had been reported to him by another practitioner, whose account he was simply quoting. A student's criticism is appended. For the most part it is judicious, but in the treatment suggested the student wrote: "On arrival, give anæsthetic, dilate the os, and then remove the child." In his remarks Dr. Wright said: "While the administration of an anæsthetic would have been very desirable, this case occurred in 1749." This simple comment should have been quite enough, and doubtless was, to recall the student from any confusion into which he may have fallen as to whether he was expected to suggest what the eighteenth century practitioner should have done in the conduct of the case related or to intimate what he himself would think it proper to do in a similar case occurring at the present time. We venture to say that the student will remember the remark for the rest of his life, and by reason of it will grow to be a better thinker and a better physician than he might otherwise make himself. Retrospective practice, if we may use such a term, has its uses, and the material may come from another man's experience almost as well as from one's own.

## THE GRAND LEGION OF THE RED CROSS.

It is not creditable to us as a people that, whereas the Japanese Red Cross has a membership of 1,300,000, our own has only 10,000 members, and that number is said to be thirty times as great as the membership was three years ago, when the American society was reorganized and placed under government supervision. Perhaps this enormous disparity is due to the great war in which Japan has but recently been engaged. Our own organization seems to have done better in the matter of obtaining money than in that of enlarging its numbers, for we are informed that since the year 1905 it has raised \$4,000,000 and spent that sum in relief work.

There has now been initiated an included organization which appears likely to aid materially in increasing the membership of the Red Cross while doing its own beneficent work in the community. It is known as the Grand Legion of the Red Cross. As a grand legion is made of "four or more legions," we presume there will be a number of grand legions, for each legion consists of only 256 men and 104 officers. Multiplying these numbers by four, we have 1,024 men and 416 officers. In Europe all add, to a grand legion—a partial parallel to serve "in the succor of the sick and injured everywhere and in the prevention, by education, of death by accident and disaster." Perhaps, however, the sympathy from which we are drawing our

information pertains only to the State of New York and its branch of the National Red Cross, but, even at that, what can 1,040 men do "in the succor of the sick and injured everywhere"? They can do much, of course, but not a tithe of what ought to be done. Therefore, we repeat, there will probably have to be many grand legions, even in the State of New York, though the statement that a grand legion is made up of "four or more legions" gives us the hint that a great number of legions may be included in a grand legion.

The objects of the organization are said to be: To help the sick and injured when physicians are not at hand, and also to assist the latter; to help care for those sick or injured in great public celebrations; in time of war to serve under the Army Medical Department in field, hospital, and camp; to spread a knowledge of simple hygiene and assist in the struggle against tuberculous disease; to teach ordinary care and forethought for the prevention of accidents; to teach what to do in moments of danger in order to prevent injury or loss of life, as in panics and street crushes; and to help establish a higher regard for human life. Each legion is commanded by a director in chief, and each relief column (of which there are four in a legion) by a director, and these officers must be physicians.

The objects stated are certainly such as all good citizens have at heart, and we hope that enough legions will be organized to assure their accomplishment, also to swell the membership of the National Red Cross, for every member of a legion must also be a member of that body.

#### IRON IN CHLOROSIS.

To those who would view chlorosis in the light of a severe anaemia and nothing more the hypothesis that it is in reality a specific disease, due to a mechanism differing essentially from others which lead to a condition of grave anaemia, will come as something new. Yet such is the point of view adopted by a number of modern students, the most recent expression from whom comes to us in a study by F. W. Warfinger, formerly director and senior physician of the Sabbatsberg Hospital, of Stockholm (*Nordiskt medicinskt Arkiv*, 1907, 3).

For years chlorosis has been grouped with the grave constitutional disorders, due to fundamental nutritional disturbance, and formerly often associated with tuberculous or leprosy processes. According to this view, the derangements of the function of nutrition lead to the grave anæmic changes which are present in this disorder. The present author, on the contrary, says that chlorosis should

not be included among the chronic anæmias, with which it has been allied, and to which it has few resemblances, save that of a modification of the constitution of the blood, but that it is to be considered as an entirely specific, independent disease, arising spontaneously, particularly in young women, without any apparent cause, and presenting a definite clinical picture. This view of the nosological position of the disease is of the utmost importance from the standpoint of treatment.

Inasmuch as it is a matter of clinical knowledge that the disease appears very frequently in persons of good nutrition, and that experience shows that the best of dietetic means are usually inefficient, it would appear that chlorosis, as has been held in so many quarters, is not to be regarded as an inanition anæmia. Neither is the author disposed to accept the idea of its being of nervous origin, or Rokitansky's hypothesis that it is due to an insufficient development of the circulatory and genital systems. For other good and sufficient reasons he rejects heredity and digestive disturbances as essential ætiological factors. Clinically, true chlorosis is characterized by certain very striking features. Its appearance practically only in young women about the period of puberty, a peculiar whitening of the skin and of the mucous membranes, the lack of alteration in the nutrition of the body, a cardiac murmur, and a striking change in the constitution of the blood are the most marked symptoms.

The cause of the lowering of the hæmoglobin percentage and of the diminution in the number of red cells is still unknown, but the author believes that his study has demonstrated that there is a defect in the internal composition of the plasma of the red blood cell by which an interference takes place with the assimilation of the necessary amount of hæmoglobin. This change in the constitution of the plasma is due to a poison of some nature which reduces the catalytic power of the protoplasm of the red blood cell, in which is brought about the formation of hæmoglobin from the hæmatogens of the food. This poison, according to the hypothesis of the author, arises as a consequence of an acute infectious disease, probably of parasitic origin, since the disease is characterized by a febrile course, a tendency to recurrence, and epidemic features.

The therapeutic efficacy of iron he adduces as an argument in favor of his hypothesis. Its action is not local, and hypodermic injections are as efficient as its internal administration. Organic as well as inorganic preparations are valuable, but only when they give a distinct chemical reaction of iron. The pharmacological action of iron takes place in the fluids of the body, and only after dissociation of the iron ions, which ions act as catalyzers, hastening

the reduction of the already existing toxic substances which hinder hæmoglobin formation. The iron should be given for at least six weeks in order to counteract all the poison thoroughly, and, in the author's opinion, should be administered in large doses, since by far the greatest amount passes through the gastrointestinal canal unabsorbed.

### THE ESSENTIAL IDENTITY OF TUBERCLE BACILLI.

In rather a long article on the variability of the tubercle bacillus, published in the February number of the *Revue de la tuberculose*, Professor S. Arloing argues in favor of its essential identity, however great may be its temporary variations in morphology, virulence, and other characters. He reminds us that in the year 1884 he maintained the variability of human tuberculous disease in virulence, and that his contention was opposed more or less vigorously until 1902, when the bacteriologists suddenly became agreed on the main question, differing only as to the limits of variation beyond which the bacilli ought to be arranged in distinct groups. Were there, for example, it was asked, a human type and a bovine type, rigorously defined, among the tubercle bacilli of the mammalia, and were there also special types for birds and for fishes, impossible of inclusion under either of the others?

Arloing now declares himself more and more convinced that the tubercle bacillus is a single entity, that the species or types recognized and insisted on by many observers are only temporary strains or varieties, and that their apparent lack of change lasts no longer than the conditions in the matter of media under which they were formed. In effect, he says, the facts now adduced by him demonstrate the greater or less facility with which the types admitted by many authors are modified in every particular, and at what point types at first distinct come to resemble each other in many respects under the influence of natural or experimental modifiers.

In conclusion, he thinks it must be admitted: 1. That types are rarely perfect in distinguishing features. 2. That they are accompanied by an almost indefinite series of individuals which, by their growth, their form, and their virulence, are capable of passing the one into the other. 3. That natural variability is sufficient to explain the usual characters of virulence in the bacilli of mammalia and in those of birds. 4. That there would be positive danger, from the medical and the hygienic point of view, in basing principles to be applied in the prevention of tuberculous disease upon differences that are essentially changeable.

If M. Arloing is correct in his contention, the inference can hardly be avoided that the tuberculous disease of human beings may be conveyed to cattle and that of cattle to the human subject. Such an inference, coupled with the growing evidence to support the view that human infection is incurred more commonly through the digestive tract than was until lately supposed, must accentuate our endeavors to eliminate tuberculous meat and milk from our food supplies, and that elimination, indeed, ought to be effected as a mere matter of precaution, quite apart from final solutions of the problems of bacteriology.

### PLAGUE INVESTIGATIONS IN INDIA.

In our issue for September 7, 1907, we called attention to the special number of the *Journal of Hygiene* devoted to the report of the India Plague Commission. The December number of the same journal is devoted to further reports of the Plague Commission. The first article is a digest of the recent observations on the epidemiology of plague. Then follows the original work of the India Plague Commission. They first describe the epidemiological observations in the city of Bombay; then they report observations made in the villages of Sion, Wadhala, Parel, and Worli, suburbs of Bombay; then follows a discussion of the manner of the spread of the infection in Bombay and of the infectivity of houses; and, finally, there is a description of epidemiological observations made in the villages of Dhand and Kasel in the Punjab.

The entire work is, of course, done from the viewpoint of the epizootics in *Mus decumanus* and in *Mus rattus* and their conversion into human epidemics by the agency of the rat flea, *Pulex cheopis*. The methods of the examination of rats are similar to those described by Kitasato in a paper published in the *New York Medical Journal* for July 7, 1906. The method of collecting fleas for examination is ingenious and original.

The names of the writers of the reports are suppressed, most unjustly, we think. It appears to us that the important points are these: First, there are distinct *Mus decumanus* epizootics and *Mus rattus* epizootics, which are followed by distinct human epidemics. Second, these epizootics are followed by the epidemics in from seven to ten days. Third, the rat flea is the agent of spread of the epizootic from *Mus decumanus* to *Mus rattus*, and of the conversion of the latter epizootic into a human epidemic. Fourth, the way to stop plague is to exterminate rats.

These facts are those that are guiding our own authorities in their efforts to stop the spread of

bubonic plague on the Pacific coast. While no cases of human plague have been discovered there for more than a month, the work of exterminating rats goes on at the rate of seven thousand a week in San Francisco alone. Rats continue to be found infected with *Bacillus pestis* (*Public Health Reports*).

### "DR. MAGNUM."

"Dr. Magnum," it may be allowed, has a festive sound, but to see it substituted for *Dr. Magnan*, of the Ste.-Anne, in a Paris press dispatch "by telegraph to Clifden, Ireland, thence by wireless," as it was in one of the newspapers last Sunday, inclines one to wonder whether the error is to be imputed to the cable or to the Marconi system. From the substance of the dispatch it is to be gathered that Dr. Magnan's jubilee was to be celebrated on Monday, but throughout he is called "Dr. Magnum."

### Obituary.

MR. DANIEL SIDNEY APPLETON,  
of London.

Mr. Appleton died on Wednesday, March 18th, at his residence, in London, at the age of forty-seven years, of cardiac disease. He was a member of the firm of D. Appleton & Co., and during the latter years of the many that the *New York Medical Journal* was published by that house he was particularly devoted to its interests. He was of the third generation of those Appletons who were engaged in the publishing business. Some seven years ago he became the London representative of the firm, and he also entered upon a publishing career of his own in that capital. With the ready adaptability of our countrymen he took kindly to life in London, where he made many friends. The deceased gentleman was a wise man of business, and, above all, he was personally most attractive and amiable.

### News Items.

**Changes of Address.**—Dr. Thompson J. Trueman, to 209 Bridge street, Brooklyn, N. Y.; Dr. B. Franklin Ross, to 35 South Nineteenth street, Philadelphia.

**The Society of Physicians of the Village of Canandaigua, N. Y.**, held a meeting on the evening of March 12th. Dr. O. J. Hallenbeck read the paper of the evening on Spinal Injuries.

**The Franklin District, Mass., Medical Society.**—At the March meeting of this society, which was held in Greenfield on Tuesday, March 10th, Dr. Clara M. Greenough read a paper on Functional Dysmenorrhœa.

**Buffalo Academy of Medicine.**—The regular meeting of the Section in Pathology was held on Tuesday, March 17th. The programme included a paper on Gangrenous Inflammation of the Appendix with Spontaneous Discharge into the Small Intestines, by Dr. A. L. Benedict, and a paper on Epithelial Tumors of the Skin and Exposed Mucous Membranes, by Dr. A. H. McGlannan, of Baltimore.

**American Urological Association.**—The New York Society will hold a stated meeting at the New York Academy of Medicine on Wednesday, March 25th, at 8:30 p. m. The paper of the evening will be read by Dr. Ramon Guiteras on Tuberculosis of the Kidney.

**Rochester, N. Y., Academy of Medicine.**—A meeting of Section III, which embraces obstetrics, gynecology, and pædiatrics, was held on Wednesday evening, March 18th. Dr. C. S. Starr reported a case of chorea at term, two cases of eclampsia, and an alleged case of abortion.

**Hartford, Conn., Medical Society.**—The Surgical Section of the society will meet on Monday, March 23d, at 8:30 p. m. Dr. Roswell Park, of Buffalo, will deliver an address on the Modern Aspect of the Cancer Problem, which will be followed by a general discussion. At the close of the meeting a reception will be tendered Dr. Park.

**American Medicopsychological Association.**—The sixty-fourth annual meeting of this association will be held in Cincinnati, Ohio, on May 12th to 15th. The programme includes a long list of papers by eminent neurologists, and the meeting promises to be one of especial interest. Dr. Charles W. Pilgrim, of Poughkeepsie, N. Y., is the secretary of the association.

**Statistics of Operations for the Cure of Aneurysm.**—Dr. Rudolph Matas, of No. 2255 St. Charles avenue, New Orleans, writes that he is compiling the statistics of operations for the cure of aneurysm by the intrasaccular method (endoaneurysmorrhaphy), and will be obliged to all surgeons who have had experience with this operation for brief reports of their cases.

**Syracuse, N. Y., Academy of Medicine.**—A meeting of this academy was held on Tuesday evening, March 17th. Dr. J. C. Palmer read a paper on the Inspection of Schools in Syracuse, Dr. Jesse Heiman read a paper entitled Personal Experiences in School Inspection, and Dr. D. M. Totman read a paper on Milk Inspection. The general discussion, which followed the reading of the papers, was opened by Dr. Nathan Jacobson.

**Charitable Bequests.**—By the will of William B. Scott, of Bryn Mawr, Pa., St. Christopher's Hospital, of Philadelphia, receives \$25,000 for a permanent fund. The Children's Seashore Home, of Atlantic City, the Bryn Mawr Hospital, and St. Christopher's Hospital are reversionary legatees.

By the will of Mrs. Sarah E. Thomas, the Presbyterian Eye, Ear, and Throat Charity Hospital, Baltimore, receives \$100.

**The Norfolk, Va., Antituberculous League.**—At a recent meeting of the board of directors the plan of establishing a separate hospital for tuberculosis patients at the city almshouse was endorsed, and it is believed that the necessary appropriation will be made by the council. Clinics are held daily under the auspices of the league, and are conducted by Dr. J. W. Hunter, Dr. J. J. Miller, Dr. W. P. Smith, and Dr. Charles R. Grandy, each taking a turn in regular order.

**Medical Society of the County of Kings.**—At a meeting of the Section in Pædiatrics, held on Friday evening, March 20th, the programme included the following papers. A Review of English Pædiatric Literature for 1907, by Dr. John F. Crawford; A Review of the German Pædiatric Literature for 1907, by Dr. Alexander Spingarn; Chronic Intestinal Infection in Infants and Young Children, and Report of a Case of Rudimentary Fingers, by Dr. E. H. Bartley.

**The Mortality of Connecticut.**—According to the Monthly Bulletin of the Connecticut State Board of Health for the month of February, 1908, there were during the month 1,511 deaths from all causes, a decrease of 44 from the preceding month, and an increase of 8 over the same month in 1907. The annual death rate in 1,000 of population was 17.5 for the large towns, 18.6 for the small towns, and 17.7 for the whole State. There were 282 deaths reported from infectious diseases.

**Alumnæ Association of the New York Medical College and Hospital for Women.**—The regular spring meeting of this association was held on Wednesday, March 18th, in Brooklyn, at the residence of Dr. J. V. H. Baker, 512 Bedford avenue. Dr. Clarice J. Parsons, of Springfield, Mass., read a paper on Women Physicians in Small Cities, which was followed by a general discussion. Dr.

**The Health of Philadelphia.** During the week ending May 11, 1918, the following communicable diseases were reported to the Bureau of Health: Malarial

whooping cough, 10 cases, 4 deaths; pulmonary tuberculosis, 137 cases, 77 deaths; pneumonia, 98 cases, 67 deaths; erysipelas, 10 cases, 3 deaths; puerperal fever, 5 cases, 2 deaths; cancer, 13 cases, 18 deaths; mumps, 15 cases, 0 deaths; tetanus, 1 case, 0 deaths. The following deaths were reported from other transmissible diseases: Tuberculosis, other than tuberculosis of the lungs, 12; diarrhoea and enteritis, under two years of age, 14. The total deaths numbered 562, in an estimated population of 1,532,738, corresponding to an annual death rate of 19.01 in 1,000 of population. The total infant mortality was 115; under one year of age, 92; between one and two years of age, 23. There were 36 stillbirths; 22 males, 14 females.

#### Society Meetings for the Coming Week:

**Monday, March 23d.**—Medical Society of the County of New York.

**Tuesday, March 24th.**—New York Otolological Society; New York Medical Union; New York Dermatological Society; Metropolitan Medical Society of New York City; Buffalo Academy of Medicine (Section in Obstetrics and Gynecology).

**Wednesday, March 25th.**—New York Academy of Medicine (Section in Laryngology and Rhinology); New York Surgical Society.

**Thursday, March 26th.**—New York Academy of Medicine (Section in Obstetrics and Gynecology); Brooklyn Pathological Society; Hospital Graduates' Club, New York; New York Celtic Medical Society; Brooklyn Society for Neurology.

**Friday, March 27th.**—New York Clinical Society; Academy of Pathological Science, New York; New York Society of German Physicians.

**Saturday, March 28th.**—New York Medical and Surgical Society; Harvard Medical Society, New York; Lenox Medical and Surgical Society, New York; West End Medical Society.

**College of Physicians of Philadelphia.**—At a meeting of the Section in Otolaryngology, held on Wednesday evening, March 18th, the following papers were read: Tertiary Syphilis of the Pharynx, Tonsil, and Soft Palate, Epiglottitis and Vestibule of the Larynx, with Membranous Formation Simulating Vincent's Angina, by Dr. D. Braden Kyle; Position of the Patient in Operations on the Nose and Throat, by Dr. Arthur A. Bliss; Some Laryngeal Complications of Typhoid Fever, by Dr. Joseph S. Gibb.

The Section in Ophthalmology held a meeting on Thursday evening, March 19th. The programme was as follows: Dr. Howard F. Hansell read a paper on Burn of Both Eyes by Electricity, and exhibited a patient; Dr. William Campbell Posey reported a case of paralysis of the extraocular muscles in exophthalmic goitre, and a case of homonymous hemianopsia in the macular regions. Dr. S. D. Risley reported two cases of interstitial keratitis associated with cretinoid conditions; Dr. Wendell Reber read a paper entitled A Probable Congenital Circumscribed Defect in the Choroid with Anomalous Pigment Arrangement; and Dr. William Zentmayer read a paper entitled Restoration of the Contracted Socket.

**Over Seven Thousand Dollars in Prizes for Exhibits and Essays Relating to Tuberculosis.**—Five prizes of \$1,000 each and seven of \$100 each are offered by the International Congress on Tuberculosis as follows: 1st, For the best evidence of effective work by a voluntary association for the prevention or relief of tuberculosis; 2d, for the best exhibit of a furnished house for a family, or a group of families of the working class; 3d, for the best exhibit of an existing sanatorium for the treatment of tuberculosis among the working classes; 4th, for the best exhibit of a dispensary or kindred institution for the treatment of the tuberculous poor; 5th, for the best exhibit of a hospital for advanced pulmonary tuberculosis. The Congress also offers prizes of \$100 each for seven educational leaflets of from one to two thousand words, addressed to (a) adults generally, (b) teachers, (c) mothers, (d) indoor workers, (e) dairy farmers, (f) grammar school children, and (g) primary school children, the latter to be pictorial in character. The Smithsonian Institution offers a prize of \$1,500 for the best treatise submitted on the Relation of Atmospheric Air to Tuberculosis. Numerous medals are also

offered for exhibits in allied lines. Full details regarding the forms in which essays are submitted will be furnished by Dr. Thomas G. Ashton, 1814 South Rittenhouse Square, Philadelphia, secretary of the Committee on Prizes.

**The American Society of Tropical Medicine.**—The fifth annual meeting of this society will be held at the Johns Hopkins Hospital, Baltimore, on Saturday, March 28th. At the morning session Dr. James M. Anders, of Philadelphia, will deliver the presidential address on a Brief Review of the Year's Progress in Tropical Medicine; Dr. Joseph McFarland will read a memoir of the late Dr. James Carroll; Dr. Charles Wardell Stiles, of Washington, D. C., will read a paper, the subject of which is not announced; Dr. Bailey K. Ashford, of Washington, D. C., will read a paper entitled Puerto Rico as a Field for Research in Tropical Medicine; and Dr. R. H. Strong, of Manila, will read a paper on Vaccination against Plague. In the afternoon the election of officers and members will be held, and the following papers on the prophylaxis of malaria will be read: Quinine Prophylaxis, by Dr. William S. Thayer, of Baltimore; Mechanical Prophylaxis, by Dr. Charles F. Craig, of Fort Leavenworth, Kansas; Mosquito Extermination, by Dr. L. O. Howard, of Washington, D. C.; Strongyloides Intestinalis in Philadelphia, by Dr. Judson Deland, of Philadelphia; Twenty Years' Experience with the Hypodermic Use of Quinine and Urea Hydrochloride in Malarial Infection, by Dr. S. Solis-Cohen. The following papers will be read by title: A Biographical Note of Dr. Louis Beauperthuy, by Dr. Aristides Agramonte, of Havana; Some Notes on a Collection of Entozoa Made by Dr. F. Creighton Wellman in Portuguese West Africa, by Dr. Henry B. Ward, Lincoln, Neb.; The Pathogenesis of Pernicious Malaria, by Dr. William H. Deaderick, of Marianna, Ark.; Clinical Charts of a Case of Quartan Malarial Fever observed in West Africa, by Dr. F. Creighton Wellman, of Breyella; and a History of a Case of Malarial Fever, Algid Form, Choleraic Type, by Dr. R. H. von Emdorf, of New Orleans.

**Meetings of Sections of the New York Academy of Medicine.**—A meeting of the Section in Ophthalmology was held on Monday evening, March 16th. The paper of the evening was read by Dr. E. S. Thomson on the Diagnostic Value of Tenderness in the Ciliary Region.

At a meeting of the Section in Medicine, which was held on Tuesday evening, March 17th, Dr. Lawrason Brown, of Saranac Lake, read a paper on Cardiac Complications in Pulmonary Tuberculosis; Dr. Thomas B. Fletcher, of Baltimore, read a paper on the Cerebral Complications of Ulcerative Endocarditis; and Dr. Alfred Stengel, of Philadelphia, read a paper on the Clinical Features of Myocardial Disease. The discussion which followed was participated in by Dr. W. Gilman Thompson, Dr. Alexander Lambert, and Dr. Henry Koplik.

The Section in Genitourinary Surgery held a meeting on Wednesday evening, March 18th. Dr. Eugene Fuller read a paper entitled A Reminder that Fatal or Serious Results May Follow Operative Treatment of Bubo, and Dr. L. Levin read a paper entitled Renal Pyuria Without Apparent Lesion in the Kidney.

A meeting of the Section in Orthopaedic Surgery was held on Friday evening, March 20th, and papers were read as follows: Some Observations on Suppurative Conditions in the Joint Regions in Infancy and Young Children, by Dr. Linnaeus E. La Fetra; Serotherapy in Infectious Arthritis, by Dr. John Torrey; and the Diagnosis of Joint Infection, by Dr. P. William Nathan.

The Section in Obstetrics and Gynecology will meet on Thursday evening, March 26th. The following programme has been prepared for the meeting: Dr. Eden V. Delphey will present a unique specimen of an asexual monster, Dr. H. J. Boldt will present a specimen of tubal abortion, and Dr. C. C. Sichel will present a specimen of carcinoma of the uterus complicated by pus tubes and adherent appendix. Dr. Eugene C. Savidge will read a paper entitled The Problem of Uterine Cancer, and the following reports of cases will be given: Inverted Appendix, reoperated, with microphotograph, by Dr. H. D. Furniss; Amputation of the Cervix under Hypnosis, by Dr. C. F. Adams; Right Ovarian Cyst Complicated by Appendicitis and Distended Gallbladder, by Dr. C. C. Sichel; Serous Fluid (Pelvic) encapsulated two months after Supravaginal Hysterectomy, by Dr. Le Roy Broun; and Small Ovarian Abscess. Rupture while Removing, by Dr. Le Roy Broun.

## Pith of Current Literature.

### THE BOSTON MEDICAL AND SURGICAL JOURNAL.

March 12, 1908.

1. The Genesis and Nature of Hysteria: A Conflict of Theory. By J. W. COURTNEY.
2. Some Clinical Observations on the Diagnosis and Treatment of Exophthalmic Goitre. By JAMES MARSH JACKSON and LOUIS GRAY MEAD.
3. Strictures of the Esophagus Dilated through the Esophagoscope. Report of a Case. By T. PAYSON CLARK.
4. A Case of Gastric Symptoms of Reflex Origin. By RICHARD F. CHASE and JOHN T. BOTTOMLEY.

**1. The Genesis and Nature of Hysteria: A Conflict of Theory.**—Courtney reviews the theories of Freud, Babinski, Janet, Prince, and Pullier, and gives the definition of hysteria put forward by these authors. He states his own ideas as follows: He believes that hysteria is the clinical expression of a simple adynamic condition of the brain, and that in our part of the world we rarely see more than a *forme fruste* of the classical picture. By this he means that the somnambulistic phenomena (which, Janet says, constitute more than half the so called accidents of hysteria), the complete abulias, the deliria, the paralyzes, and contractures, even the absolute hemianesthesias and amauroses, are genuine rarities. In view of these observations he is firmly convinced that the generally unfavorable prognosis laid down by American writers on hysteria represents the teaching of the French school rather than an independent conviction based on their own experience. He is also satisfied that in environment and psychotherapy we have two agents that are absolutely adequate for the cure of practically every case we meet in our daily work. His conception of psychotherapy is based on this fact, that the infusion of force and activity into brain cells is by no means a purely endogenous process. This truth was obvious to the mind that first conceived the idea of placing a band of music at the head of a regiment of soldiers; and we are all familiar with the tremendous dynamogenic capabilities of a patriotic tune. A waltz measure, for some of us, possesses the same energizing quality; for others the spoken or written word, the personal example, are all sufficient. Psychotherapy stands for anything and everything that acts upon the intellect and the emotions in a way to recharge depleted brain cells. As to the etiology of hysteria he held that it is logical to assume that from a remote period in history, down as far back as the time when the misbegotten term "hysteria" was conceived in the medical mind, human beings of both sexes have been the victims of bodily injuries, and that these injuries have been incurred under circumstances quite as harrowing to the emotions as any which obtain today. In the face of this logical assumption, it seems to him nothing short of marvelous that medical history should be so absolutely barren of reference to trauma as a cause of hysteria, and to the time when surgeons had begun to direct the great commercial enterprises of the world and were held responsible by law for the safety both of those in their employ and of those

whom they undertook to convey from one place to another. There is to our author a sinister significance in the rapid growth in importance attached to bodily injuries in the causation of hysteria from that time to the present, and a sinister significance in the facility with which bodily injuries of the most trivial sort appear to be capable of producing this untoward result in persons previously unemotional and whose family history is so universally free from everything that might suggest nervous or mental deviation.

**2. Some Clinical Observations on the Diagnosis and Treatment of Exophthalmic Goitre.**—Jackson and Mead are not in favor of sending early cases to the surgeon. The results of medical treatment are too favorable, from 70 per cent. to 80 per cent. of the cases being cured by it. This is especially true in the rudimentary forms; better in the form which develops gradually than in the form which develops suddenly with full force; better in the old than in the young. But notwithstanding the good results from medical treatment there will always remain a certain number of cases for the surgeon, viz., when the thyroid gland becomes so large that it produces symptoms of compression or when the patient gets rapidly worse on medical treatment. Organic heart changes and bad general condition are surely contraindications to operation.

### THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

11. Fistulous Tracts, Tuberculous Sinuses, and Abscesses. By J. H. HARRIS.

**1. The Chemical Control of the Body.**—Starling, in his review of the physiological and chemical investigations, we may assert that in the employment of these investigations, the method employed by Nature herself, and, indeed, that a large share in the wonderful coordination of the activities of different parts of the body, which determine their mutual co-operation for the common weal of the organism, is secured by the presence and regulation of chemical substances which are strictly analogous to the drugs administered therapeutically to the human body.

treatment of diseases. As an illustration of this fact he cites secretin, a chemical substance that excites pancreatic reaction. This body can be regarded as a type of a whole group of chemical messengers, which, formed in one organ, travel in the blood stream to other organs of the body and effect correlation between the activities of the organs of origin and the organs on which they exert their specific effect. For these chemical messengers the name of "hormone" has been suggested. Ehrlich divided the chemical agents which act on the organism into two classes, the toxins and the drugs. There is one marked distinction between the two groups: The toxins cause the formation in the organism of antibodies, tending to produce immunity, while in the case of the drugs, though with some a limited degree of tolerance may be produced, there is no evidence of the production at any time of antitoxic substances in the treated animal. The hormones, acting constantly as chemical messengers from one organ to another by way of the blood, cannot produce antibodies that would abolish their function, and must necessarily, therefore, belong to the class of drug substances. Their action must also, in all probability, be ranked with the purely chemical processes, rather than with those mixed chemical and physical processes which determine the formation of absorption compounds and distinguish the interaction of one colloid with another, as well as of toxins with the animal cell or with their corresponding antitoxine.

**7. American Mineral Waters.**—Crook compares the analyses of American commercial mineral waters, recently published in *Bulletin 91* of the Bureau of Chemistry, of the United States Department of Agriculture, with those of the advertised analyses. He comes to the conclusion that a great majority of the advertised analyses of our mineral waters were made many years since when methods were not so exact as they are at the present day. Some mineral springs are sensibly influenced by the wetness or dryness of the season, both in strength and in volume; the greater the volume of the water the weaker it is in mineral ingredients; examinations of such springs at different stages would undoubtedly yield dissimilar results. While many springs are of deep origin and show no apparent fluctuations in their rate of flow, we have no positive proof that even these have not become more or less modified in character during the long period since the old analyses were made. The subterranean aqueous current, which constitutes a spring when it reaches the surface, cannot be counted on continuously to come in contact with earth strata which yield a uniform product to its solvent power. Underground streams, as well as those on the surface, are liable to change their course, and, while losing certain of their former contents, may acquire new ones. The fact must not be overlooked that the government analyses were made in each case from samples purchased in the open market. It is, therefore, possible that some of the waters examined by the bureau chemists were spurious or adulterated. All of our medicinal springs should, therefore, be submitted to analysis at least once in ten years until we are able to arrive at a correct estimate of their potency, and

whether they are gaining or losing in strength. No enterprising mineral spring proprietor, animated by a desire to put forth a reliable product, can object to the expense, repeated at intervals so widely separated. The decennial revisions of our works on *matéria medica* and pharmacy should present a brief account of the mineral waters conforming to ethical rules, so that the medical practitioner may be in possession of as authentic and authoritative a source of information regarding these as he has in case of other therapeutic agents.

**8. The Oatmeal Diet in the Treatment of Diabetes Mellitus.**—Herrick confirms von Norden's statement for the oatmeal diet. While occasionally the stomach will rebel and refuse to tolerate this food for any great length of time; while the diet is not suited to all cases, being of least avail in the milder forms; while it fails even in some of the severer types, and while no claim for a cure of diabetes can be made, this diet still remains a most valued therapeutic agent for the warding off of impending coma in the severer types of diabetes and for assisting in the establishment of a tolerance for carbohydrates. In the milder types of diabetes he has so far seen no ill effects follow its use, but the benefits have been trifling. His experience in using it in the diabetes of moderate severity has in general been favorable, it being of especial help in establishing tolerance for carbohydrates. In the diabetes of children, if employed early, it seems to exert a usually favorable influence.

**10. The Use of Anthracite Coal Ash as a Surgical Dressing.**—Clark has made experiments with anthracite coal ash pads as surgical dressings. He concludes that in cases where gauze cannot be obtained or the expense is too great, ash pads form a good substitute. In freely discharging sinuses and suppurating wounds the discharge will be well taken care of. When the discharge is thick and gummy, or where weight or bulk of dressing is contraindicated, they should not be used. They are particularly applicable to discharging wounds of the axilla, popliteal space, and palm of the hand, because they fit snugly and tend to splint the part. They are also well suited to varicose ulcers and discharging sinuses of the abdomen. The ash pad is made in the following manner: The ash collected from the furnace is placed in a flour sifter and thoroughly sifted. It will be found to fall on a sheet of paper as a soft, brownish, floury powder. This is all the preparation necessary. A piece of old sheet or well washed linen is cut in rectangular shape and of any desired size. The square is placed on a table and a small pile of the ash is placed in the centre. The sheeting or linen is then folded over it, as in making a poultice. Such a pad can be made rapidly, and when examined will be found soft, compact, and absorbent. It can be nicely adjusted to any part of the body with adhesive plaster straps. After an ash pad has been applied to a discharging wound for some time it becomes moulded to the part, as the ash loses its powdery consistency owing to absorption. It has then the consistence of dough, and acts as a partial splint, being more comfortable than otherwise.

## MEDICAL RECORD.

March 14, 1906.

1. Some Observations on the Effects of Tobacco in Surgical Practice. By L. BOLTON BANGS.
2. Preliminary Report of a Case of Cerebrospinal Meningitis of Streptococcus Origin Apparently Cured by Subdural Injection of Antistreptococcus Serum. By GEORGE L. PEABODY.
3. Sæptal Hæmatoma and Abscess. By JAMES E. NEWCOMB.
4. Renal and Ureteral Calculi Complicating or Simulating Appendicitis. By JOHN F. ERDMANN.
5. Retrodeviation of the Uterus and Treatment by Shortening the Round and Sacrotuberine Ligaments. By C. F. KIVLIN.
6. Traumatic Rupture of the Spleen with Report of a Case. By V. E. WATKINS.
7. Relapsing Fever with a Report of Two Cases. By SAMUEL J. GOLDFARB.

1. **Some Observations on the Effect of Tobacco in Surgical Practice.**—Bangs cites some such cases and thinks that, as the heart has become accustomed to, and dependent upon, the tobacco, sudden withdrawal should not be counselled. These observations strengthen the opinion that the restlessness, depression of vital force, and melancholia of some of our ward patients may be due to the deprivation of their accustomed stimulant. Dr. Larabee, of Harvard University Medical School, says that emotional strain, overexercise, insufficient or improper food, and indulgence in alcohol will predispose to some of the ill effects of tobacco, and states that a series of cases of angina appeared on a French man of war where the men, debilitated by scurvy and poor food, smoked to excess in a small, close apartment. It is possible that some of these predisposing influences may, and they probably do, exist in many of our hospital patients, but nevertheless the relation of tobacco to the individual ought to be considered more than we are in the habit of doing.

3. **Sæptal Hæmatoma and Abscess.**—Newcomb, in speaking of the treatment of sæptal hæmatoma and abscess, says that it is simple in case of hæmatoma alone. The usual cold applications may be made over the nose and its interior kept clean. If the contents seem fluid they may be aspirated and firm bilateral pressure made by some form of tube or tampon, preferably the former. Serous cysts should be incised and their cavities scraped. The incision should be a generous one. In case of abscess the sooner and the more freely the incision is made, the less liability to destruction of cartilage and deformity. At times it is extremely difficult to keep up proper drainage. Strips of gauze or tubes inserted through the incision will not stay in place. Ernest Waggett has suggested the thrusting through the incision of a knotted loop of horsehair. A seton may also be employed. The abscess cavity should be thoroughly flushed with peroxide solution followed by some alkaline antiseptic, but it should never be packed. In some instances of pus accumulation he has opened the cavity with the galvanocautery. In case of multilocular abscess it is of value to rupture the mucosa against that of the opposite side, either protective being placed in contact with the mucosa. The cavity is thus obliterated by anastomosis.

4. **Renal and Ureteral Calculi Complicating or Simulating Appendicitis.**—Erdmann describes his mode of operation thus:—When, a great deal

the stone is in the ureter, it is a decidedly simple matter to approach it either by the transperitoneal route through a Deaver or Kammerer incision, removing the appendix, palpating the course of the ureter, and finding the location of the stone. Then by a narrow extraperitoneal dissection from the outer margin of the incision one rapidly reaches the site of the stone, the ureter and stone being held transperitoneally and pushing upwards. Then through the retroperitoneal dissection the ureter is incised over the stone, the stone expelled, and the ureteral wound sutured or not, a small drain put down to the trauma in the ureter. The peritonæum is then sutured and the muscles and skin sutured to the emergence of the drain. There is no necessity of suturing the wound in the ureter. The author prefers the transperitoneal localizing method, as it is rapid: one can hook the fingers under the ureter and push it up without contusing it, as is done with the usual instruments required in the retroperitoneal method. In the retroperitoneal method one must make a very long incision and dissect up a large amount of the pelvic and abdominal anatomy before arriving at the site of the stone. When the stone is situated high in the abdomen or is in the hilum of the kidney, the incision is either the oblique lumbar or the incision of Israel. One need not hesitate in either of these operations, provided the renal association is not ineffective, to explore the appendix through a nick in the peritonæum, and remove it, as it is readily found even in the usual incision of Edebohl for nephrorrhaphy.

6. **Traumatic Rupture of the Spleen, with Report of a Case.**—Watkins describes the symptoms as follows: They are essentially those of an abdominal injury associated with internal hæmorrhage. The shock is pronounced, as evidenced by the anxious facies, the pallor, feeble and rapid pulse, and collapse. Consciousness is usually retained in all abdominal injuries. The pain is severe and may be more pronounced in the splenic region. If the case is seen early, before the effusion of blood fills the peritoneal cavity, the dullness can be localized in the left flank, otherwise it will be general over the abdomen. An unusually pronounced contraction of all the abdominal muscles has been reported as a diagnostic sign, but it does not occur in all cases and cannot be considered pathognomonic. In fact, it may not be more marked than in other abdominal conditions. Vomiting may or may not occur. From this résumé of the symptoms it will be seen that they are essentially those of internal hæmorrhage, and the diagnosis is usually not made until after abdominal section. The symptoms are obscure so far as enabling us to distinguish whether the spleen or some other abdominal viscera is ruptured. However, there should be no difficulty in recognizing the existence of hæmorrhage into the abdominal cavity, and when this condition is recognized, abdominal section is indicated. The incision should be made over the region of greatest dullness, if this can be determined. It is more common to make a single cut in one flank than in the other, a valuable hint as to the nature of hæmorrhage has been obtained. Should the hæmorrhage be sufficiently severe to give peritonæal rigidity and tenderness in all regions the indication is to make the incision in the middle line.

The treatment is essentially surgical, the object being the control of hæmorrhage, and all authorities are agreed that this end is most certainly accomplished by splenectomy. The mortality following removal of the healthy spleen for rupture is about 40 per cent., whereas that of nonoperative treatment is probably 100 per cent. Ligation of the bleeding vessels has been recommended, but is invariably followed, in animal experiments, by necrosis. Control of the hæmorrhage by suture has been advised and has succeeded in some cases, but in the large majority the sutures have failed to control the hæmorrhage and the patients have died. Tamponade is certainly a quicker and better method than suture, according to the results thus far published, yet some authorities reject this treatment as suitable only when the tear is small, or in cases in which the condition of the patient necessitates a speedy ending of the operation, or in those in which extensive adhesions make the removal of the spleen too long an operation.

By M. WATSON.

1. **Multiple Serositis.**—White reports a case of this remarkable affection occurring in a woman, thirty-one years of age when she first came under observation, complaining of swelling of the abdomen, due to ascites, and for which she had then been tapped some thirty times. The first tapping took place in 1902. There was no disease of heart, lungs, or kidneys. She died in 1906, having been tapped in all nearly seventy times, and nearly two thousand pints of fluid withdrawn in all. This chronic affection of the various serous membranes has had many names given it—polyorrhomenitis, multiple serositis, polyserositis, progressive serositis, and Concato's disease. The peritonæum, pleuræ, and pericardium are chronically inflamed and thickened. The serous membrane may become centimetres thick; it has a dense opalescent appearance, and consists of several stratified layers. It can always be peeled off the subjacent organs. No case should be regarded as an example of multiple serositis unless, after careful examination, neither tubercle or growth can be discovered. The disease may occur at any age. It is equally common in men and women. There is often a history

of previous acute infectious disease which strongly suggests that the serositis is bacterial. Out of fourteen cases the peritonæum, pericardium, and both pleuræ were all affected in seven cases; one or more of these serous membranes, but not all, were affected in the remaining seven cases. Perihepatitis is always present, and perisplenitis nearly always. In the great majority of cases the disease begins in the peritonæum; in a few the pericardium is the first membrane involved; in these cases there is apt to be indurative mediastinitis, the lungs being bound in one mass to the pericardium, and there being no cirrhosis of the liver. The kidneys are often granular. The prognosis is very bad, but cases may last for years. The ascitic fluid contains a large amount of albumin. The histology of the thickened membrane clearly shows it to be inflammatory. Little can be done as regards treatment; diuretics hardly seem to restrain the accumulation of the fluid. The only thing seems to be to remove the fluid frequently.

2. **Antimony.**—Smith puts in a plea for antimony and potassium tartrate, a remedy of great value, which has been strangely neglected of late years. With our present views we should not prescribe the salts of antimony with any desire to produce a profound sedative effect upon the vascular and muscular systems, but should limit our efforts to obtaining free secretion from the mucous surfaces and the skin. For this purpose antimony remains preeminent, but it should always be prescribed in small doses given frequently, for it is only by this means that its full effect can be obtained without any danger of lowering the patient and giving rise to unwelcome signs of depression. In cases of bronchial catarrh and bronchitis there is no drug to take its place. Great severity in the attack is no bar to the use of the drug. In the early stage of bronchopneumonia in children it is of undoubted value, being most useful at the period when the consolidation is still in patches. Belladonna is also of value at the same period, and the two remedies may be combined. Laryngitis stridulus is another disease in which antimony is of great benefit; it should be given as wine of antimony in doses of 15 to 20 drops, so as to induce a slight feeling of nausea. Hot fomentations to the throat aid materially. Very small doses of antimony act as a gastric sedative, and are also of value in inflammatory conditions of the skin, especially in eczema. To its quality as a hepatic stimulant antimony owes its inclusion in "Plummer's pill," where it is combined with calomel and guaiaicum.

3. **Sudden Death.**—Westcott holds that in cases of sudden death, sixty per cent. are of cardiac, thirty per cent. of cerebral, and ten per cent. of pulmonary origin. Among the causes of cardiac syncope are hæmorrhage (external and internal), perforation of the bowel in typhoid fever, valvular disease of the heart, angina pectoris, rupture of the heart, sudden changes in pressure on the bloodvessels (as in paracentesis, etc.), severe burns, simple fatty degeneration of the heart muscle, etc. Mental impressions, sudden violent pain, sudden blows on the testis or epigastrium are also occasional causes of sudden death from cardiac syncope. As regards pulmonary causes of sudden death, the im-

portant ones are the arterial hæmorrhage of phthisis, diffuse pulmonary apoplexy, and complications of pleurisy. Asphyxia may also be due to œdema of the lungs, to pulmonary embolism, to overdense or overrarefied air, to illuminating gas poisoning, etc. Persons may die asphyxiated from hydrophobia, tetanus, and strychnine, or other poisoning. Sudden deaths accompanied by coma are mostly due to diseases of the brain or to apoplexy. Kidney disease has no fourth type of death to supplement syncope, asphyxia, and coma. Sudden death in convulsions may occur in epilepsy.

**5. Cachectic Striæ Atrophicæ.**—Rolleston reports the case of a boy, aged sixteen years, suffering from malignant disease, in which extraordinarily well marked lineæ atrophicæ began to appear on the back about ten days before death. The factors concerned in their production were (1) malnutrition, due to cachexia, which disposed the dermis to rupture on slight provocation; and (2) traction exerted on the dermis in the process of turning the patient in bed. Osler divides lineæ albicantes into three groups: (1) Those due to distension—the ordinary lineæ gravidarum; (2) the post-febrile, especially those occurring after typhoid and scarlet fever; and (3) the idiopathic form.

**7. Scarlatina Without Eruption.**—Thornton states that in a community affected with scarlatina, in addition to those showing definite signs of the disease, there are others affected by the poison to a minor extent, as shown simply by an elevation of temperature. It might be a useful precaution to take the temperature of contacts, with a view to keeping under special observation those who, while otherwise quite well, show a moderate degree of fever.

9. The Case of Anthrax. By J. S. GARDNER.
10. Tausim Method for the Cure of Cancer of the Breast. By F. FLETCHER.

**1. Colon Infection of the Urinary Tract.**—Dunnigan states that in most acute infections of the urinary tract due to the colon bacillus, the onset is sudden, a chill being the first indication. The fever may reach 104° to 105° F. There is frequency of micturition, with pain, and the passage of small quantities. Nausea and vomiting are often present. Tenderness of both kidneys may be detected, usually much more marked on one side. In some cases the spleen is distinctly enlarged, which, with the fever, may lead to a diagnosis of typhoid fever. The

urine is acid and turbid from the presence of bacilli. In the chronic cases the symptoms may vary from a few apparently unimportant facts to a condition of considerable severity. In women the bacillus coli may multiply in the urine, causing bacilluria and sometimes pyuria, without causing any symptoms pointing to an infection of the urinary tract. When fever occurs in such cases the diagnosis is apt to be malaria, tuberculosis, or influenza. In men such cases are less common. So called gouty urethritis may be due to an infection of the urine and urethral mucous membrane by the bacillus coli. Incontinence of urine in children is sometimes associated with the presence of bacilli in the urine. In by far the larger number of cases the urine is acid. The presence of colon bacilli in sufficiently large numbers to give rise to turbidity causes a characteristic "shimmering" appearance. A nucleoprotein substance is present in the urine in most cases, usually albumin. Casts do not occur in uncomplicated cases. That the colon bacillus is often present in apparently normal urine is shown by its being found in the urine of ten out of forty-five cases of pregnancy, in four out of twenty cases of peritonitis, and in five out of fourteen cases of prostatic enlargement. These facts serve to explain how infection of the urinary tract may occur. There is no evidence that the urine in these cases contains either an excess or a deficiency in opsonins—the substances which render the bacilli more or less susceptible to phagocytosis. That there is little systemic immunity is shown by the fact that it is extremely rare to obtain a well marked agglutination reaction of the colon bacillus with sera obtained from all classes of cases of bacillus coli infection. Indeed, in most instances patients suffering from an infection of the urinary tract due to the bacillus coli, whether it is acute or chronic, show a low opsonic and phagocytic index. The prognosis of the acute cases is usually excellent, as long as the infection remains uncomplicated. As regards treatment, medicinal treatment is of little, if any, avail. Urotropin, which produces such wonderful results in other classes of cases, is useless here. Cure, when it occurs, is usually spontaneous. Good results have, however, been obtained in the acute cases with anti-colon bacillus serum. In five out of twelve cases the results were rapid and permanent, while in four more considerable benefit ensued. In the subacute cases the serum is also useful, but not as much so as in the acute cases. Twenty-five cubic centimetres of the serum should be given each day for three days. Calcium lactate in doses of twenty grains three times a day will diminish the objectionable effects of the serum, such as joint pains and rashes. In chronic cases the Wright treatment by means of vaccines should be tried. Unfortunately the cases due to the colon bacillus do not give as satisfactory results as are obtained in the case of staphylococcus aureus and albus.

**3. 4. 5. 6. Delayed Chloroform Poisoning.**—Thorp reports a fatal case of delayed chloroform poisoning or renal intoxication, occurring in a boy aged three years and ten months. The child was anaesthetized upon ten phlebotomies and was given chloroform for seven minutes, about two drachms being used. Thirteen hours later symptoms of renal intoxication set in, and the child died about twenty-four

hours later. No antiseptics were used such as might contribute to the cause of death. Telford reports three cases, two in boys, aged two and a half and one and three-quarters years, respectively, and in a girl aged eight years. The operations were for tuberculous epididymitis, right inguinal hernia, and double genu valgum. The younger boy recovered. We do not seem any nearer to a solution of these cases—why certain children will develop a state of acid intoxication after the administration of an anæsthetic and die with fatty degeneration of the liver, kidneys, and heart. The condition is not rare, as the writer has seen four deaths out of 1,500 cases of chloroform anæsthesia in a children's hospital. It is not sufficient to seek for a cause in a tabulated list of the diseases for which the children are treated. There must be in such children some common predisposing cause which we are not yet able to recognize. The fatty changes which are found on post mortem examination are probably due directly to the anæsthetic and do not represent an antecedent condition. The naked eye change in such an organ is merely the total of its cellular changes, and such changes may well happen in the last two or three days of life. The writer has never seen the fatty kidneys present in these cases in children dead from other causes, and holds that it is in the highest degree unlikely that such grave alterations could exist in the kidneys without yielding obvious clinical signs of their presence. In a previous paper he has referred to the dangers of anæsthetics in children suffering from rickets. Rickets in an active condition was present in each of the three cases here reported. He has not been able to satisfy himself that the treatment of cases of delayed chloroform poisoning by alkalis or by intravenous saline infusion is of the least value. Bride reports two cases, both occurring in girls, aged three years and fourteen years, respectively, the latter case recovering. The operations were for congenital talipes equino-varus, and for genu valgum. The points of interest were: 1. The absence of any possibility of poisoning by antiseptics. 2. In both cases the operation wounds were surgically clean. 3. Stress has been laid on the fact that codliver oil has been given in such cases. One of the patients had never taken it, and the other only at intervals. 4. Both children were markedly rickety. Wilson reports a fatal case in a girl aged six and a half years, who was operated on for tuberculous disease of the right hip. While acetone was early present on the breath, it did not appear in the urine until three days later. A history of cyclic vomiting prior to admission supports the view that cases subject to that affection are also liable to post-anæsthetic poisoning or fatty acid intoxication. All that can be said at present is that a general anæsthetic must interfere with fat metabolism in such a way that complete oxidation of fat does not take place and the intermediate products of fat metabolism, betaoxybutyric acid and diacetic acid, pass into the circulation and give rise to the symptoms of fatty acid intoxication. Fatty liver is a constant phenomenon in all post mortems on these cases. Some connection exists between this and the symptoms, but the exact relationship is obscure.

10. Tausini's Method in Cancer of the Breast.—Purpura states that Tausini's method for the cure

of cancer of the breast consists, first, in removing all the skin of the breast, compensating the loss of substance by the provision of a perfectly nourished flap, which makes it possible to approximate the skin edges in the region whence it is taken by a lineal suture; the flap is formed from skin rarely invaded by cancer, and with its large pedicle abundantly covers the loss of skin of the axilla. The flap allows the arms to move freely.

#### LA PRESSE MEDICALE

The Diatheses. The Personal Factor in Disease,  
By SIR DYCE DUCKWORTH.

**The Personal Factor in Disease.**—Duckworth protests against the tendency of modern times to neglect the personal factor, which the clinician must ever face in the treatment of disease. He believes the present tendency to adopt new revelations and to ignore or condemn the old to be a dangerous error, and that the diatheses, which cannot be studied in the laboratory, and cannot be attributed to the presence of infectious microbes, deserve careful study and attention. He discusses particularly subjects of arthritic, scrofulous, and nervous diatheses.

February 22, 1908.

1. The Action of Glycolytic Ferments Injected into Man,  
By R. ODIER.
2. Therapeutical Action of Radium in Cutaneous Tuberculosis,  
By LOUIS WICKHAM and DEGRAIS.
3. Poliomyelitis and Ventral Pseudohernias,  
By R. ROMME.

1. **The Action of Glycolytic Ferments Injected into Man.**—Odier endeavors to make clear the difference in the effect produced by the injection of trypsin and of the glycolytic ferments in the treatment of cancer. Trypsin is injected in the vicinity of the tumor in order to produce a local solvent, digestive, or destructive action upon it. The injection of the glycolytic ferments, on the contrary, produces a general effect wherever in the organism may be the point of injection and wherever may be the seat of the tumor. He speaks highly of the results obtained in cases of cancer by the injection of these ferments, and quotes a case in point. He describes more than one way in which these ferments may be prepared.

2. **Therapeutical Action of Radium in Cutaneous Tuberculosis.**—Wickham and Degrais speak of the effects produced by radium on several forms of tuberculous skin disease, and conclude that, in their opinion, radium can render good service in every form of cutaneous tuberculosis, and that it deserves a place in the treatment of granulations, tuberculous ulcerations, lupus of the conjunctiva, of the vicious cicatrices which follow lupus erythematosus.

February 26, 1908

1. Removal of the Thyroid Gland in Exophthalmic Goitre,  
By PROFESSOR GARRÉ.
2. The Transplantation en Masse of the Two Kidneys,  
By J. P. LANGLOIS.

1. **Removal of the Thyroid Gland in Exophthalmic Goitre.**—Garré reports that he has operated in thirty-five cases of exophthalmic goitre, five men and thirty women. Partial excision of the thyroid gland was performed in thirty, ligation of

vessels in eight, resection of the sympathetic with enucleation of the intraglandular nodules in two. In every case the thyroid was very vascular and the vessels very friable; the veins in particular had extremely thin walls. Almost all the operations were performed under ether; in a few cases under local anæsthesia. The immediate results were invariably a diminution in the frequency of the pulse and an improvement in the general feeling of the patients. The exophthalmos was little influenced. The results after five years are thus given: The exophthalmos had disappeared in a third of the cases; in a quarter it persisted in the same degree as before operation; in the balance it was present to some degree. The tachycardia persisted without modification in four cases. In two thirds of the patients the pulse was maintained below 92; in the remaining third it did not descend below 100. The nervous troubles persisted in two thirds of the cases, and traces were present in the other third. The general condition was said to be excellent in fifty per cent. of the cases; in some the weight had greatly increased. So large a percentage of success and such a small mortality as attends the operation seems to the author to urge the adoption of the surgical treatment of this disease.

3. **Transplantation en Masse of the Two Kidneys.**—Langlois practically gives a translation of Carrel's article Transplantation in Mass of the Kidneys in *The Journal of Experimental Medicine*, January, 1908. That author successfully transplanted the kidneys from one cat to another.

The Reality and the Mechanism of the True Reduplication of the First Sound of the Heart.

By Professor L. BARD.

### Reduplication of the First Sound of the Heart.

—Bard reports a case of reduplication of the first sound of the heart met with in a man, twenty-five years of age, suffering from stenosis of the pulmonary artery and tuberculosis of the apex of the left lung, who died of tuberculous meningitis. These diagnoses were confirmed by autopsy, and from the findings at autopsy Bard works out the mechanism by which the reduplication of the first sound of the heart was produced.

### 1. Hypertrophy and Organ Correlation.—

Rösse points out that there are different forms of hypertrophy that are induced by different forces. First, there is such hypertrophy as the increase in size of the milk glands during pregnancy induced by a chemical stimulant. Such may also be the explanation of hypertrophies which are of correlative origin and produce a diffuse enlargement of an organ, such as the hypertrophy of the thymus. But local hypertrophies of certain parts of organs or of the vessels cannot be explained in this way. The common factor for all kinds of hypertrophy is to be found in the mechanical and chemical action of hyperæmia in strongly working tissue and the regeneration in excess after replacement of the used tissue. Only one form does not fall under this law, the congenital hypertrophy of organs and parts of organs through excessive formation. While all other forms of hypertrophy originate functionally from the work of the organ and are in a sense correlative, this form is a malformation which occupies the border land between hypertrophy and tumor.

5. **Rheumatismus Tuberculosis.**—Esau reports a case met with in a child six and a half years old, in which acute and subacute attacks of pain followed each other in both knees and ankles, the right hip joint, and the cervical segment of the vertebral column. From time to time there was a high fever, and the general condition became markedly impaired as these attacks went on. Part of the joints showed a tendency to great contracture in flexed positions, and under correcting appliances the disease healed partly in the form of a firm, fibrous ankylosis, the knee, partly in perfect restoration of the functions of the joints, in the ankles and the vertebrae, and in a bony ankylosis in the hip joint. The author believes this to have been a case of tuberculous rheumatism, although he cannot offer further absolute proof of its tuberculous nature. He quotes freely from the writings of Poncet and Leriche, giving their description of this disease and their belief, founded on their investigations, that it is the result of the action of the tuberculous toxine. The diagnosis is difficult, the prognosis not very good. The most favorable form of treatment seems to be that with hyperæmia, particularly that produced by a large suction apparatus.

7. **Breech Presentation at the End of Pregnancy in a Uterus Bicornis.**—Jacoby reports a case of this nature, the second child of the mother, and remarks that the plural occurrence of uterine bicornis is very rare.

8. **Punctured Wound of the Abdomen.**—Hartleb reports a case in which a boy, seven years of age, was stabbed in the abdomen with a table knife, and, under observation, exhibited some fever with normal temperature, pulse 104, no tenderness, and no positive indications that the intestine had been injured. Some hours later the appearance of peritonism was taken to indicate that the intestine had been injured, and laparotomy was performed six or six hours after the receipt of the wound, and

the intestine was found to have been cut in two places. This case shows that it is not always easy to distinguish between those wounds of the abdomen that demand surgical intervention and those which do not.

**II. Comparative Valuation of the Tuberculin Reactions in Childhood.**—Reuschel presents the following summary of his long article: 1. We have in the tuberculin reactions a means which points out to us any form of tuberculosis, active, inactive, or even healed, because, generally speaking, the reactions are produced by antibodies, which, so far as our present knowledge goes, are produced only after the engrafting of tuberculosis. 2. Pirquet's cutaneous reaction is handy and deserves to be used in practice. The positive result always shows a tuberculous infection; the negative is not as certain. 3. A good method of retesting when the Pirquet reaction is doubtful is the injection for observation of Eschrich's puncture reaction in the way recommended. At the same time this calls forth a desirable sensibility in inactive tuberculosis. 4. These two methods should not be looked upon as rivals of the older Koch's method, but the three should be considered supplements each of the other, because there are cases in which the calling forth of a local reaction must be aimed at. 5. It still remains to be determined whether the sensibility mentioned, which is an indubitable result, demonstrates antibodies to the tubercle bacilli material, or, what is very improbable, to the albuminous bodies of the bouillon.

#### ANNALS OF SURGERY.

March, 1908.

1. Tracheobronchoscopy, By C. JACKSON.
2. Trichinous Infection of a Carcinoma of the Lip, By E. A. BÄHLER.
3. Ludwig's Angina, By T. T. THOMAS.
4. Studies in Technique of Cancer of the Breast Operation, By R. H. M. DAWBARN.
5. Rupture of the Lung Without Costal Injury, By R. G. LE CONTE.
6. Acute Dilatation of the Stomach and Arterioesenteric Ileus, By W. B. LAFFER.
7. Unilateral Renal Hematuria Due to Pyelitis Cystica, By I. S. HAYNES.

1. **Tracheobronchoscopy.**—Jackson states that upper bronchoscopy by means of the slide speculum is usually easy under general anesthesia. The bronchoscope is inserted at the first inspiratory movement without difficulty and without injury to the larynx. The operation is more difficult in most cases, under local anesthesia, the resistance and rigidity of the muscles being such that the exposure of the laryngeal aperture for the insertion of the bronchoscope is not easy. This is especially the case in presence of the results of inflammatory action in the trachea and larynx, whether recent or remote. With the author's instrument no gag is necessary until the bronchoscope has passed the glottis. With this instrument it is not necessary to wait for an inspiratory movement or for the subsidence of the glottic spasm. Neither is it necessary to expose the anterior commissure, as its point can be started between the posterior ends of the vocal cords. The mouth of the tube will not catch over the arytenoids, while the point of the slanting extremity can be used as a retractor in the bronchi. The author has performed seventeen tracheobronchoscopies for foreign bodies below the larynx, in fourteen of which the body was removed.

3. **Ludwig's Angina.**—Thomas defines this as a rapidly spreading cellulitis beginning in the region of the submaxillary gland and extending to the floor of the mouth and pharynx. It may originate from a carious tooth, a tonsillitis, or an ulcer in the mouth. The infecting organism is the streptococcus, either alone or combined with staphylococcus, pneumococcus, or bacillus of malignant oedema. Death usually results from invasion of the larynx, the lungs being frequently involved also. The path of invasion is the opening in the muscular buccopharyngeal wall through which the submaxillary gland projects into the floor of the mouth. If the phlegmonous process begins in the pharynx or larynx, the danger is very great, as the tissues cannot be properly inspected, disinfected, and incised. Modern surgical treatment has somewhat reduced the extreme virulence of the septic phenomena. The most favorable incision is over the submaxillary triangle and parallel with the lower border of the jaw. If this does not reveal the abscess, the mylohyoid muscles must be divided and the sublingual tissues exposed. Local anesthesia is preferable when performing the operation.

4. **Studies in Technique of Cancer of the Breast Operation.**—Dawbarn thinks the great number of relapses after cancer operations signifies that further study is to be encouraged. He urges caution in operating when the diagnosis of cancer is not absolutely determined, and narrates a case in which he performed a radical operation only to find that the lesion was a thick walled abscess. He also recommends the procedure of Gerster, who attacks the armpit first and the breast last. By this means the lymphatic communication with the body is severed at the very beginning of the operation and the danger of squeezing infective material into the lymph stream at least lessened. It is also a means of lessening the hæmorrhage. An advantage in subsequent use of the arm will be gained by anastomosing a small segment of the deltoid with the stump of the pectoralis major. Finally he recommends the use of a triangular splint at the patient's side, in abduction, to favor the subsequent use of the hand in the necessary movements to raise it above the head.

### Proceedings of Societies.

#### MEDICAL SOCIETY OF THE STATE OF NEW YORK.

One Hundred and Second Annual Meeting, held at Albany,  
January 27, 28, 29 and 30, 1908.

The President, Dr. FREDERIC C. CURTIS, of Albany, in the  
Chair.

(Continued from page 558.)

**Diseases of the Pancreas.**—This subject was presented in a paper by Dr. WILLIAM J. MAYO, of Rochester, Minn. He referred to the pancreas as the great abdominal salivary gland with but a single defect, that being the association of its excretory duct with that of the liver. In 6.1 per cent. of all biliary operations the pancreas was involved, and 81 per cent. of cases of pancreatitis were due to gallstone disease. The secretion of pancreatic juice was

due to the presence of chyme in the small intestine, stimulating its mucous membrane; fluids were absorbed from the large intestine and solids from the small; thus we ate with the small and drank with the large intestine.

Pancreatitis was always due to infection or to chemical irritation, as from the action of bile which found its way up the pancreatic duct after an obstruction at the papilla of Vater. The weight of this last cause was materially increased by the statement that 62 per cent. of cases of pancreatitis were associated with jaundice of an obstructive nature. But, on the other hand, a large percentage of the simple catarrhal jaundice cases were due to an inflammation of the pancreas similar to mumps.

Pancreatitis, if acute, was said to be usually associated with hæmorrhage; if more chronic in nature it was apt to be purulent. The fat necrosis, he believed, was not due to the action of normal pancreatic juice, but of that which had been called forth by bile or duodenal secretion. Furthermore, he did not believe this fat necrosis to be so fatal as was ordinarily supposed.

This disease, he declared, usually attacked people of about middle life, rather obese, and often patients who had been intemperate in the use of alcohol. The symptoms were seen to come on suddenly with nausea, vomiting, etc., resembling intestinal obstruction high up.

He classified pancreatitis as of two varieties—the interlobular, often associated with gallstones and to the "feel" resembling a malignant growth, and the interacinous, often associated with glycosuria, in which the pancreas was large and smooth. The first type might go on to the development of the second, and the disease extend over a period of years with almost continued jaundice, emaciation, and large pasty stools containing fat or undigested muscle fibres.

He advised clearing out all calculi at an operation and freeing the hepatic ducts thoroughly by the passage of a large probe through the common duct.

**Duodenal and Gastric Ulcers** were the subject of a paper by Dr. J. J. OEHNSNER. He believed the joint consideration of duodenal and gastric ulcer to be proper, inasmuch as they were developed from the same embryological structure, the foregut, *in utero*, and often intimately associated pathologically in the adult. The duodenum was shown to be an extension of the stomach, furthering the processes of digestion, but in an alkaline medium.

He believed the ætiology of gastric ulcer to be: 1. Injury from within. The pyloric end of the stomach had the hardest work to perform, and injuries were most apt to occur there. 2. The lack of production of certain antibodies whose function it was to prevent the digestion of the mucous membrane by the gastric juice. 3. Anæmia. Duodenal ulcer was caused by extension from an ulcer of the stomach by the irritating action of the acid gastric juice upon the mucous membrane of the duodenum, burns of the skin, or by thrombi of the bloodvessels of the duodenum.

He referred to the sphincter muscle in the duodenum, from 7 to 10 cm. below the entrance of the common duct, and to the frequency of relapses after apparent cure, but declared that, if the diet then

could be restored to the normal without the intervention of surgery, it was far better for the patient. He emphasized the facts that even after a so called cure the patients must be careful as to their diet and that, of the patients operated upon, only one third were comfortable unless they were careful in this respect later. The most serious complications he thought to be perforation, hæmorrhage, emaciation, adhesions, and implantation of malignancy. While some cases responded better to surgical treatment and others to medicinal, it was not possible to distinguish between the two types until medicinal treatment had been instituted, and he believed all cases surgical that were not amenable to medicinal treatment.

The pain found in this disease he had observed to come on after eating, especially if the ulcer was at the pylorus, and it might be referred to the middle of the sternum or to the back. In gallstones the pain referred to the back was at a lower level. In duodenal ulcer the pain might come on some little time after taking food or even before, from the escape of acid gastric juice into the intestine due to a relaxed pylorus. Blood in the stools would often help in the diagnosis. The large amount of mucus was believed to act as a protecting coat against the action of the irritating gastric juice, but this would also cover the food ingested and render its digestion slower.

In the early stages of pyloric stenosis the musculature of the stomach was seen to undergo hypertrophy to force the food through the contracted orifice, but this musculature weakened after a time and dilatation followed. In the meantime the ulcer might have crowded a bloodvessel and a hæmorrhage occur, and perforation was not an infrequent complication.

After dilatation had occurred there was usually residual food in the stomach, and even when fresh and wholesome food was ingested it would soon be contaminated and decompose: hence the indication for frequent gastric lavage.

The objects of the surgical treatment were drainage and rest, and the results would vary with the skill of the operator and the strict adherence to good hygiene and dietetics afterward. The directions given were: Inflict as little injury upon the tissues as possible. Expose the other intraabdominal organs as little as possible. Have the patient assume the sitting posture as soon as possible after the operation. The direction of the sutures should be such that the contraction of a subsequent scar will not cause an obstruction. Excise any neighboring lymphatics in case of complicating malignancy. Choose the lowest point for anastomosis. Have no tension upon the sutures. Except in complete obstruction, always preserve the coronary artery. In acute dilatation following an operation, introduce a stomach tube and wash out the stomach with about half a pint of water. In an operative case the simplest technique without any unnecessary mechanical transportation of the patient's habits and diet as long as possible afterward.

#### The Surgery of the Liver and Gallbladder.

This paper was read by Dr. J. C. MASON. First, he begged permission to ask the question if hepatitis of the liver was a surgical disease. He said that

nonoperative cases of liver disease often showed a marked specific history. Gummata were the most common syphilitic lesions of the liver; they might vary in size from that of a pinhead to that of an egg. They might undergo fatty degeneration, be absorbed, and only a scar remain; they might calcify, or they might become infected and form abscesses. He declared that the liver was often affected, but gave rise to no symptoms whatever.

When the peritonæum was involved, pain, limited respiration, ascites, loss of weight, evidence of infection, and jaundice might be found, though the last symptom was not common. The most common site for syphilitic lesions was seen to be near the suspensory ligament. Thus the resemblance to malignant disease could be readily seen. Diarrhoea had been observed by some, but in the writer's experience constipation was the rule. He stated that a tumor might often be felt, and any associated pain was frequently relieved by vomiting, and finally pointed out the conditions which might resemble the present lesion, such as cirrhosis, abdominal tumor, functional dyspepsia, malignancy, cholecystitis, biliary colic, and chronic intestinal obstruction.

Another question that he wished to ask was as to the proper treatment that might have been given to patients that died a few hours or days after an operation, from complete suppression of the liver function. He cited such cases and said that the symptoms usually began much like those of septicæmia or severe hæmorrhage.

He believed that surgeons were coming more and more to consider the question of the preservation of the gallbladder in an operation, because at any subsequent operation which might be necessary the dangers were materially increased by absence of the gallbladder.

**Nonparasitic Cysts of the Liver and Congenital Cystic Liver.**—In this paper Dr. W. G. MACDONALD, of Albany, spoke of the low mortality associated with the abdominal surgery of to-day, and stated that when death did occur it was usually the result of an incorrect diagnosis or the exploratory incision. The best surgical training afforded no adequate preparation for the unexpected in surgery. A false diagnosis destroyed the continuity of an operation, hasty preparation had to be made for a new operation with the patient under the anæsthetic, and the surgeon wandered aimlessly about until compelled to desist, either from hæmorrhage or from some other complication, or went ahead with an original procedure upon general surgical principles. He referred to the many valuable aids in diagnosis that modern medicine afforded, such as examination of the gastric contents, physiological chemistry, the Röntgen ray, the gastroscope, etc.

He presented the histories of three cases of cystic liver. In the first the patient had been treated for ascites, as the abdomen was full of fluid. Under local anæsthesia he opened the peritoneal cavity and evacuated about eight quarts of a clear fluid. Upon the lower surface of the liver he then found a fluctuating tumor. He aspirated it and drew off fluid (about 500 c.c.) of the consistence of glycerin. The ascites did not reappear for some

The second case was one of cyst of the liver. In this case the incision was made in the usual situation for a gallstone operation, and the cyst attached to the abdominal wound and drained. Before the operation the diagnosis had been made of a distended gallbladder, but the gallbladder was found to be normal and the tumor to be a large liver cyst filled with about 6,500 c.c. of clear mucin. It was drained for about three weeks and the patient made an uneventful recovery.

The third case also simulated gallbladder disease. Drainage was used, and recovery followed.

The difficulty in the diagnosis of this condition was pointed out, and the possible reason given was its rarity. The object of this paper was to show that in tumors of the upper abdomen, nonparasitic cysts must be kept in mind. In the three cases above cited the pathological report showed these cysts to be nonparasitic in origin.

**Gastric Neuroses.**—In this paper Dr. D. D. ROBERTS began by saying that, the treatment and cure of disease being the primary end of all the branches of medicine, a study and classification of functional disturbances was also desirable. He believed neuroses gave rise to more symptoms than actual diseases themselves, and the essential question was not *what* function was abnormal, but *why*. He referred to the two schools in the treatment of gastric neuroses, one advocating a meat diet and the other vegetables. Some patients were unduly conscious of any pathological condition, and hysteria varied according to the degree of suggestibility. When the physician failed to spend time in investigating and studying a patient's environment he sent him to seek relief in all sorts of creeds and therapy. The function of the normal and abnormal stomach had been studied well, but in treating it the average practitioner seemed to consider it by itself and not as but a part of an intricate mechanism, the disturbance of any element of which might cause its derangement.

**The Diagnosis and Treatment of Gastric Ulcer.**—Dr. D. ROCHESTER, in this paper, reported a case the clinical symptoms of which were characteristic of gastric ulcer. A hæmorrhage occurred, and the case was treated medically. A few days later another profuse hæmorrhage came on. As soon as the patient rallied sufficiently an operation was performed by Dr. Roswell Park. No ulcer was found on the anterior surface of the stomach. The stomach wall was opened and inspected from within, but still no ulcer could be demonstrated. Since then he had been more skeptical as to the advisability of an operation in gastric ulcer, resorting to it only when there was evidence of perforation. In cases similar to the one cited above he believed the cause to be reflex or some nervous taint.

The symptoms were epigastric pain increased by food and often referred to the back; however, food might relieve the pain for a time. A definite tender spot might be elicited, and sometimes the area of hepatic dulness was decreased. The patients might show a tendency to anæmia, due probably in part to loss of blood from hæmorrhage, which might often be demonstrated in the stools.

The treatment could be divided into three different stages—the treatment of hæmorrhage, the treatment of the patient to cure the ulcer, and treat-

ment of perforation. For the hæmorrhage he advised physical and mental rest on the part of the patient and functional rest for the stomach. This could be best accomplished by a full dose of morphine and atropine, cold to the epigastrium, and possibly a 1 to 1,000 solution of adrenalin. Withhold everything by the mouth but possibly cracked ice. The subgallate of bismuth in milk of magnesia might be given. Food by the mouth was believed to be harmful at any time during the first forty-eight or seventy-two hours, and even by the rectum for the first twenty-four, because it would cause the secretion of gastric juice.

In the attempt at curative treatment he advised the physician to examine carefully the eyes, ears, pelvic organs, urine, etc., and to correct any abnormality found. Constipation and colonic toxæmia must be treated if found to exist. Then rest, graded exercise, and hydrotherapy were advised. As to the direct medication of the stomach, he ordered the exclusion of all coarse meats, liquors, strong tea, coffee, and fruits that did not agree with the patient. Carbonized waters, malted milk, chicken, fresh fish, rice, sago, and tapioca (the last named to be taken with no salt and but little sugar). Three or four hours after each meal he advised drinking about half a pint of diluted milk. He recommended slow eating, thorough mastication, and mental rest at meals.

Good results could be obtained from strontium bromide, sodium bicarbonate, charcoal, and bismuth subcarbonate, all suspended in milk of magnesia. This treatment must be continued for a long time, and in all cases he advised a thorough search for and thorough correction of any reflex nervous disturbance.

**The Modern Conception Regarding Chemical Regulation of Function.**—Dr. GRAHAM LUSK observed in this paper that there was much in the nervous system below the threshold of consciousness. The cause of death in animals after the excision of the adrenals was the removal of their internal secretion from the system and not the shock incident to the operation. The active principle of this secretion was not a ferment, because it could not be heated to boiling without destroying its activity. In tuberculosis of the adrenals, the thymus, spleen, etc., might become secondarily enlarged, thus demonstrating a very complicated and involved problem in physiology at present unexplainable. He referred to the great number and general uselessness of the theories brought forward by fanciful observers anxious of recognition.

He stated that solid substances introduced into the time which had been cut off from its nerve supply would still cause secretion due to the mechanical stimulation of the pyloric receptors. When food was taken into the mouth there were impulses which traveled along the vagi and thus produced a reflex secretion. A secondary secretion might take place even if both vagi were cut. If partly digested food was placed in the stomach

He believed that the secretion of the gastric juice depended upon a substance absorbed from the secretum of the pylorus and taken into the blood. This stimulated the gastric secretion. Hydrochloric acid was stimulating to the duodenal mucosa, causing a secretion of the pancreatic juice

and he cited experimental work of Popeelski proving that fact.

As to the formation of the pancreatic juice, the acid gastric juice from the stomach activated a prosecretin there. This prosecretin was absorbed into the blood and then caused the secretion of pancreatic juice. Nerve reflexes were not necessary, simply the chemical stimulant being absorbed into the blood stream. If portal blood was diverted from the liver, the symptoms of toxæmia resulted, and this was shown to be due to the fact that certain toxins and deleterious substances were rendered innocuous in the liver.

Experiments had shown that if an extract was made of a rabbit's foetus and injected into the blood of a virgin rabbit, the mammae would develop. Also in the human species, it was pointed out, if one kidney was extirpated, the blood pressure was raised and hypertrophy of the left ventricle occurred, which went to prove that ordinarily certain substances were excreted by the kidneys in a definite amount; one kidney could not excrete as well as two, so part of these substances were retained, and by their pressure caused a rise in blood pressure.

In fevers, the xanthine bases were present in amounts corresponding to the height of the fever; therefore the administration of xanthine free milk in febrile patients was declared to have scientific justification.

**The Effect of Alcohol upon Secretions.**—Dr. H. C. JACKSON, in this paper, said that no other substance taken into the human economy had such a variable effect upon digestion. Its effects were divided into that upon the activity of the hydrochloric acid and pepsin, that upon the amount of secretion, and that upon the motion of the stomach. Inasmuch as it was rapidly absorbed from the stomach, its influence was soon removed from the site of activity. In the beaker, alcohol was shown to retard digestion in a direct proportion to the amount present. In the stomach the malt liquors in small amount had no influence upon digestion, but in large amount they retarded it. With liquors containing less than ten per cent. of alcohol its effect was declared to depend upon the solids in solution and not upon the alcohol present. Strong alcohol rendered the pepsin less active and might even coagulate albumin. Experiments upon animals were cited in which the food was introduced through a fistula without the knowledge of the animal, in order to obviate the psychic effect. In the first stage, while alcohol was present in the stomach, pepsin was diminished. In the second stage, when the alcohol had been absorbed, the hydrochloric acid was increased. In these experiments alcohol had the same effect as twenty to thirty minutes; the short time that spirit of less than ten per cent. strength remained in the stomach did not materially affect digestion. If the strength was over ten per cent. it remained in the stomach for the same time as was occupied.

Then the process was shown to be little affected or possibly slightly improved by a single dose of a solution of less than ten per cent. strength. In strength greater than ten per cent. the digestion was retarded, pepsin decreased, mucus increased, and motility lessened. The secondary effect of dry wines was stated to be so far from inhibitory as dry liquors, as the action of their bases with the food, and

so they exerted a marked inhibitory effect. Alcohol was seen to affect the secretory mechanism of the pancreas by being absorbed into the blood, and by means of the circulation stimulating the secretory centres in the medulla. The digestion of fat by lipase was enhanced by alcohol given in any strength. The pathological chemistry of the liver had received much attention, but up to the present time was negative as to results. Alcohol appeared in the bile much sooner than in the urine. Alcohol in the stomach would increase the formation of bile from 50 to 360 per cent. The prolonged irritation of the alcohol exerted in the liver was probably the cause of cirrhosis. The conclusions were that a single dose of an alcoholic beverage of less than ten per cent. strength might benefit the process, but that additional doses were wasteful.

Dr. STOCKTON, of Buffalo, believed that there could only be assent to the conclusions set forth in Dr. Mayo's paper as to the association of pancreatic and biliary disease. He believed that chronic pancreatitis was a more common disorder than was usually supposed, even with no biliary involvement.

He considered the paper of Dr. Ochsner important because it took up the treatment of gastric ulcer both before and after an operation.

As to Dr. Roberts's paper, he believed it of greatest importance that these nervous diseases of the stomach should be well studied, inasmuch as at present they were but poorly understood. He deplored the tendency of the average physician to give so little attention to disturbances the basis of which was known to be functional.

(To be continued.)

### Book Notices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

*Cancer of the Womb.* Its Symptoms, Diagnosis, Prognosis, and Treatment. By FREDERICK JOHN McCANN, M. D. (Edin.), F. R. C. S. (Eng.), M. R. C. P. (Lond.), Physician to In-Patients, Samaritan Free Hospital for Women, London, etc. London: Henry Frowde (Oxford University Press) and Hodder & Stoughton. Pp. x-172.

In spite of the small array of its numbered pages this is a fairly thick book, for there are forty-six full page inset plates in addition to a colored frontispiece, and we may remark at the outset that the pictures are excellent.

The volume opens with an Anatomical Introduction, rather unnecessary, we think, though very well worked up in the main. An exception to the general clearness of the author's style, as it seems to us, is this sentence: "The ringlike attachment of the vagina is very oblique, having a much lower level in front than behind, and thus the posterior vaginal wall is longer than the anterior."

A general consideration of the subject of malignant disease comes next. As regards the etiology, "the trend of modern opinion," says the author, "is against the parasitic theory," and in support of the latter he quotes from the *Third Annual Report of the Harvard Cancer Commission*, which, he says, "tends to the demolition of

the parasitic hypothesis." He thinks that heredity has a certain influence, but regards the question as not yet decided.

As to the diagnosis of uterine cancer, apart from the local signs, the author remarks that wasting is frequently absent. The one symptom of greatest significance is hæmorrhage, though it is not usually so severe as the bleeding produced by fibroids. "Any loss of blood after the menopause," he says, "is a sign of the greatest importance, and in every case a thorough investigation of the condition of the pelvic organs should be made."

A chapter is devoted to the modes by which cancer of the uterus spreads and to its recurrence after an operation, and the chapter is an exceedingly good one. It includes a consideration of the modes of death from cancer, the chief of which, the author thinks, is by uræmia resulting from changes such as hydronephrosis and pyonephrosis produced in the kidneys in consequence of involvement of the ureters by reason of invasion of the pelvic cellular tissue.

Appropriate operations are advocated for the removal of the various forms of uterine cancer, and they are well described. The author is very hopeful of a virtual cure by operations done sufficiently early. Abdominal hysterectomy, for some years past practically supplanted by the vaginal operation, has again been introduced, he says, and he justly adds that the improvements in the operation are "really all modelled on the original plan adopted by Freund." The transverse suprapubic incision, he thinks, offers considerable advantages in providing more working space and better exposure of the pelvic contents in cases of involvement of the parametrium, but he doubts the advisability of an operation in such advanced instances.

Palliative treatment and the management of inoperable cases are duly considered, though we find no mention of the employment of the Röntgen rays or of radium. In the section dealing with the treatment of the patient after an operation there is no discussion of the length of time for which confinement to bed is judicious. Some of the terms employed are a little puzzling at first—for example, "Brom alcohol" (with a capital B, page 103), though this, without the capital, is said on page 105 to be composed of one part of bromine and five parts of rectified spirit. "Bortannin" does not seem to be explained.

On the whole, the book is a solid addition to the literature of a most important subject, and one of a very practical character. As we have intimated, its usefulness will not be confined to operating surgeons, but will extend to all practitioners.

*A Manual of the Practice of Medicine.* Prepared Especially for Students. By A. A. STEVENS, A. M., M. D., Professor of Therapeutics and Clinical Medicine in the Women's Medical College of Pennsylvania, etc. Eighth Edition, Revised. Illustrated. Philadelphia and London: W. B. Saunders Company, 1907. Pp. 558. (Price, \$2.50.)

The first edition of this book appeared fifteen years ago. New material has been added, and many articles, especially in the section dealing with diseases of the nervous system, have been rewritten. The nomenclature in the prescriptions has been changed according to the new (eighth) revision of the pharmacopœia. It is one of the very few books in which the author has taken the trouble of revising the

pharmacological terms in his new edition. The book has thus been brought up entirely to date.

Dr. Stevens's book has always been well known for the practical hints it gives in the treatment of diseases and the great number of good prescriptions it contains. Thus it has become a valuable adjuvant for the senior student and a welcome compendium for the practitioner.

*Diagnostico y Tratamiento de las Enfermedades de las Vías Urinarias.* Lecciones Elementales. Por ALBERTO SUAREZ DE MENDOZA. Profesor de Enfermedades de las Vías Urinarias en la Facultad de Medicina de Madrid. Cirujano de la Casa de Salud de Nuestra Señora del Rosario. Perledo, Paez y Cia, 1908. Pp. 790.

This volume presents a series of lectures on urology delivered to the medical students at Madrid. As might be expected, the author follows largely the French school, that of the Necker Hospital, where Guyon taught so long and where Albarran now holds his clinical courses. The subject is handled with great completeness and thoroughness, and the book will make interesting reading for those who wish to familiarize themselves with medical Spanish and who desire to practise urinary surgery in a Spanish speaking country. In other respects the book offers nothing special to those who have works in French, German, or English on the same subject in their libraries.

*Abell's Laboratory Handbook of Bacteriology.* Translated from the Tenth German Edition, by M. H. GORDON, M. A., M. D. (Oxon.), B. Sc., with Additions by Dr. A. C. HOUSTON, Dr. T. J. HORDER, and the TRANSLATOR. London: George E. Arnold (Oxford University Press) and Hodder & Stoughton, 1907. Pp. x-224.

Bacteriology has become an indispensable aid in correctly diagnosing infectious diseases, and while every physician is required to have a general knowledge of the subject, medical officers of cities or States must be thoroughly conversant with this branch of the medical sciences. The present pocket edition, an abbreviated and condensed translation, provides those studying bacteriology with a guide for practical laboratory work. But not only will medical men find it very instructive, but the veterinary surgeon, the druggist, and the chemist will have in this compendium a handy assistant.

The translation has been well done, so far as we can judge, and several chapters contain revisions and amplifications by the English authors.

The book may be divided into three parts: Introduction and general methods of staining (pp. 1 to 81, chapters i to v); special staining and culture methods for certain bacilli (pp. 82 to 159, chapter vi); chapters vii to xii, pp. 160 to 218, containing synopses of methods of obtaining material from the body for bacteriological examination, methods of examining blood in relation to immunity, inoculation and post-mortem examination of animals, methods of preparing preparations for bacteriological examination of water, milk, shellfish, sewage, soil, dust, air, etc.

*Immunity and Inoculation.* By SCOTT G. M. D. Fellow of the Royal College of Physicians, etc. London: Henry Kimble (Oxford University Press) and Dublin & Glasgow, 1907. Pp. xiv-87.

This is the fifth edition of a very useful and practical book. Although chapters on inoculation and prevention of the chest are to be found in every

textbook of medicine, the methods of physical examination are of such importance that the subject well deserves, as it has amply received, complete treatment in books devoted especially to them. The author has excluded x ray examinations, as he thinks the necessary apparatus is too expensive to be within reach of every practitioner.

The book is divided into two parts. Part I treats of the physical signs in abstract, giving the pure science, while Part II considers these signs in their subservience to the discovery of disease, giving thus the applied science of these signs.

*Laboratory Guide to the Modelling of the Human Bones in Clay.* By VERRAY PAPIN BLANC, A. M., M. D., Associate Professor of Anatomy, Medical Department, Washington University. St. Louis: Cooperative Association of the Medical Department of the Washington University. Pp. 69.

This book is a very interesting one, although we doubt if this new system of teaching osteology will find a place in the already overcrowded curriculum of junior medical students. The method itself seems to be very advantageous, as the student will receive a good idea of the shape and form of the bone he is modelling. Names and descriptions can be easily memorized, and will answer for a theoretical examination. But the old saying *non scholæ sed vitæ discimus* is so often forgotten that this practical course of osteology will be of great help in remembering the normal shape of a bone. But not every medical student can become a modeller, and it needs the skill and the eye of an artist to imitate nature. The medical student will hardly find time to adapt himself to the necessary technique of handling clay and producing models which will really answer the requirements.

*The Treatment of Fractures.* With Notes upon a Few Common Dislocations. By CHARLES LOCKE SCUDDER, M. D., Surgeon to the Massachusetts General Hospital; Lecturer on Surgery in the Harvard University Medical School. Sixth Edition, Thoroughly Revised and Enlarged. With 856 illustrations. Philadelphia and London: W. B. Saunders Company, 1907. Pp. 628.

In this, the sixth edition of Scudder's well known book on fractures, special attention has been paid to obstetrical fractures of the skull in the new born (chapter i); fractures of the zygoma, malar bone, and superior maxilla (chapter ii); of the head and neck of the radius (chapter x); of the neck of the femur (chapter xii), etc., and to the nonunion of fractures. A few illustrations have been added, especially those referring to x ray examinations. The new edition will add to the well merited renown of the book.

*Hospital Training, School Methods and the Home Training.* By CLARETTE A. ALLEN, Art Director at Santa Monica, and Hester W. Morgan, D. C., Art Professor, etc. and London: W. B. Saunders Company, 1907. Pp. xiv-100, 32 plates, 32 cuts.

This is a very interesting book, written by an author who has had much experience in the training of nurses and superintending of hospitals. She very rightly remarks in her preface that "in the beginning of the era of trained nursing in America we were satisfied with a rudimentary training. Little by little this has been added to until at the present time a hospital which admits a pupil to its training department is expected to carry her in at the hospital

garten stage in nursing, and conduct her by a swift high pressure system clear through the university stage all in the short space of two or three years."

Out of her great store of knowledge Miss Aikens discusses the training school problem, speaks about plans that have stood the test, and advises teachers and superintendents of hospitals. Of textbooks on nursing we have a goodly number, but very few, if any, books on the method of teaching and superintending.

The book is divided into two parts: Hospital Training School Methods, and the Head Nurse. Some of the chapters have appeared in the *Canadian Nurse* and the *National Hospital Record*, but are here collected for the first time. Both parts are well constructed and contain interesting material. The author represents the proper viewpoint and is opposed to the new method, which seeks to make a graduated nurse know as much as a graduated physician. The hospital training school should certainly teach nursing from its very foundation, while postgraduate training schools should go beyond these essentials.

*Surgical Applied Anatomy.* By Sir FREDERICK TREVES, Bart., G. C. V. O., C. B., LL.D., F. R. C. S., etc. Fifth Edition, Revised by ARTHUR KEITH, M. D., F. R. C. S., Lecturer on and Senior Demonstrator of Anatomy at the London Hospital, etc. Illustrated with 107 Figures, including 41 in Color. Philadelphia: Lea Brothers & Co., 1907. Pp. 640.

Some sections of this revised edition have been entirely rewritten, while to others much new matter has been added. The illustrations are clear and to the point. A very complete index and the size of the book make it a very handy compendium. Although mainly intended for the use of senior students, it will prove of value to the general practitioner.

#### BOOKS, PAMPHLETS, ETC., RECEIVED

*Lectures on Medical Jurisprudence and Toxicology as Delivered at the London Hospital.* By Fred J. Smith, M. A., M. D., F. R. C. P., F. R. C. S., Physician to and Lecturer on Forensic Medicine at the London Hospital, etc. Second Edition. London: J. & A. Churchill, 1908. (P. Blakiston's Son & Co., Philadelphia.) Pp. xiv+463.

*Woman. A Treatise on the Normal and Pathological Emotions of Feminine Love.* By Bernard S. Talmey, M. D., Gynecologist to the Yorkville Hospital and Dispensary, etc., New York. For Physicians and Students of Medicine and Jurisprudence. With Twenty-three Drawings in the Text. Second Enlarged and Improved Edition. New York: Practitioners' Publishing Company, 1908. Pp. x+258.

*Vorlesungen über Diätbehandlung innerer Krankheiten vor reiferen Studierenden und Aerzten.* Von Dr. H. Strauss, in Berlin. Mit einem Anhang "Winke für die diätetische Küche" von Elise Hannemann. Berlin: S. Karger, 1908. Pp. 340.

*A Textbook of Surgical Anatomy.* By William Francis Campbell, M. D., Professor of Anatomy, Long Island College Hospital, etc. With 319 Original Illustrations. Philadelphia and London: W. B. Saunders Company, 1908. Pp. 675. (Price, \$5.)

*Sprachstörungen und Sprachheilkunde. Beiträge zur Kenntnis der Physiologie, Pathologie und Therapie der Sprache.* Unter Mitwirkung von E. Bloch, Boodstein, M. Bresgen, Brühl, Panconcelli-Calzia, F. Frenzel, H. Knopi, O. Lanbi, E. Maschke, Hudson-Makuen, A. Mielecke, Nadolcezný, Oeconomiakís, W. Oltuszewski, H. Piper, G. Golecz, Rouma, A. v. Sarbó, K. L. Schaefer, H. Söder, H. Stern, E. Stötzner, E. Winckler, and H. Zwaardemaker, herausgegeben von Dr. med. H. Gutzmann. Privatdozent

Transactions of the College of Physicians of Philadelphia. Third Series, Volume XXIX. Philadelphia, 1907. Pp. 150

#### Miscellany.

**Resolutions on the Death of Dr. Daniel B. St. John Roosa.**—The following resolutions were adopted at a regular meeting of the Alumni Association of the New York Postgraduate Hospital, held Tuesday evening, March 10, 1908:

We meet to-night under the shadow of a great affliction, so sudden, so unexpected, that we have not yet realized how great it is. It will not be easy to fill the position Dr. Roosa's death has left vacant. It probably never will be filled. The work will continue. The medical school his mind conceived has become an established fact, an integral part of the educational system of the State, while the hospital he founded and over whose destinies he has presided for the past twenty-five years has become an important factor in the charitable work of New York. No one else occupying the position of president will ever be able to hold all those connected with the institution to their duties through sheer loyalty to the president. This Dr. Roosa has done most successfully, binding all together in a determination to carry on the work of our institution, no matter what disappointments were met, no matter what obstacles were put in the way, simply because he wanted it—not for himself, but to attain the great object that he had in view.

Dr. Roosa was a strong man, a man of broad education and culture, and his great success as a teacher, as an administrator, as a practitioner of his specialty, came from the force of his intellect and the power he had of presenting facts clearly and cogently. This made him a natural orator, and led him to take an interest in affairs outside of medicine. He was a national man, a cosmopolitan man.

He will ever be remembered as the founder of systematized postgraduate instruction for medical men. His was the original conception of the idea which has since been copied throughout the world.

We who have served on the house staff of the New York Postgraduate Hospital during the past twenty-five years feel his loss the more keenly because we were made to feel throughout the years of our association with him that he was especially interested in our welfare, not only during our service in the hospital, but during after life. We have all felt his kindly sympathy, and we will all miss the cordial tone with which he used to meet us and inquire of our successes or sympathize with our failures.

Of him we cannot speak as we would. It is said of Sir Christopher Wren, the architect of St. Paul's Cathedral, London, that he did more to beautify the city than all the architects of a hundred years. He lies in a vault in St. Paul's, and above his sleeping dust is a simple slab bearing this inscription: "Here lies Sir Christopher Wren, architect. Would you see his monument? Then look about you." So Dr. Roosa has built his monument in the New York Postgraduate Medical School and Hospital, and in every other institution, the world over, devoted ex-

clusively to the systematic instruction of graduates in medicine. He has put his time, his energy, his brain, his heart, *himself* into the great work. The powers thus set in motion for the uplifting and education of the medical profession and the amelioration of the ills of suffering humanity are as far reaching and immeasurable as eternity.

We thank God that Dr. Roosa lived. We thank God that we have had our medical training under the influence of his precept and example.

To Mrs. Roosa and his family we offer not the perfunctory sympathy of a medical society, but the sympathy of those who loved, admired and revered him.

His memory will live with us as long as any of us may survive.

For the association,

FRANKLIN A. DORMAN,  
EDWARD W. PETERSON,  
DOUGLASS W. CAIRNS,  
SAMUEL LLOYD, Chairman.

**Vivisection.**—The subjoined letter was recently forwarded to each member of the Judiciary Committee of the Senate and Assembly of New York by Dr. J. Leonard Corning, of New York:

DEAR SIR:—The undersigned respectfully requests that you will use your influence as a member of the Judiciary Committee of the Assembly to prevent the recommendation or passage of any bill in restraint of the liberty of physicians to conduct experiments on living animals with the purpose of augmenting medical knowledge, and thereby conducing to the welfare of the public.

My reasons for putting forward this request are as follows:

1. Experiments on animals, vivisection, as it is sometimes called, are absolutely indispensable expedients to physiologists, pathologists, physicians, and surgeons. By their aid physiologists are able to discover the nature of the vital processes; pathologists to determine the effects on the different organs and on the organism as a whole of various disease breeding agencies, and devise means for the counteraction of such agencies; physicians to test the effects of remedies on the animal organism before venturing to prescribe them for their patients, whether in hospitals or in private practice; while surgeons are enabled to devise and perfect new and salutary operations, and thus insure the success of the latter before performing them on human beings.

2. By virtue of the knowledge derived largely by experiments on the lower animals it is now possible to prevent or abort epidemic diseases that formerly swept on to death whole populations; among such diseases are cholera, and yellow fever.

3. Thanks to experiments on animals, a serum is now prepared that enhances the prospects of recovery from diphtheria enormously. This is proved by the astounding fall in the percentage of fatalities from the disease in all the great cities of the world where the serum has been consistently and generally applied.

4. To prepare a serum of this kind and to discover new and valuable remedies that the experiments on animals are absolutely indispensable.

5. All new remedies should be, and usually are, tried on animals before finding an application in hospital and private practice. By such trials it is possible to ascertain how they act in different doses used in proportion to the weight of the animal, so that when applied on human beings, some of the most fatal mistakes are avoided. In many instances, might result in death. Again, by experiments on animals, it is possible to ascertain the effects of different remedies on the individual organs and the organism as a whole, and to determine the best way to apply them. In many instances, the results of the experiments on animals are so valuable, that it will be desirable to apply them.

6. The experiments on animals are of such importance, that it is necessary to have a large number of animals for the purpose.

been made that, were we to-day bereft of them, medical science would be thrust back into the barbarous ignorance that characterized it during the Dark Ages.

7. An impartial and thorough analysis of medical history by competent criticism cannot fail to reveal the fact that experimentation on animals has to a large degree served to advance medical science more in the last fifty or sixty years than in the previous five hundred.

8. That physicians should be urged to continue experimentation on animals is of vital importance to the present and future well being of the public. Restrict their privileges in this regard; dampen their zeal by ill considered, galling regulations, and you drive to apathy and cynicism a kind of intellect that, if encouraged to go on, would, as in the past; add achievement to the resources of a profession, the conservation of whose ideals and whose advancement upon the road of reason are of vital importance to the moral and physical well being of every civilized community.

9. The following are a few of the more striking results achieved by vivisection: The discovery of the motor centres in the brain; discovery of the functions of the sympathetic nervous system; the demonstration of the difference in function between the anterior and posterior roots of the spinal nerves; important discoveries in the physiology of the spinal cord; demonstration of nervous influence on secretion; discovery of the nervous mechanisms of the heart; discovery of transcendent facts in the physiology of digestion; implantation of bone, i. e., the removal of bone from an animal to a human being; patching of bloodvessels; working out of important operations on the intestines; working out important operations on the brain; suture of nerves—these are but a fraction of the results obtained by resort to the only method by which their accomplishment could have been made possible.

53 WEST THIRTY-EIGHTH STREET.

## Public Health and Marine Hospital Service:

*Official list of changes in the stations and duties of commissioned and noncommissioned officers of the United States Public Health and Marine Hospital Service for the seven days ending March 14, 1908:*

- CUMMING, H. S., Passed Assistant Surgeon. Directed to proceed to Kobe, Japan, for special temporary duty, upon completion of which to rejoin his station.
- DE VALIN, HUGH, Assistant Surgeon. Granted leave of absence for two days from March 3, 1908, under paragraph 191, Service Regulations.
- DUKE, B. F., Acting Assistant Surgeon. Granted leave of absence for seven days from March 10, 1908.
- FROST, W. H., Assistant Surgeon. Granted leave of absence for two days from February 29, 1908, under paragraph 191, Service Regulations.
- OAKLEY, J. H., Passed Assistant Surgeon. Directed to assume temporary charge of the Marine Hospital at Port Townsend, Wash., during the absence of Surgeon W. G. Stimpson.
- PETTUS, W. J., Assistant Surgeon General. Granted leave of absence for three days from March 9, 1908.
- STANTON, J. G., Acting Assistant Surgeon. Granted an extension of leave of absence for seven days from March 6, 1908.
- STIMPSON, W. G., Surgeon. Directed to report to the commanding officer of the revenue cutter *Thetis* for temporary duty.
- VON ELDORF, R. H., Passed Assistant Surgeon. Directed to proceed to New Orleans, La., for special temporary duty, upon completion of which to rejoin his station.
- WETMORE, W. O., Acting Assistant Surgeon. Granted leave of absence for eight days in February, 1908, under paragraph 210, Service Regulations.

## Army Intelligence:

*Official list of changes in the stations and duties of officers serving in the medical department of the United States Army for the week ending March 14, 1908:*

- BRATTON, T. S., Captain and Assistant Surgeon. Upon arrival at San Francisco, Cal., will proceed to Fort Des Moines, Ia., and report in person to the commanding officer of that post for duty, and by letter to the commanding general, Department of the Missouri.
- CARSWELL, R. L., Captain and Assistant Surgeon. Granted two months' leave of absence, with permission to apply for an extension of one month.
- CORRISSIER, W. H., Lieutenant Colonel and Deputy Surgeon General. Relieved from further duty as chief surgeon, Department of the Columbia, and will proceed to Fort Leavenworth, Mo., where, for his own convenience, he is authorized to await retirement from active service.
- FRANKLIN, M. B., Lieutenant Colonel and Deputy Surgeon General. Appointed a member of an Army retiring board, to meet at Omaha, Neb., for the examination of retired officers, to be held before it.
- REASONER, M. A., First Lieutenant and Assistant Surgeon. Relieved from further duty in the Philippines Division, and assigned to duty in the Army Transport Service, with station at San Francisco, Cal.
- ROBERTSON, C. D., First Lieutenant and Assistant Surgeon. Granted leave of absence for three months.

VAN DUSEN, J. W., Captain and Assistant Surgeon. Appointed a member of an Army retiring board, to meet at Omaha, Neb., for the examination of such officers as may be ordered before it.

WILSON, W. H., Major and Surgeon. Detailed to accompany the Thirty-fifth Company, Coast Artillery Corps, from Fort Monroe, Va., to San Francisco, Cal., proceeding at the proper time to Fort Monroe, Va., reporting upon arrival to the company commander; upon completion of this duty, ordered to return to Fort Hamilton, N. Y.

## Navy Intelligence:

*Official list of changes in the medical corps of the United States Navy for the week ending March 14, 1908:*

- BOGERT, E. S., JR., Surgeon. Detached from the *Pennsylvania* and ordered to the Naval Academy.
- BROWN, E. M., Passed Assistant Surgeon. Granted sick leave for three months, when discharged from treatment at the Naval Hospital, New Fort Lyon, Col.
- MORAN, C. L., Assistant Surgeon. Ordered to duty at the Naval Hospital, Norfolk, Va.
- RICHARDS, T. W., Surgeon. Detached from the *Colorado* and ordered to the Naval Hospital, Mare Island, Cal., for treatment.
- STANLEY, A. C., Assistant Surgeon. Ordered to duty at the Naval Medical School Hospital, Washington, D. C.
- URIE, J. F., Surgeon. Detached from the Bureau of Medicine and Surgery, Navy Department, and ordered to the *Pennsylvania*.

## Births, Marriages, and Deaths.

### Married.

- BORST-BRYANT.—In Framingham, Massachusetts, on Monday, March 9th, Dr. Theodore F. Borst and Mrs. Sara Cone Bryant.
- DAGG-McGEE.—In Kansas City, Missouri, on Tuesday, February 25th, Dr. G. R. Dagg and Miss Maud McGee.
- MAVERICK-BAXTER.—In Philadelphia, on Thursday, March 5th, Dr. Augustus Maverick and Miss Elizabeth A. Baxter.
- ROSENHECK-GOTSDANKER.—In New York, on Sunday, March 8th, Dr. Charles Rosenheck and Miss Leonora Gotsdanker.

### Died.

- BRANNEN.—In Washington, D. C., on Wednesday, March 4th, Dr. Dennis J. Brannen, of Flagstaff, Arizona.
- DU BOIS.—In Hyde Park, New York, on Monday, March 2d, Dr. Mary Du Bois.
- DUNLOP.—In New York, on Friday, March 6th, Dr. Clark W. Dunlop, aged sixty-three years.
- GIBERSON.—In Beverly, New Jersey, on Saturday, February 29th, Dr. William H. Giberson, aged forty years.
- HARLOW.—In Tyngsboro, Massachusetts, on Tuesday, March 10th, Dr. Granville A. Harlow, aged fifty years.
- HOLDEN.—In Paris, France, on Friday, February 28th, Dr. Francis M. Holden, of Philadelphia, aged fifty years.
- KENNEDY.—In Springfield, Massachusetts, on Wednesday, March 11th, Dr. Charles Francis Joseph Kennedy, aged forty-one years.
- RICHARDSON.—In Belair, Maryland, on Saturday, March 7th, Dr. E. Hall Richardson, aged forty years.
- SADLER.—In Montgomery, Alabama, on Saturday, March 7th, Dr. John M. Sadler, aged fifty-eight years.
- SAMMONS.—In Chicago, on Thursday, March 5th, Dr. E. H. Sammons, aged fifty-eight years.
- SAMUELS.—In St. Joseph, Missouri, on Monday, March 2d, Dr. Reuben I. Samuels, aged eighty-two years.
- SEMPLE.—In Philadelphia, on Thursday, February 27th, Dr. William H. Semple, aged forty-three years.
- TIBBETTS.—In Newville, New York, on Wednesday, March 11th, Dr. William Tibbetts, aged seventy years.
- WHITE.—In Lancaster, New Hampshire, on Sunday, February 23d, Dr. A. Campbell White, of New York, aged thirty-nine years.
- WOODRUFF.—In St. Augustine, Florida, on Sunday, March 8th, Dr. E. D. Woodruff, of Monroe, New York.
- WYMAN.—In Detroit, Michigan, on Monday, March 9th, Dr. Hal C. Wyman, aged fifty-six years.

#### THE ACCESSORY SINUSES OF THE NOSE FROM AN OPERATIVE STANDPOINT.\*

By HARMON SMITH, M. D.,  
New York,

Surgeon, Manhattan Eye, Ear, and Throat Hospital; Instructor in Clinical Laryngology, College of Physicians and Surgeons, Columbia University.

In the following paper I shall take up the subject of sinusitis where operative measures of a more radical nature are imperative, either to save life or because palliative treatment and minor surgical measures have failed.

When empyema of the maxillary sinus has existed for a long time, and irrigation through the ostium, or through an ill advised opening in the alveolar process, or through a small opening in the inferior nasal fossa, has failed to make favorable headway against the disease, a more radical procedure is necessary.

The Caldwell-Luc operation has been employed successfully for a number of years, and with the drainage taking place into the nose it has many features to recommend it. However, it now appears unnecessary to enter the sinus externally in the majority of instances, for sufficient drainage is obtained and complete recovery accomplished by entering the sinus in the following manner:

Inject into the mucous membrane over the anterior half of the inferior turbinate and into the mucous membrane over a corresponding area of the inferior fossa one half of one per cent. solution of cocaine, and sufficient adrenalin solution of 1 in 5,000 strength to bleach the parts. The anterior part of the inferior turbinate is then removed. A tongue shaped flap of mucous membrane can be detached from the bone at the site of the desired entrance into the antrum by cutting two vertical parallel lines, the first one from a point just anterior to the cut end of the inferior turbinate downward to the floor of the nose, the second about half an inch farther forward and parallel to the first. These two are connected by a third cut between their upper extremities. With a small periosteal elevator, such as Freer's, the mucous membrane can easily be detached from above downward and turned back into the floor of the nose for subsequent use. Then with Abraham's pyramidal punch easy entrance may be made into the antrum at the upper extremity of this denuded area. After entrance has been gained with this punch Abraham's

olive pointed burr is introduced, and with a backward and forward movement the original entrance may be enlarged to the full width of the denuded bone and also lowered to the floor of the nose, which opening should be sufficiently large to permit of removing from the antrum most of the polypoid material therein.

After this procedure the hæmorrhage is controlled by packing the antrum with gauze soaked in adrenalin or pure alcohol. This packing should then be removed and the tongue shaped flap of mucous membrane turned into the antrum and held in position on the floor by dry boric acid gauze packing. This packing should be fed into the antrum so that it will run in layers from the floor to the roof and can be withdrawn gradually from above downward, beginning on the second day. This method of removal permits the mucous membrane to become attached before the removal of gauze immediately in contact with it tends to tear it from its place. I think, however, that the importance of this mucous membrane flap is overestimated. In persistent cases, tight packing is necessary for a period of many weeks. Just as tight packing facilitates the healing of a radical mastoid operation, so does it act in keeping down granulations in the antrum.

In cases where no polypi exist in the antrum, the free drainage and frequent irrigation with hot normal saline solution will readily overcome the purulent condition. If for any reason, such as carious bone, a pocket of pus out of reach of the packing, or the root of some decayed tooth, this operative method should not succeed, then recourse may be had to the more extensive one of Caldwell-Luc, in which case that part of the operative procedure which connects the antrum with the nose will already have been performed.

*The Sphenoidal Sinus.*—The surgery of this sinus has been greatly developed by rhinologists during recent years, so that it is no longer regarded as a part of orbital surgery. Natural drainage here is difficult, owing to the elevated position of the foramen of exit, so that the escape of the secretions must be due largely to the ciliary motion of the epithelial lining. Therefore an empyema here not only produces difficulties *per se*, but also endangers the cranial cavity by contiguity, meningitis of the base being readily set up by extending inflammation through the blood and lymph vessels. In investigating the sources of intracranial suppuration, not a few are found to be due to pus in the sphenoidal sinus, as is demonstrated by the following cases cited by St. Clair Thomson. Such cases are common.

\*Read before the Wednesday Medical Association, New York, 1907.

rally difficult of diagnosis, being both obscure in character and insidious in course.

The method of entering this sinus through the nose is as follows: The middle turbinate is first removed and the anterior and most of the posterior

FIG. 1.—2. The flap of mucous membrane detached from the lateral wall of the nasal chamber under the inferior turbinate; b, the remaining portion of the inferior turbinate after the removal of the anterior third; c, the approximate size of the opening into the antrum Highmore necessary to evacuate the products of chronic suppuration.

ethmoidal cells curetted away. The anterior wall of the sphenoidal sinus may then come into view. A small sinus lamp should be employed in the examination. Measurements should be taken, when the results will be about as follows: The anterior wall of the sphenoidal sinus is about eight centimetres from the vestibule. A sinus probe, slightly curved, follows the vault of the nasal fossa, and should then enter the sphenoidal sinus through its ostium. A curette should be introduced along the probe into the sinus, whereupon the anterior wall of the latter may be broken down by drawing the instrument downward and backward. Elongated forceps, such as Kerrison's, are used to enlarge the opening, fragments of bone tissue being pinched away. When the cavity is thoroughly exposed drainage is not only established, but polypi, purulent mucosa, etc., may be scraped away. If necrotic bone is present it should also be curetted, but this operation is very dangerous when the roof of the sinus is necrosed, on account of the close proximity of the brain. Trephines, saws, etc., are used to enter the sphenoidal sinus, although they are more dangerous than the curette.

The sinus should be cleansed and packed with iodoform gauze, which is removed the next day. It is well to apply strong silver nitrate solution to the cavity, or at least its border, after a few days, in order to cut down granulations.

Trendelenburg position: This has both advantages and disadvantages, although in the main it is essential to operative success. Its advantages are obvious, while its drawbacks include the difficulty of choosing the proper route for curettement.

The operator must be careful not to direct the instruments too high up, as there is danger of entering the cranial cavity. The maxillary route is by far the easiest and safest, provided a Caldwell-Luc operation on the antrum has been necessary.

*Frontal Sinus.*—When convulsions, coma, chill, followed by high temperature, or the evacuation of pus into the orbit occurs in the course of frontal sinus suppuration, radical procedures are clearly indicated. Comparative comfort may be experienced by the patient for a number of years by the removal of the anterior end of the middle turbinate and careful opening into the "hiatus semilunaris," giving drainage to the sinus.

The internal operation upon the frontal sinus is usually condemned because of its dangers, but Ingals, of Chicago, has devised a small guarded trephine which is directed by a probe along a proper and safe course into the cavity. I have never used this instrument, but it appears to be the safest for all intranasal measures. This method, however, would serve only to give drainage, and would by no means tend to overcome the numerous foci of infection walled off by septa of bone, such as are frequently found in a sinus. Numerous operators have devised and advocated special methods for gaining entrance externally into this sinus without producing subsequent deformity. The first of these was Callisen, in 1798. The modern idea, as advocated by Jansen, Killian, Coakley, and others, is to thoroughly cleanse the sinus, remove the ethmoid cells, enlarge the nasofrontal duct, and minimize deformity. For a small sinus showing no bony septa upon the skiagraphic plate, Jansen's opera-

FIG. 2.—From Killian's *Snuggers*, iii, p. 136. Fig. 200 (Killian's Operation). First Step.—Showing line of initial incision with slight transverse cutaneous cuts. The initial incision is made through the soft structure to the periosteum.

tion may well be advocated, and, briefly described, is as follows:

A curvilinear incision is made just above and parallel to the eyebrow, beginning at the external

orbital angle and terminating at the middle of the root of the nose. The soft tissues and periosteum are then detached from the roof of the orbit, which is the floor of the sinus, by the use of the periosteal elevator. The roof of the orbit is then removed

FIG. 3.—From Keen's *Surgery*, vol. p. 437, Fig. 270 (Killian's Operation). Second Step.—Showing soft tissues retracted, and lines of periosteal incisions.

with a curette. The sinus is curetted and the nasofrontal duct is enlarged. A drainage wick of gauze is introduced from the sinus into the nose through the duct, and a second drainage wick is placed in the lower internal angle of the wound. The orbital fat is supposed to fill the excavated sinus. If the sinus is large and has numerous septa, proper cleansing is impossible. If it is small and undivided, good results will be obtained both surgically and cosmetically.

The operation which now recommends itself to most operators and which is being pursued with a minimum of evil results is that of Killian, of Freiburg.

First step.—The brow is not shaved, but clipped, and the incision is made through the hair line of the brow from the temporal extremity of the orbit to the root of the nose, dividing the nasal section of the musculus quadratus in the centre of the frontal process of the superior maxilla. This incision ends in an oblique curve outward below the base of the nasal bone. The line of incision is marked by slight transverse cutaneous cuts, which enable the operator to properly coapt the wound after operation and thus lessen the tendency to deformity. After this primary incision is made through the soft parts to the periosteum, the soft tissues are lifted away from the periosteum, uncovering the external plate of the frontal bone above the arch and the roof of the orbit below, and the nasofrontal suture beyond the median line.

Second step.—Periosteal incisions.—(a) An incision is made through the periosteum parallel to the supraorbital margin and five to six millimetres

above, extending from the temporal end of the eyebrow to the beginning of the root of the nose at its central point. (b) A second periosteal incision is made, beginning just internal to the attachment of the pulley of the superior oblique muscle and following the line of the cutaneous incision to its extremity. The periosteum is then elevated from the superior incision over the entire anterior frontal wall and from the inferior incision downward, exposing the inner and superior third of the orbit. These elevations leave a strip of periosteum covering the site of the bony arch left for the purpose of sustaining the soft tissues after closing the wound and giving nourishment to the bone beneath.

Third step.—Enter the sinus by means of a gouge and mallet just above that piece of bone included between the periosteal incisions.

Fourth step.—With a probe ascertain the extent of the sinus.

Fifth step.—By means of a gouge and mallet ex-

FIG. 4.—Killian's Operation. Third Step.—Showing the sinus entered by means of a gouge and mallet just above that piece of bone included between the periosteal incisions. The sinus is then entered by means of a gouge and mallet just above that piece of bone included between the periosteal incisions. The sinus is then entered by means of a gouge and mallet just above that piece of bone included between the periosteal incisions.

cavate a groove through the external table from the first opening into the sinus to the external extremity.

ity of the sinus. This groove will then permit the free use of the chisel in removing the remainder of the bony covering of the sinus, without endangering the arch, which it is desirable to retain intact. The entire bony covering of the sinus is thereby removed, and considerable care exercised to uncover properly the angles of the sinus.

Sixth step.—Thoroughly remove all contents of the sinus and its mucous membrane, also break down all existing bony septa, so that free inspection of the sinus may be made throughout. Hæmorrhage will frequently be profuse until all granulation tissue is removed.

Seventh step.—Remove the floor of the sinus without injury to the supraorbital ridge, which enters into the arch of bone left standing. This procedure may best be accomplished by the operator standing behind the patient's head and chiseling

FIG. 5.—(Killian's Operation). Lateral appearance after dividing the head. *a*, Entrance through os planum and orbit into the ethmoidal tract. *b*, The ethmoidal tract. *c*, Sphenoidal sinus. *d*, Line of attachment of middle turbinate. *e*, Inferior turbinate.

from above downward. The bone is thin and can easily be removed without endangering the contents of the orbit.

Eighth step.—Remove the frontal process of the superior maxilla and the remaining part of the sinus floor.

Ninth step.—Remove the ethmoid cells, both anterior and posterior, if diseased, and the middle turbinate bone. Likewise remove the anterior wall of the sphenoid and curette this cavity if it is involved. Grünwald's forceps are serviceable in performing this operation. In order to reach the posterior ethmoidal cells, and the sphenoid, it is frequently necessary to chisel away part of the nasal bone on the side involved. This does not complicate matters in the general healing of the wound.

Tenth step.—Irrigate the wound with salt solution and dust with iodoform. Run a gauze wick from the temporal extremity of the frontal sinus into the nasal chamber through the frontonasal canal and terminate at the nasal vestibule. The incision is then sutured with the expectation of primary union. Care is exercised in the coaptation of

the wound, and the little cuts previously made across the first incision materially aid in this matter.

After treatment.—Place the patient on the healthy side. Give strict orders that he shall not blow his nose, but must aspirate the secretions flowing from the wound. Dressing must be done daily, but no irrigation must be used. The gauze packing is removed on the second day, and the sutures on the fourth to the fifth day. Care of the wound internally must be continued over a period of two to six months. This after treatment is tedious, and the after granulations springing up must be cut down with a strong silver nitrate solution. Even fused silver nitrate on a probe is necessary in many instances.

Deformity frequently results from this operation, in the form of a depression above the bony arch, which is left to support the tissues. This depression has been filled in by the subcutaneous injection of paraffin, which overcomes the deformity. For a long time after the operation a soft, mushy condition may be felt in the angle of the orbit, and sometimes a fistula forms at this point.

Dangers.—Many deaths have followed these operations, in which the operator could in no wise hold his technique responsible; and fatal terminations have been reported by such eminent operators at St. Clair Thomson, Herbert Tilley, Burghard, Lambert Lack, Milligan, and Logan Turner. I have seen most excellent results from operations by Thomson, Tilley, and Lack, and firmly believe that no fault of theirs contributed to the fatal results. I would emphasize the importance of serious consideration before attempting the radical operation:

1. Consider the close proximity of the brain.
2. The many avenues of infection opened up by the exposure of such an extensive area.
3. The limited knowledge of the sphenoidal sinus and the posterior ethmoidal cells obtainable by direct observation, and the necessity of relying almost entirely upon one's knowledge of the anatomy of the parts for operative measures.
4. The possibility of an already existing meningitis; for not infrequently cases are sent in for operation with a high temperature, some mental aberration, perhaps delirium, choked disc, and other symptoms which could be attributed either to pus under pressure or to an existing meningitis.
5. The lowered vitality and resistance of the patient, which predisposes to both infection and pneumonia.

Before leaving the subject I would emphasize the material aid offered by skiagraphy, not only in diagnosing empyema of the sinus, but in outlining the probable extent of the operation. In the frontal sinus particularly it is important to know the size of the cavity, whether it is multilocular or presents an orbital recess, and, finally, whether the sinus is diseased. The last factor is determined by the milky appearance of the sinus in contrast with the dark appearance of the unaffected side. The skiagraph also demonstrates the width of the ethmoid cell area and its relation to the frontal sinus. Just as it is essential to become acquainted with the ophthalmoscope and its readings in the eye, so is it necessary to study a number of skiagraphs and follow their teachings by operative demonstration, in order to become proficient in deciphering the shades

and shadows exposed in the plate. One familiar with this subject can deduce many truths from a skiagraphic plate which an unaccustomed eye could never perceive.

In closing I would advise against too much aggressiveness in radical operation upon either sphenoidal, ethmoidal, or frontal sinuses—the maxillary is farther removed from danger—for I believe that a great many suppurative conditions can be cured by securing perfect drainage. I also believe that it is of vital importance that one should be perfectly familiar with these areas before attempting to curette in such close proximity to meningeal tissues. Even when the operator is perfectly familiar with the anatomy he may induce meningeal infection by stirring up infected areas adjacent to venous and lymph channels which lead directly to the base of the brain.

### THE RADIOGRAPHIC TOPOGRAPHY OF THE FRONTAL SINUS AND OTHER PNEUMATIC SINUSES OF THE FACE.

BY SINCLAIR TOUSEY, A. M., M. D.,

New York,

Surgeon to St. Bartholomew's Clinic.

The use of the x ray in making examinations of the frontal sinus, the antrum, and the ethmoidal

FIG. 2.—Sphenoidal cells, anteroposterior radiograph

FIG. 1.—Antrum, anteroposterior radiograph

and sphenoidal cells divides itself, naturally, into two methods. First, that by which a lateral view

of the face is taken, and, second, an anteroposterior picture in which the tube is placed behind the head and the plate in front. This is by far the more difficult, and results are only possible, as far as the frontal sinus is concerned, with the very best obtainable apparatus and technique. In the latter case, however, it is not so much a matter of terribly powerful currents or long exposures as it is of the proper adjustment of the x ray tube and the other apparatus. The author's radiographs of this character have been made with an exposure of only thirty seconds and with a twelve inch induction coil and a primary current of eighteen amperes.

The lateral radiographs are much easier, because there is only a small fraction of the amount of tissue to be penetrated by the x ray. An exposure of fifteen seconds with a primary current of eighteen amperes is amply sufficient. The distance from the tube to the plate has a great deal to do with the success of the radiograph in either case. The anticathode should be twenty-five inches from the plate for an anteroposterior picture, and about seventeen inches in making a lateral picture.

The author has made two kinds of radiographs of the pneumatic sinuses; one set has been made from an empty skull in which the different air spaces have been filled with lead shot, which is entirely opaque to the x ray, and the other set of radiographs shows the condition of these air spaces in living patients. The radiographs of the air spaces in the empty skull furnish a set of accurate charts showing the topography of the sinuses in x ray pictures of the head. The author has found them valuable in the exact localization of disease

<sup>1</sup>A series of radiographs illustrating this subject were exhibited at a meeting of the Section in Laryngology and Rhinology, New York Academy of Medicine, December 15, 1907.

FIG. 3.—Sphenoidal cells, lateral radiograph.

and sometimes in distinguishing a shadow due to pus or a solid substance in one of these sinuses from the normal shadows due to neighboring bony structures. The radiographs of living patients have proved a valuable means of diagnosis, and it can be confidently stated that this method has great advantages over ordinary transillumination.

The anteroposterior radiograph (Fig. 1), showing the antrum full of shot, gives the comparative appearance of the side on which the antrum is empty and that on which it is full of the opaque substance. It enables us to recognize the normal location of the antrum in patients. The same picture shows the frontal sinus, which in this skull was a small unilocular air space on one side of the median line, not reaching over the orbit to any extent. The alæ of the sphenoid bone may be seen forming the upper wall of the orbits; and the bony septum of the nose and the turbinated bones form distinctive landmarks. All the bony outlines are more distinct than in the actual patient, but, as will be seen later, different portions in pictures of natural patients can be recognized.

The lateral radiograph of the antrum full of shot shows the size and position of this air space, and it also shows the frontal sinus in profile, showing the separation between the external and internal bony walls of this cavity. The malar bone sometimes forms an important landmark in such a picture.

The anteroposterior radiograph (Fig. 2) of the sphenoidal cells

filled with lead is valuable because it enables us to recognize at a glance in a similar picture from a living patient the position of these particular cells.

The lateral radiograph (Fig. 3) of the sphenoidal cells filled with shot is especially valuable as a topographical chart. There are certain shadows in radiographs of the living patient in this region which it is important to distinguish between—those due to bony structures and those due to a collection of pus in the sphenoidal cells. By comparing a lateral radiograph of a patient's head with this experimental radiograph it has been found easy to make this distinction at a glance.

Radiographs of the anterior middle and posterior ethmoidal cells, respectively, have been made upon an empty skull in which these different air spaces have been filled

with shot. The pictures are anteroposterior and also lateral. They furnish valuable information as to the exact position of these different cells.

#### *Radiographs of the Pneumatic Sinuses in Actual Patients.*

One of these radiographs (Fig. 4) is that of a patient in whom the antrum and the other pneumatic sinuses proved to be normal. It is an anteroposterior picture made with the tube behind the head and the plate in front. It shows a large frontal sinus with a number of septa. It shows the

FIG. 4.—Normal anteroposterior radiograph. *a*, frontal sinus; *b* and *d*, ethmoidal cells; *c* and *e*, antrum.

FIG. 5. Lateral radiograph. *a*, frontal sinus; *b*, ethmoid cells; *c*, antrum opaque from chronic suppurative otitis media.

ethmoidal cells somewhat more distinctly on one side than on the other. This is due to the difficulty experienced in producing an absolutely median application of the x ray.

Another picture is an anteroposterior radiograph of a patient referred to me by Dr. Alleman. The left antrum shows as a completely opaque mass, contrasting sharply with the normal air space on the right side. This picture was made with the x ray tube at a lower level than would be suitable for radiography of the frontal sinus, and the latter air space therefore does not show in the radiograph.

Another lateral radiograph (Fig. 5) is that of a distinguished physician, who had all of his upper teeth extracted for pain, and upon whom subsequent minor operations were performed for the abstraction of spicula of bone from the jaw. All these treatments failed to relieve his suffering, and he was unable to wear a set of artificial teeth for more than an hour at a time. The radiograph showed that the antrum was absolutely opaque, and an operation was performed by Dr. Cryer, resulting in a complete cure. The antrum in

this case was full of pus and swollen mucous membrane.

Fig. 6 is an anteroposterior radiograph of a case referred to the author by Dr. Joseph Abraham. It shows the frontal sinus in normal condition, but the left ethmoidal cells are opaque. The left antrum presents a small translucent area at its centre surrounded by a zone of opacity. This is the appearance to be expected in cases of suppuration in the antrum, where the pus has been evacuated, but where the mucous membrane is still swollen and unhealthy.

Fig. 7 was made of a patient of Dr. Gleitsman before operation. It shows a frontal sinus with a little less than the normal translucency, but still with an outline and sæpta which are readily seen. The mucous membrane may be swollen, but the radiograph does not show the opacity which would be found if the sinus were full of pus. The ethmoid cells do not show opacity, and the antrum presents a clear centre with surrounding moderate opacity. This also indicates a polypoid mass or swollen mucous membrane, not the presence of a mass of undrained pus.

Disease of the frontal sinus may show itself as opacity in one or more of the spaces into which the sæpta divide this cavity, and in some cases it may even look as if the frontal sinus was absent upon one side.

A case which the author examined for Dr. Phillips showed a great area of opacity, extending out to the side of the forehead, and upon operation the frontal sinus upon this side was found to contain a very large amount of pus.

#### *Examination of the Radiographs.*

Anteroposterior pictures of the head seldom show as well in the print as they do in the original plate or negative, and the best means of studying the latter is by transmitted light in a negative ex-

FIG. 6. Anteroposterior radiograph. *a*, frontal sinus; *b*, ethmoid cells; *c*, antrum showing opacity at center, surrounded by zone of translucency.

aming box. Details may be readily discovered in this way which are entirely lost in the process of reproduction as seen in the prints illustrating this article.

The frontal sinus has been shown by Cryer's *Anatomical Studies* and by the radiographs of

Some one describes one organ of the body thus: "The human eye is the most wonderful piece of mechanism in the world. It has eight hundred distinct contrivances. It opens and closes automatically its curtains thirty thousand times a day. It is selfadjusting to all degrees of light from mid-

Caldwell and Coakley to present a great diversity in size, shape, and position and in the number of sæpta which subdivide it. It follows, therefore, that the diagnosis of disease cannot be based merely upon a deviation from any particular appearance which might be considered typical. The radiograph must show sufficient detail to afford proof in itself of an abnormal condition.

## THE RELATION OF MENTAL ATTITUDE TO BODILY FUNCTION.\*

By W. L. CONKLIN, M. D.,

Jackson Health Resort, Dansville, N. Y.

Of the many complex problems which have challenged the reasoning powers of man, and sometimes baffled his best efforts, man himself is the most complex, the most difficult of solution. A great grammarian is said to have remarked that if he had his life to live over again he would spend it in the study of the dative case. If there are such possibilities for study and research hidden away in one leaf of the science of man's language, it is little wonder that a lifetime may be spent in the study of man himself without a complete solution of the problem which he presents.

The anatomist and physiologist study the structure and function of the various organs of the human body, and for 3,000 years there has been increasing evidence that David was right when he said, "I am fearfully and wonderfully made."

day to midnight. Its retina is a highly sensitive plate. Its lenses are normally perfect, with microscopic power to see the point of a cambric needle, and telescopic power to gaze upon the sun, ninety-five millions of miles away, and it is the mirror of an inward occupant. It can flash with the fire of anger, burn with enthusiasm, melt with tenderness, stare with fright, leer with villainy, twinkle with mirth, or beam with love."

While the eye is an optical instrument of such marvelous construction and power, it is but the servant of the mind, obeying the behests of volition and giving expression to emotion. Without its aid, moreover, intellect may grapple with the great problems of life, and imagination "give to airy nothing a local habitation and a name."

But while the psychologist, the anatomist, and the physiologist pursue their investigations, the physician must study man as man, not body alone or mind alone, but a complex being. He must take carefully into account this twofold nature, and I think there are but few who will dissent from the assertion that he must go further than this, even, and recognize a third factor in the problem of human life. Call it spirit, if you will; a something at least which transcends the mind in its ordinary workings as the mind transcends the body. A something of which it has been said:

"Birthless and deathless and changeless remaineth the spirit forever;

Death has not touched it at all, dead though the house of it seems."

I am aware that it may be objected that this is a realm beyond the ken of scientific investigation. This may, to some extent, be true, but it has, nev-

\*Read at the annual meeting of the Medical Society of the County of Monroe, Rochester, N. Y., December 17, 1907.

ertheless, its bearing upon the complex problem which confronts the physician—the problem which he must work out many times over in his efforts to guide back to normal, healthful activity the man or woman who is "out of commission" because of disease in some of its many manifestations.

Whether we believe in the identity of mind and matter or not; whether we assert with the materialist that everything, from a dissertation to a diatom, is the result of a "fortuitous concourse of atoms," or dissent from the assertion, or even if for the moment we dismiss the subject with the humorist's cogitation:

"What is mind?—no matter.

What is matter?—never mind,"

we must still look upon mind and body as so closely related, so intimately associated, that a condition of health and activity in one tends to produce a like condition in the other; while if one is in a marked degree abnormal the other is almost sure to suffer in one or more of its functions. The exceptions to this rule, in which there is associated with a weakened and diseased body a mind of unusual power and scope, are rare and suggestive of the innate superiority of mind over matter.

Alienists have long found abundant evidence that abnormal physical conditions are capable of producing mental disease. Indeed, the general practitioner has learned that mince pie and melancholia not infrequently bear the close relationship of cause and effect. But do we place sufficient emphasis upon the correlative truth that mental attitude and bodily function bear to each other a relationship quite as close?

I will not weary you with illustrations of this intimate association. Medical literature abounds in them, and indeed they are frequently brought to the attention of every physician. The medical student is very likely, early in his career, to observe the effect of imagination upon his own bodily functions as he suffers a sudden twinge of pain on the McBurney's point side of his anatomy just after a lecture on appendicitis, or finds himself consulting the long suffering professor of practice the day following a lucid description of valvular diseases of the heart.

Fiske quotes from the *Spectator* of March 29, 1710, a humorous account of the effect upon the writer of the perusal of medical books: He said that as a result "he found his pulse irregular, and scarce ever read the account of any disease that he did not fancy himself afflicted with. Dr. Sydenham's learned treatise on fevers threw him into a lingering hectic, which hung upon him all the while he was reading that excellent piece. I then," he continues, "applied myself to the study of several authors who have written upon phthisical distempers, and by that means fell into a consumption, till at length, growing very fat, I was, in a manner, shamed out of that imagination. Not long after thus I found in myself all the symptoms of the gout (except pain, but was cured of it by a treatise upon the gravel, written by a very ingenious author, who (as it is usual to convert one distemper into another) eased me of the gout by giving me the stone."

If the imagination produced only temporary functional disturbances its effects would be of lit-

tle importance, but there can be no doubt that long continued interference with function, and even organic changes sometimes result.

Dr. J. M. Buckley says that "so long ago as the time of John Hunter it was established by a variety of experiments and by his own experience that concentration of attention upon any part of the human system affected first the sensations, then produced a change in the circulation, next a modification of nutrition, and finally a change in structure."

Not only has the imagination a powerful influence over sensation and organic function, both voluntary and involuntary, but the intellect, the emotions and the will have, or may have, an influence quite as potent.

Indeed is it not true that thought, either conscious or unconscious, precedes and gives direction and character to bodily function?

There may be no immediate result growing out of disregard, first in thought, then in act, of the laws of health, but sooner or later so called involuntary bodily functions will suffer as a consequence.

The title of a recent book, *Why the Mind has a Body*, suggests an important truth of which we sometimes lose sight, namely, that the intangible something, which for want of a better name we call mind and spirit, is deserving of first and most important place in all our estimates of man as man.

I am not in the least in sympathy with Mrs. Eddy and the so called Christian science principles which she so zealously advocates. Indeed, it has always seemed to me that her teachings contained little of Christianity and less of science and have resulted in incalculable harm. The same indictment might be brought against the "new thoughts" in general. If a little knowledge is a dangerous thing and the danger is in proportion to the littleness of the knowledge manifested, then they are indeed a dangerous company. Truth must be considered in its relationship to other truths, and with due regard to its relative importance, otherwise it may be so distorted and overworked as to lose its fair character and pose as a legitimate offspring of the father of lies himself.

It is profoundly true that mental attitude has much to do with bodily function and is capable of producing changes in nutrition and secretion. We may go a step farther and say that healthful and hopeful habits of thought do much to put the body on the defensive against the assaults of disease, but to give absent treatment instead of antitoxine to a case of diphtheria or to treat cancer with the assurance that all is well, is fanatical, if not homicidal.

No one will deny the superiority of mind over matter. No one will gainsay the assertion that mind and spirit are or should be the controlling elements in the makeup of any human being. But to ignore, in our present state of existence, the physical in man is to cast reason and common sense to the winds and substitute an idealism, the adoption of which leads to results and conditions which are anything but ideal.

Having made clear, as I hope, my position in regard to the so called "new thoughts" in general, and the so called Christian scientists in particular, I beg to assert the belief that as physicians we give

too little attention to the subject of psychotherapy. I do not refer to the employment of hypnotic suggestion, which, it seems to me, has a very limited field of usefulness as a therapeutic resource, but to the practical application of the plain, common sense fact that right thinking, a normal, healthful mental state or attitude, is conducive to continued bodily health and a potent remedial agent when bodily health is below the normal standard. I wish to place emphasis on the fact that just as *bodily* attitude does not mean the position of the head or an arm, but of the body as a whole, so *mental* attitude refers, not to the will or the emotions, but to the mind in its entirety. What is the trend of a man's thought? Can he use his intellect and as a rule reach conclusions which are definite and reasonable? Are his emotions and imagination under control and is his volition strong? Has he an object in life and some sense of personal responsibility or is he aimlessly drifting? These are questions which have a distinct bearing upon the bodily function and health of any individual. No doubt the subject has been brought into disrepute through the mistaken zeal of faddists, but the scientific man should not be prejudiced against or fail to recognize the importance of truth simply because it has been distorted and mixed up with error.

The alienist would be but poorly equipped for the treatment of diseases of the mind if he had no knowledge of the structure and function of the bodily organs. Is it not equally important that the physician in general practice should be conversant with the phenomena of normal and abnormal mental processes and their relationship to bodily function? To this end it would seem that psychology and psychotherapy should be given a place in the curriculum of our medical colleges.

An intelligent recognition and application of the principles involved in the relationship of mind and body is, I am convinced, of great value in the scientific treatment of disease. It is not so easy as to prescribe veronal and valerian, but more lasting results may be looked for. Moreover, the patient who has been taught something regarding the importance of mental attitude in its relationship to health will be less in danger of a repetition of his present painful experience, and preventive measures must always be regarded, both from a scientific and from a philanthropic standpoint, a long step in advance of those which are palliative or curative only.

#### BACTERIAL VACCINES OF STAPHYLOCOCCI STAINS, A TECHNIQUE FOR THEIR PREPARATIONS.\*

BY HARLAN SHOEMAKER, A. B., M. D.,  
Philadelphia.

I have been enabled to make the following observations while at work on the immunization of cases of furunculosis, acne, and sycosis in Professor J. F. Schamberg's clinic for diseases of the skin held at the Polyclinic Hospital. The work has been done in the laboratories attached to the hospital with the kind permission of the registrar, Miss Kirkbride.

The experimental evidence of phagocytosis by Metchnikoff and of bacteriolysis by Pfeiffer as a chain in the mechanism of immunity has been elaborated by the French and German schools; and Wright and his followers have placed the former theory well before the profession.

It is my pleasure to bring before this society for discussion a statement, as to the effects produced by the application of heat upon the bacterial body, as to degree of intensity, duration of exposure, and the relation this bears to the immunity conferred by inoculations of bacterial suspensions so prepared.

A number of the workers in this country and abroad have dismissed this subject with a word. They allege that their bacterial suspensions are "killed cultures" rendered incapable of further propagation.

Sir Almoth E. Wright (*Lancet*, 1902) first killed his cultures at 149° F. for twenty minutes. One patient, of a series of six reported in this paper, developed a localized inflammatory reaction at the point of inoculation. Wright asserts that this result occurred from staphylococcal matter already in the system of the patient, while all six patients showed evidence of pronounced local reaction, as well as constitutional symptoms. Subsequently Wright (*Proceedings of the Royal Society of London*, July 26, 1904, p. 154) evidently found it necessary to keep the suspension of bacteria in the incubator twenty-four hours after heating at 140° F. for thirty minutes. The suspension is then cultured and at the same time enumerated. Twenty-five to seventy-five million bacteria are used. Should the culture media show evidence of bacterial growth, the technique is repeated until the organisms have lost their power of further multiplication.

E. H. Schordor, of the Rockefeller Institute, makes a reference to the use of killed cultures of streptococci, employing twenty-five to one hundred million in number. Dr. Simon, of Baltimore (*Experimental Medicine*, September 21, 1907), in a paper read before the Association of American Physicians last assembled in Washington, D. C., makes the most remarkable statement that he can see no difference in the reaction of a patient to his vaccine whether twenty-five million or a million million staphylococci are given. And Wright and Reed, when employing the colon bacillus for immunization in cases of cystitis, make use of a sterilized vaccine containing two hundred million organisms.

Since we find such a variety of ideas and conclusions among the workers, apparently the elaborate experiments in immunity present the only analogy to the effects of heat on a bacterial body. Here one is confronted by a great diversity of terminology, and finds, on the other hand, a marvellous unanimity of results.

Regarding the various theories elaborated from the standpoint of temperature alone, there has been found in the blood a thermostabile substance at 140° F., and a thermolabile substance at the same temperature. Ehrlich and the German school express an amboceptor stable at 140° F., and a complement labile at 140° F. Bordet and the French school designate their thermostabile and ther-

molabile products as *fixateur* and *substance sensibilisatrice* respectively.

Bordet (*Annales de l'Institut Pasteur*, xii, 10) has recently shown the analogy between hæmolysins and bacteriolysins. Both substances are thermolabile, and if they be destroyed by heat the serum will still be found to contain a thermostable substance, which has the power of agglutinating either the blood corpuscles or the bacteria as the case may be. This substance of a thermostable nature in the serum he terms a *fixateur*.

Wright and his followers determine an incitor stable at 140° F. and an opsonin labile at the same temperature. Wright (*Proceedings of the Royal Society of London*, lxxvii, Series B) invents the term incitor to explain the phenomena of phagocytosis of bacteria by washed leucocytes in the presence of blood serum which has been heated for ten minutes at 140° F. Although the opsonin has been removed from the serum by heating, there yet remains a substance of a thermostable quality which unites with the bodies of the bacteria. They are rendered capable of phagocytosis by the incitor without the presence of opsonin or any other thermolabile product in the serum. Wright does not admit the presence of any new body in the blood serum, notwithstanding his use of the term incitor, and alleges that the thermostable substance does not exist, there being instead but an opsonin attenuated by heat, thereby disproving any possibility of spontaneous phagocytosis.

Dean (*Proceedings of the Royal Society of London*, July 8, 1905, Series B) produced an active phagocytosis of bacteria specially treated, in which the presence of an immune serum was displaced by a physiological salt solution. The bacteria used in the experiment were centrifuged through a heated immune serum, and thoroughly washed free of the serum before being used. It was found that the organisms selected something from the immune serum which rendered them capable of being engulfed by the white blood cell. This serum is quite incapable of producing phagocytosis in the usual way with the species of bacteria used, although it is active in opsonizing any other species of bacteria.

Two years later Cowie and Chapin (*Journal of Medical Research*, xii, No. 1, 1907), in experiments similar to those of Dean, and independent of any knowledge of his work, arrived at the same conclusions, and Wright (*Lancet*, November 2, 1907) adds a beautiful confirmatory analogy to this work when he demonstrates the difference between the opsonic power in the normal blood serum and in the serum obtained from the toxins of infection. The latter is very deficient in opsonin.

Regardless of the attempts of the German school to explain immunity by a multiplicity and specificity of each *Antiseptin* and *Complement*, or those of the French school to confine all serum reactions to a duplicate role, the various experiments conform alike to heat exposures. Wright does not accept this, although he readily admits the stabilization of the blood serum by heat, while, confused by the variety of their terminology, his technique in the hands of competent observers in this country

and abroad shows opsonin to hold the same relations to temperature as those which are expressed in their experiments.

	Substances in blood serum thermostable at 140° F.	Substances in blood serum thermolabile at 140° F.
Ehrlich and the German school .....	amboceptor	complement
Bordet and the French school .....	fixateur	substance sensibilisatrice
Wright and the English school .....	incitor	opsonin

#### Summary of Observations.

- (a) Opsonin in the serum is modified by heat.
  - (b) Bacteria are incited to phagocytosis by serum from which the opsonin has been removed by heat.
  - (c) Bacteria unite with a substance in heated serum which prepares them for phagocytosis.
  - (d) Bacteria remove a substance from the serum collected at the foci of infection which reduces the opsonizing power of this serum for this species and no other below that of the patient's blood serum.
- These observations deduced from actual experimentation do not prove the presence of a thermostable and a thermolabile substance in the bacterial body, but they suggest it. The bacterial body differs from the blood serum, perhaps, in the molecular arrangement of its elements and in its inherent ability to reproduce itself. This difference presents a step from an unorganized organic substance in the serum toward an organized organic substance in the bacteria.

In the spring of 1907 Gildersleeve, of the University of Pennsylvania, successfully inoculated two cases of syphilis in the clinic. Both patients had constitutional and well marked local reactions. An abscess developed at the site of inoculation in the second case, while only a cellulitis appeared upon incision of the local tumefaction in the first case. Both patients recovered completely from the syphilis.

When I first prepared a vaccine, taking 176° F. as the thermal death point of the staphylococcic strains, the constitutional reaction upon inoculation was mild. No local reaction occurred at the site of injection, and very little activity was demonstrable by Wright's method of estimating the phagocytic power of the blood. In all sixteen cases were determined. In these the failure of Wright's method to yield results was attributed to poor technique and insufficient experience.

Subsequently, during the preparation of a vaccine for the use of the clinic, the water bath in which the cultures were killed attained a temperature of 104° F. One of the vaccines in this brew was used upon a physician suffering with furunculosis. Forty million staphylococci at 176° F. had caused him some symptoms of constitutional reaction, such as thirst and restlessness at night, accompanied by irregular fluctuations in the opsonic index; 0.75 to 1.3 were noted. If previous inoculations of bacterial suspensions prepared at 176° F. were as significant and but mildly effective, one at 104° F. would do no harm. This vaccine contained ten hundred million staphylococci. According to the patient, who was a conscientious observer, this in-

oculation produced no more clinical effect than the injection of so much coagulated egg albumen; neither did the opsonic index fluctuate, but remained at 0.8.

This shows how it might be possible for Dr. Simon, or any one for that matter, to give in a suspension a million million bacteria, subcutaneously inoculated, without untoward effect.

Now began a gradual reduction in the temperature applied to the water bath. The inoculation of a bacterial suspension, heated at 158° F. for one half hour, gave evidence of fluctuation in the phagocytic index; at 149° F. for half an hour, produced more pronounced constitutional symptoms; at 140° F. the cultures had to be maintained in the water bath one hour before the thermal death point inhibiting the reproduction of the species was reached. Upon inoculation with this suspension a violent constitutional reaction was observed. Three strong men who had received injections not only felt feverish and restless the next day, but remained in bed more or less prostrated. Only a few phagocytic counts were made in these cases. They showed that the positive and negative phases in Wright's experiments were well marked by a fluctuation from 0.5 to 3.5, 1.0 being the normal or control index.

We see that the clinical reaction and laboratory phenomena exhibit an increased intensity as the temperature applied to the bacterial suspensions is reduced. The duration of the application of heat is also an element to be considered.

Further reduction of the temperature to 138.2° F. and then to 136.4° F., used in the preparation of the vaccines, was followed by disastrous results. Five people were unconsciously inoculated with living cultures of bacteria, of autogenous strains, twenty to forty million strong, pasteurized for one hour at 136.4° F. All were attacked with a local tumefaction of brawny induration, with a sensation of deep fluctuation in each case. In three of these cases the local reaction disappeared, while two patients were attacked with an abscess at the site of inoculation. One of the latter showed a pronounced rise and then a depression of the phagocytic count; the other, at two different readings of several days' interval, exhibited a continued depression of the phagocytic power of the blood. A third patient of this series, having relapsed clinically, was reinoculated with a bacterial suspension treated in a water bath for one hour to 138.2° F. A small abscess developed at the site of injection. One reading subsequent to the evacuation of the abscess showed a very high index. From all three patients there was recovered the same organism which had been introduced.

The following is a technique recommended for the purpose of producing the highest "positive phase" of Wright: Prepare, 1, sterilized glass pipettes; 2, sterilized test tubes, each containing small glass beads or sand; 3, a twenty-four hour culture of bacteria of autogenous strain (not necessarily a pure strain) on a nutrient agar slant; 4, a sterile salt solution, 0.85 per cent., sodium chloride; 5, a water bath; and, 6, a thermometer.

With a sterile gum attached to the pipette, draw

up about 1 c.c. of the salt solution. This solution is played over the surface of the agar slant culture media until the twenty-four hour old growth of bacteria has been washed free from its surface.

The bacterial suspension is then drawn up into the pipette and immediately transferred to the test tube containing the glass beads. The tube is now stoppered with its cotton plug and agitated freely in order to disintegrate the colonies and clumps of bacteria. Having previously heated the water bath to the desired temperature the bacterial suspension is inserted into it. The surface of the water in the bath should be above that of the salt solution containing the suspended bacteria, or, better still, if the vaccine is sealed in a glass receptacle, complete submersion in the bath is desirable. The thermometer should be kept in the bath under the same relative conditions as those surrounding the bacteria. For example, the bacteria being in a certain quantity of solution in a test tube, the thermometer should also be similarly placed. Both tubes should then be kept in the closest contact in the water bath. A temperature of 136.4° F. to 138.2° F., or the lowest possible point required to destroy the reproductive activity of the germ, is maintained for one hour. It is then subcultured and enumerated, when the suspensions are placed in the incubator at 98.6° F. for the remaining twenty-three hours. Prior to a repetition of this technique, which is advised for at least three successive days, a daily subculture following the pasteurization is made from the bacterial suspension. If at the end of the fourth day there is no growth upon the subcultures, and especially the last one, the vaccine may be used for subcutaneous inoculation.

A suspension containing five to ten million of bacteria, prepared at this low temperature, is equal to a four hundred million bacterial suspension prepared at a higher temperature.

At some point, between the temperature necessary for greatest bacterial growth and that for reproductive death of the germ, lies a substance which is active in producing immunity. This substance may be entirely inactivated by heat, or it may evidence marked activity just above the degree of temperature where the reproductive powers of the organisms cease.

The ultimate chemistry of the proteid body remains for the future. Our object is a bacterial product of efficiency which may be injected with impunity. Perhaps this problem may best be solved without heat at all. Digestion by an active ferment and precipitation of the globulins, albumoses, and other cleavage products of the bacterial body will help to elucidate this subject. (Holliburton, *Proceedings of the Pathological Society of London*, lvi, p. 158, 1905.)

When we consider that every surgical wound made for the relief of infected parts gives rise to inoculation of living bacteria and their products, uncontrolled and unlimited; that every massage, active or passive, of diseased areas produces much the same result with absorption of fixed tissue cells and tissue juices in addition, there may be some extenuation for these unusual experiments.

### Conclusions.

A thermolabile and a thermostabile substance is found in the bodies of the staphylococcic strains of bacteria, which substances, in the organic bacterial bodies, are of the nature of an amboceptor and a complement.

The activity of the thermolabile moiety of the bacterial body varies, inversely, as the degree of heat and its time of application.

## THE INFLUENCE OF ANIMAL THERAPY UPON THE OPSONIC INDEX IN TUBERCULOSIS.

BY GILLIFORD B. SWEENEY, M. D.,  
Pittsburgh, Pa.,

Formerly of the Pasteur Institute, Paris.

In an article recently published in the *New York Medical Journal*<sup>1</sup> the clinical results obtained in tuberculous patients, following the administration of a lymph derived from the bullock, which had previously been rendered immune to tuberculosis, were described.

It is the purpose of this paper to briefly describe the influence of this treatment upon the opsonic index.

While Wright, Metchnikoff, Ehrlich, Neufeld, and other scientists differ in their opinions as to the sources whence the defensive properties of the blood are derived, upon this point they all agree, that phagocytic activity follows any manifestly stimulating influence, however exerted, upon the blood. Also that the ability to withstand or overcome infectious processes is proportionate to the degree of this activity.

We shall not describe the technique of obtaining the opsonic index, as this is available in the literature.

The following five cases were carefully selected from a larger list of fifty-two patients treated, in which systematic observations of opsonic indices were recorded every thirty days. All the cases described are among those in which tuberculous bacilli were found in one or more of the secretions.

CASE I.—Male, aged twenty-two years, bookkeeper by profession. After losing in weight and vigor for four months applied for treatment. Patient was very anæmic. Temperature in morning subnormal, in evening 99.5° to 100.5° F. Respiration was shallow and hurried. There was a moderate cough, with mucopurulent expectoration. Pleuritic pains were present upon left side of thorax. Marked dullness over upper lobe of left lung, with moist râles. Right lung was not perceptibly involved. Tubercle bacilli were found in sputum. Opsonic index 0.76. Patient had to minims antituberculous lymph daily, omitting every seventh day for thirty days. At the end of that time morning temperature was very slightly subnormal or normal. Evening temperature did not exceed 99.5°. Opsonic index 0.84. Decrease in amount of expectoration and number of bacilli present. Anæmia was less marked, and general nutrition was much improved. Opsonic readings at the end of sixty and ninety days' treatment showed 0.91 and 0.97 respectively, with corresponding improvement in all symptoms. A fourth month's treatment was administered, the evening index at termination at 0.99. Patient was allowed to return to work as an indicator for his firm, spending most of time out of doors. Observation made sixty days later showed opsonic index still 0.97. General condition of patient was very good.

CASE II.—Married woman, age twenty-six years. Brother

died at same age of phthisis florida. Patient had diarrhœa with severe abdominal pains. Mesenteric glands were perceptibly enlarged. Tubercle bacilli were abundant in feces. There was no perceptible pulmonary involvement. Temperature varied from subnormal morning to 101° F. evening. Pulse 95 to 110. Patient suffered from insomnia. Appetite was capricious. During three months indisposition patient lost fifteen pounds. Opsonic index 0.82.

Daily injections of antituberculous lymph were used for three months. A normal temperature was gradually approximated and maintained after two months' treatment. Diarrhœa disappeared entirely before the end of treatment, decreasing doses of Epsom salts being administered daily until dose was infinitely small, and then discontinued. Opsonic index at end of first month was 0.95. Second reading one month later showed 1.02. Final observation made immediately after treatment was discontinued showed opsonic index 0.985. Later observation could not be made owing to patient's moving to a neighboring state, but she reported continued improvement.

CASE III.—Patient was a boy, seventeen years old. Several members of his mother's family had died of pulmonary phthisis. Patient applied for treatment for "chronic sore throat." Voice was clear and full, left tonsil much enlarged, with ulcer covering one fourth its surface. Cervical lymphatics were enlarged, especially on left side. Patient complained of pain under sternum, during deep inspiration. There was diffused infiltration over both upper lobes. Expectoration was scanty and showed no tubercle bacilli. The tonsillar ulcer was curetted and examination showed tubercle bacilli in large numbers. This boy had lost probably ten pounds in weight. Temperature readings showed slight evening rise. Opsonic index 0.89.

Antituberculous lymph administered for three months. Tonsillar ulcer treated with x ray through a tube. The cervical glands, as well as anterior aspect of the thorax, were also rayed every third day during first half of treatment. At the end of this time the tuberculous ulcer had entirely disappeared and the patient complained of no pharyngeal or other discomfort. Improvement in vigor and weight was gradual but continuous. Opsonic readings at end of each month's treatment showed 0.95, 0.92, and 0.985 respectively. Observation made two months later showed 0.975. Patient's condition is seemingly normal.

CASE IV.—Patient, single woman, thirty-three years of age, of distinctly anæmic type, presented herself for treatment, complaining of extreme bodily weakness. There was a marked hepatization of upper half of left lung, with scanty expectoration, showing limited number of tubercle bacilli. Temperature seldom subnormal and frequently running 103° in the evening, with rapid pulse. Opsonic index 0.68.

Antituberculous lymph was administered for four months, 10 minims daily, omitting every seventh day. Collateral treatment, which seemed suited to the exigencies of the case, was also instituted. This case is of interest chiefly because at no time during treatment did there seem to be the slightest improvement. The temperature was not reduced and the opsonic index readings remained practically the same for some time, while the lung involvement and emaciation increased. At the present time, two months since treatment was discontinued, the patient is bedfast and failing rapidly.

CASE V.—Patient was a bright boy of fifteen years. Tuberculosis of hip joint, following similar attack four years previous, involving the same joint. Temperature, pain, and swelling were characteristic. Pus from a discharging sinus contained tubercle bacilli in abundance. Temperature was slightly above normal. Opsonic index 0.92. No appreciable lung involvement. An extension apparatus was applied, patient being confined to bed for four weeks, after which he was allowed to go about, continuing to wear the regulation apparatus during the three months that antituberculous lymph was administered. The result in this case was dramatic. The opsonic index at the end of first month was 0.975. One month later 1.2, and at the end of third month 0.985. The patient was the possessor of a voracious appetite, which it was next to impossible to satisfy or control. Three months have elapsed since treatment was discontinued. Patient walks with a cane without apparent discomfort. The sinus has entirely closed, and patient has gained perceptibly in weight.

For my own part I am strongly disposed to attribute the benefits observed in these cases as much

<sup>1</sup>Animal Therapy in Tuberculosis. *New York Medical Journal*, December, 1906.

to the invigorating influence of the lymph upon the phagocytes as to its specific antitoxic action upon the tuberculous bacilli.

In my monograph<sup>1</sup> upon this subject, among other preliminary propositions laid down, is the following: "Tuberculous infection takes place in the human subject only when the normal ratio of resistance is lacking or disturbed." I am fully convinced that a defensive attitude upon the part of the human organism towards infectious agents can be established and maintained only through influences exerted upon the living, active cell. It is true that this view of the subject has not been particularly popular during the past year. It will be interesting to the reader to know the present attitude of Professor Metchnikoff, the leading exponent of the doctrine of phagocytic defense, upon the subject. In a personal letter, received very recently, he writes:

"I see no reason for modifying my views upon this subject, as expressed in my essay upon *Hygiene of the Tissues*.<sup>2</sup> There can be no doubt that, under artificial conditions and outside the body, the phagocytes are weakened, and cannot show their functional activity to such advantage as inside the body. It is therefore quite natural that under such unfavorable conditions the phagocytes more readily attack the microbes already impregnated with preparatory substances than the quite intact microbes. When they have been deprived of this favoring influence the phagocytes can only fulfil their duties with more or less delay. That is exactly, in reality, what takes place. Left to themselves in a liquid, deprived of all opsonic substances, the phagocytes nevertheless surround the microbes; only instead of doing this in a quarter of an hour, it takes them longer, perhaps an hour to two. In the experiments conducted by Dr. Löhlein, of Leipzig, who was at that time working in my laboratory, it was proved that the absorption of the bacilli by the phagocytes often occurred quite as early in normal saline solution as in the sera, and thus the importance of the opsonins is still further diminished. I do not wish, however, to depreciate the utility of the opsonic index in determining the defensive resources of the blood. For this purpose it is invaluable, and it is to be deplored that the difficulties encountered in rendering it available to the general profession are so great."

I wish to express my thanks to Dr. Edward T. Smith, of Buffalo, N. Y.; Dr. H. G. Walcott, of Dallas, Tex., and Dr. T. E. Courtney, of Indianapolis, Ind., who rendered me valuable assistance in making systematic observations upon the work which I have briefly described above.

519 SMITH BLOCK.

## THE NEWER METHODS OF EXAMINING THE BLADDER.\*

BY FREDERIC BIERHOFF, M. D.,  
New York,

Attending Surgeon, Urological Department, German Dispensary; Attending Surgeon, Department of Genito-urinary Diseases, West Side German Dispensary; Fellow, New York Academy of Medicine; Corresponding Member of l'Association Française d'Urologie.

The methods of examination of the bladder which are at our disposal are: Inspection, percussion, palpation, exploration with the sound, exploration with the catheter, digital exploration, exploratory incision, examination by the x ray, and examination by direct illumination.

Of these methods all, with the exception of inspection, are of doubtful value. In the treatment of the bladder, the only method of examination which is of value is the x ray. The x ray is the only method of examination which is of value. The x ray is the only method of examination which is of value.

examination by the x ray and examination by direct illumination, have been in use for a great many years, and give us comparatively little, and usually unsatisfactory, information concerning diseases of the bladder. The last two mentioned are the more modern developments in the line of bladder examination, and of these examination by direct illumination, by means of the cystoscope, is the most exact and most satisfying. Each, however, of the methods enumerated gives us some information, and in order that none may be slighted I shall take them up in the order named.

**Inspection.**—This gives us no further information than to allow us to know at times—in thin individuals, that the bladder is distended. Under such circumstances we may, when the bladder is full, notice the elliptical or oval prominence in the hypogastric region, which reveals to us the presence of a distended bladder.

**Percussion.**—This method makes it possible for us to determine the degree of distention of the bladder by revealing to us the presence of an area of dullness in the hypogastric region. It is not positive either. Intestines, distended with gas, may overlie the bladder and interfere with the perception of dullness, or, if distended with feces, may simulate a distended bladder.

**Palpation.**—Palpation may be performed by either the simple or combined (or bimanual) method. It gives us more information than the previously mentioned methods. By the simple method, performed by the use of both hands upon the surface of the abdomen, we may make out the form of the bladder, its degree of distention, the character of the bladder wall with regard to irregularities, and its degree of sensitiveness. In thin individuals it is sometimes possible to determine the presence of calculi, if large, particularly in children. We may also, at times, diagnose the presence of pericystitis and paracystitis. It should be carried out with the patient lying upon the back, the shoulders being slightly raised, and the knees and hips flexed and properly supported. The bimanual method of palpation is carried out with the patient in the same position as for simple palpation, one hand examining the abdomen, and one or two fingers of the other hand being passed into the rectum, or vagina. This method is best carried out with an empty bladder. By means of it we may diagnose prostatic hypertrophy, hard tumors of the bladder wall, calculi, and decided infiltrations of the vesical wall. In females we may also diagnose vesicovaginal fistulae.

**Exploration with the Sound, or Sarcher.**—This examination should be carried out with the patient in the same position as in the former methods, and the bladder should contain a moderate amount of fluid. The sounds used may be either of metal, or of elastic material—rubber or silk or linen weave—covered with an elastic mass. The stone searchers are of various familiar models. It is assumed that the readers know all about the indications and contraindications for the passage of instruments, as well as the proper method of passing these. The beak of the instrument must enter into the bladder cavity, and the investigator must assure himself, before proceeding further, that it is freely movable in all directions. He may then measure the size of the bladder

by pushing forward the searcher in the middle line until it is arrested, and then noting the distance between this point and the bladder outlet. The sensibility of the bladder wall may also be noted. In some spinal diseases, notably locomotor ataxia, the vesical wall is singularly anæsthetic. In cases of ulceration it is very sensitive. The character of the bladder wall must also be noted—whether smooth, or rough, as in columnar bladder. It is also possible, with the sound or searcher, to palpate the protrusion of an enlarged prostate. Foreign bodies may be discovered by means of the sensation imparted to the instrument. It is often, but not always, possible, in cases of stone, when using a metallic instrument, to get a distinct click. When using an elastic instrument it, however, often occurs that a sensation as of the catheter's grating upon a foreign body is experienced, which, upon investigation, proves to have been due only to the spasmodic gripping of the catheter by the sphincter muscle. Experts in the use of the searcher, or lithotrite, may even determine the presence of multiple calculi by using the lithotrite and seizing the stones separately. In some children, too small for the use of the cystoscope, a small metallic catheter may be used as a searcher. The use of the sound, or searcher, leaves us entirely in the lurch in determining the presence or absence of tumors.

*Exploration with the Catheter.*—The chief use of this method is in determining the power of the bladder to fully empty itself, and in measuring the amount of residual urine. It is of value in cases of retention, suspected to be of prostatic origin, in which there is no hypertrophy palpable per rectum, and particularly in the examination of cases of suspected tabes, where, in the absence of any discoverable organic obstruction in the urethra or bladder, the patient has a large amount of residual urine, with a perfectly capable detrusor. I have been able to make the diagnosis of tabes in the early stage, in a number of instances, through the discovery of large amounts of residual urine in the absence of organic obstruction of the urethra. This diagnosis should, however, never be made without the corroboration of cystoscopy. The catheter is also of value in determining the amount of intravesical pressure.

*Digital Exploration.*—This may be of value in women. In such cases preliminary dilatation of the urethra is necessary. It is possible, by means of this method, to explore the interior of the bladder, and to determine the presence of foreign bodies or calculi, and the presence of tumors, if large. It is very unsatisfactory, however, in all cases except the determination of foreign bodies.

*Exploratory Incision.*—By means of the suprapubic incision it is possible to get a clear view of the entire interior of the bladder. Owing to the nature of the operation, however, it should never be employed until a satisfactory cystoscopic examination proves to be an impossibility.

*The X-Ray.*—It is one of the valuable methods to employ, when employed by a competent roentgenologist, the presence of foreign bodies and of calculi, in some instances. After filling the bladder with a ten per cent. bismuth sulphate solution, we are enabled to discover calculi and fibroids. It is

however, of no value in the determination of inflammatory conditions, new growths, etc.

All of these methods, however, when all is said and done, are uncertain and unsatisfactory, with the exception of the exploratory incision, and this is a procedure of so grave a nature that, as stated before, it should only be employed when all other methods fail.

*Cystoscopy.*—The certain method of examination of the bladder is, and must remain, the method of direct illumination, by means of the cystoscope, for no other method gives us so much information as this. Where any stiff instrument can be passed at all into the bladder, the cystoscope may be employed. I have examined with it children as young as four years, and I feel confident that, were the need to arise, I should be able to examine even younger children with it. While cystoscopy is not free from dangers, particularly in the hands of inexperienced or careless operators, it offers, when properly and carefully employed, the minimum of danger and the maximum of utility.

There are two methods of examination—or rather two types of instruments—those for direct vision and those for indirect. The instruments of the direct vision type are all modifications of the principle first laid down by Bozzini, who, in 1806, first proposed a method for examining the various canals of the body by means of his so called "light carrier." Of the instruments in use at the present day those of Pawlik-Kelly and Brenner, with their modifications, are the representatives of the direct method. The indirect method is that of Nitze, and the instruments employed are all modifications of Nitze's original prismatic cystoscope.

We are all sufficiently familiar with the instruments, so I may pass over the descriptions thereof, and content myself with the statement that, while the straight telescopic instruments have the advantage that they do not invert the image, they suffer from the disadvantage that there are parts of the bladder interior which cannot be seen when such instruments are used. By means of the prismatic cystoscope, however, every part of the bladder wall may be brought into the field of vision, and to the experienced cystoscopist the inversion of the image forms no obstacle whatever to correct examination and interpretation. Recently Jacoby, of Berlin, has devised an attachment which screws on to the ocular end of the cystoscope, by means of which the inverted image may be restored to its original position. In other words, the inversion is corrected. The instruments of the Pawlik-Kelly type may be dismissed with few words. Where these instruments may be used, those of either the straight vision telescopic, or the prismatic types may be employed, and whereas the Pawlik-Kelly are of utility only in the female, those of the other two classes may be employed in both sexes. The knee elbow position, also, required for the employment of the Pawlik-Kelly cystoscope, is distasteful to most patients and uncomfortable; while, by the employment of the other two types of instruments, the comfort of the patient is much more easily secured. Certainly, those families who, after having been repeatedly subjected to the Pawlik-Kelly method, have been cured by me, by

the Nitze method, have invariably expressed a great preference for the latter.

In order to successfully cystoscope a patient, whether male or female, there are several conditions which are requisite. In the first place, the operator must understand the construction of his instrument and the accidents to which it is subject. Nothing is more distressing or disturbing to both operator and patient than the frequent removal and insertion of an instrument which has met with some accident. The instrument must always be thoroughly tested, both as regards its electrical and its optical apparatus, before it is inserted into the urethra of the patient, and whatever may be at fault must be remedied. Lamps should be tested slightly beyond the limit at which they are going to be employed, in order that they may be less likely to burn out after insertion into the bladder. The electrical source also must be examined, in order that there may be no trouble with this. Either the storage battery, or the wet cell battery, or the street current, cut down to the proper strength by means of a controller, may be employed.

The urethra of the patient to be examined must allow of the easy passage of the instrument to be used at the examination. For the examination of children, the specially small cystoscope, made particularly for this purpose, should be employed. Instruments of this type may be had of a calibre as small as No. 14 Charrière, and it is a good plan for the cystoscopist to have instruments of various calibres. In the presence of stricture of the urethra, where an immediate examination is not possible with the use of the smaller sized instruments, which, of necessity, have a smaller field of vision than the larger instruments, preliminary dilatation of the stricture must, of course, be employed. The meatus may, in males, also have to be enlarged by incision. In females I have never had any difficulty in examination, as a result of obstructive urethral conditions.

Another requisite is that the bladder shall be capable of a sufficient degree of distention to make free excursion of the beak of the instrument possible. It has always been my practice to use as large an amount of filling fluid as the patient would tolerate with comfort. In males, whenever possible, I employ 300 c.c.; in females as much over that as the patient will tolerate with comfort. In infants I have had to examine with as little as 50 to 75 c.c., although one is frequently surprised at the degree of distensibility of the bladder of the infant. Opinions vary as to the minimum of fluid which may be employed with safety. I have repeatedly had to cystoscope adults with as little as 60 to 75 c.c., although I must confess that I do this with trepidation. It is a safe rule to follow that in those cases which do not tolerate at least 75 to 100 c.c. of fluid, it is wiser to postpone the cystoscopy until such a time as treatment of the bladder has made such a degree of distensibility possible. Where vesical sensitiveness is pronounced, the use of cocaine solution will frequently suffice to make safe distension possible. Only where an immediate cystoscopy is urgently indicated should one venture to cystoscope with less than 75 c.c., and then it must be done by interrupting the illumination at intervals of two to three seconds—in other words, the light is turned on for from two

to three seconds, and then at once turned off, this manoeuvre being repeated at intervals of about 10 seconds, in order that the lamp may have a chance to cool off, and cauterization of the bladder wall be avoided.

The bladder must be filled with a transparent medium, and to this end must be irrigated until the fluid used to cleanse the bladder returns perfectly clear. This is, at times, a very tedious process, and one which taxes the patience of the operator and patient to the utmost. Any bland, nonirritating fluid which is perfectly transparent may be employed, such as sterilized water, or sterilized normal saline solution, boric acid solution, oxycyanate of mercury, etc. It is a matter of great importance to have the fluid perfectly clear, for even a slight macroscopic turbidity may be just enough to render hazy the pictures seen with the cystoscope.

In cleansing the bladder, I have found it of service to note whether the fluid steadily clears, remains turbid, or clears and then suddenly again becomes turbid. If it steadily clears the operator need only persevere in the simple cleansing. Should it remain steadily turbid with blood, then it is wise, at times, to postpone the further irrigation and examination until after the employment, for a time, of a solution of adrenalin chloride. I have found this of great value in checking the hæmorrhage from vesical ulcers, or bleeding tumors. Where the fluid clears temporarily and then again becomes turbid, with either pus or blood, we are almost certain to have to deal with a suppurative, or bleeding process, of renal origin. In cases of this sort I have repeatedly had to examine with slightly turbid fluid. In such cases it has been my custom to cleanse, as far as possible, and when the fluid returned relatively clear, to insert the cystoscope and examine only the ureteral orifices at that sitting. At a later sitting the examination may be completed.

Air has also been used to fill the bladder, and has its supporters still. Most cystoscopists, however, prefer to fill with a fluid medium.

Another requisite is that the light shall be sufficiently powerful to clearly illuminate the bladder wall. In my examinations I have been wont to follow the directions given by Nitze, who stated that the light must be such as to have a dazzling white brilliancy outside of the bladder, and to be of sufficient strength to penetrate the filling fluid, and clearly and distinctly illuminate the bladder wall. As a result I have been forced to have stronger lamps than are usually furnished us in this country constructed for me, my lamps requiring 8 volts and  $\frac{1}{2}$  ampère. These are not of the so called "cold" type, and must be used with caution, so as not to burn the bladder wall; but the degree of illumination possible by means of them, and the clearness of the picture obtained with them, are such as to amply repay the additional care required in their use.

When a cystoscopy is to be performed my method of procedure is as follows: The patient is instructed to divest himself or herself of sufficient clothing to make it possible easily to reach and cleanse the genital organs. The patient is then placed upon the examining table in such a position as to give him or her the greatest possible comfort. I have found that a fully supine position is not desirable, since the

abdominal muscles are not sufficiently relaxed. The back rest is, therefore, raised at a slight angle, and the head and back made comfortable with pillows. The buttocks are approached as near as possible to the edge of the table, and the knees and thighs supported by the knee rests which I have devised. The thighs are then well separated and the external genitals thoroughly cleansed. The urethral canal is then irrigated with a solution of 1 in 20,000 bichloride (about 150 c.c. in amount) and a sterilized catheter inserted. Where necessary, in the male, the posterior urethra is anesthetized by the injection into it of a few c.c. of 1 per cent. solution of cocaine. In drawing off the urine in the male, I prefer to employ, where possible, a metallic catheter of about 22 French, since, if this passes easily, there is no longer any doubt concerning the passage of the cystoscope, which has a calibre of 21 French. The character of the urine is determined, as also its turbidity, or clearness. Should the urine be clear I at once proceed to the filling of the bladder. Should it be cloudy then the bladder is washed out until the fluid returns clear. A similar procedure is employed in the female, except that the ordinary female catheter suffices. The bladder having been distended, the cystoscope is now gently inserted. After assuring myself that the beak is really within the bladder cavity, which fact may be determined by rotating the instrument gently upon its axis, so that the beak is rotated within the bladder cavity, I proceed, in the female, to get an idea with regard to the size of the bladder, by employing the unlighted cystoscope to get the measurements of the bladder cavity. The beak of the cystoscope is pushed forward in the middle line until it is arrested, and the distance between this point and the vesical orifice noted. Thereupon I proceed to inform myself concerning the measurements, in a lateral diagonal direction, and, having determined these measurements, proceed with the examination. In the male, however, owing to the greater length of the urethra, these manipulations are impossible.

A regular routine is of value in the examination of the bladder. The margin of the sphincter and its surroundings should first be examined. The upper vesical wall comes next. The lateral walls follow upon this, and then the inspection of the posterior wall, and the trigone, as well as the posterolateral portions. Last comes the inspection of the ureteral orifices, and I usually end the examination by watching these orifices to determine the character of the urine which is discharged therefrom. We may, however, particularly where we suspect the ureters or kidneys, reverse this routine.

By means of the cystoscope we are able to determine whether the sphincter margins are normal or diseased—that is, whether inflammatory changes, papillomatous formations, or defects, etc., are present; whether the bladder wall is the seat, at any point, of inflammatory conditions, varying in degree from simple hyperemia to ulcerative or hemorrhagic changes; whether there are nodules, vesicles, new growths, diverticula; whether the bladder cavity is encroached upon by tumors from without; whether it is the seat of hypertrophied muscles, or whether it shows the scirrhus incrustations of proctitis, or the vesicles of ordema bullum, which

denote that a perivesical process impedes the circulation in the vesical wall; whether foreign bodies or calculi are present; whether there is prostatic hypertrophy or cystocele; whether the trigone is normal or the seat of inflammations or new growths; whether the ureteral orifices are both present; whether they are normal in location, in shape, in condition; whether they are singly or both discharging urine, or blood, or pus; if foreign bodies are present or tumors exist, the character and nature of the foreign body, the size and shape, and the probable character of new growths, and of ulcerations.

The injection of indigo carmine into the buttocks and the internal administration of methylen blue have been employed to serve as aids in locating the ureteral orifices in cases where their location is not otherwise easy. By their use the injection of a stream of colored fluid from the ureteral orifice serves to determine the presence, or absence, of a ureter, or functioning kidney. Of the two methods the former is preferable, since its result shows after a much shorter period of time than is the case when methylen blue is employed.

Recently there have been devised a cystoscope for the demonstration of the image to two observers at the same time, for use in teaching cystoscopy, one for stereoscopic presentation of the image, and one for retrograde examination, by means of which those parts just behind the vesical orifice, or behind an enlarged prostate, may be examined more easily and perfectly than is possible with the ordinary examining instrument.

None of these, however, has a broad field of usefulness. The prismatic type of cystoscope, as originally presented by Nitze, in 1879, is and will remain the instrument par excellence for the satisfactory examination of the bladder.

53 EAST FIFTY-EIGHTH STREET.

#### SOME REMARKS ON OCCIPITOPOSTERIOR POSITIONS.\*

By L. M. MICHAELIS, M. D.,  
New York.

Recognizing the obstetric importance of posterior positions of the occiput, and also the fact that the older textbooks were much too conservative in their estimates of the frequency of the occurrence of this position, the profession has of late years been paying more and more attention to the subject, as evidenced by the number of papers written on it, as well as by the interest shown in their discussion. Because the remarks I am about to make are the result of personal experience, I venture to add another paper, even though it be sketchy in character, to this growing list; for, to my mind, the fact cannot be too often reiterated that much maternal suffering, and, at times, danger, and also much fetal mortality can be avoided by the early recognition and prompt treatment of this obstetric annoyance.

Very many women have the occiput lying posteriorly at the very commencement of labor, but the position is rectified almost immediately, and hence these cases do not enter into consideration here.

\*Read before the Harlem Medical Association, February 1, 1908.

What the proportion of such cases is I will not venture to estimate. Let it suffice to state that the number is unquestionably very large. As for those in which the diagnosis is made, I find that in my own practice the number amounts to 30 per cent. in the last 100 cases which I have had, and I do not think that my experience differs materially from that of others interested in obstetric work.

We were taught that the reasons for the occiput being situated posteriorly were disproportion between passenger and passageway, excess of liquor amnii, and abnormal mobility of the child. In addition, I find that either combined with, or caused by these factors, or very often entirely independent of them and in their absence, incomplete flexion of the head is the underlying causative element. This latter, rather than the others mentioned, has been the cause in the large majority of my own cases, and its action in producing the posterior position is readily understood when one reflects on the improper adjustment of head to pelvis caused thereby, with the resulting tendency of the occiput to impinge on the posterior pelvic plane, and to be thus rotated toward the back, where it can more readily accommodate itself.

In many cases the diagnosis is easily made by examination, for the anterior fontanelle is found in front, while on palpation of the abdomen the depression between chin and chest of the child and the presence of small parts instead of the foetal back are plainly to be established. The position of the point of maximum intensity of the foetal heart sounds further confirms the diagnosis, for it lies quite off in the flank, well toward the mother's back. Yet where we find a case in which none of these points can be made out, where owing either to slight moulding or to a naturally small anterior fontanelle it is indistinguishable from the posterior, and where, in addition, the foetal heart is heard in the usual position for anterior occiput cases, and where neither depression nor small parts can be felt through the abdomen, we are apt, on having the child born looking up into our astonished faces, to feel deeply the uncertainty of things mundane. How, then, are we to arrive at a correct diagnosis? Here the general behavior of the case is of great assistance to us. In vertex presentations the early rupture of the membranes speaks for a posterior occiput in an overwhelming majority of cases. When this happens in anterior positions it is due either to excess of liquor amnii or to specially strong uterine contractions, thus putting an undue strain on the membranes, or to the fact that the membranes themselves are inherently weak. In posterior positions the undue strain is caused by the maladjustment between head and pelvis, for thereby neither the uterine contractions nor the resulting intrauterine pressure are equally distributed, while at the same time the bag of waters has not the regular globular shape which it should have normally. Thus, I always regard with suspicion a case in which rupture of the membranes precedes or is synchronous with the onset of labor. Owing also to the unfavorable mechanical conditions under which the uterus must act, due not only to this same maladjustment, but to the absence of the watery wedge as well, dilatation of the os is mark-

edly retarded, the first stage being, as a rule, unduly prolonged. This means that the woman suffers more than ordinarily from the trying pains of the first stage, with the not uncommon result of more or less complete maternal exhaustion before the os is fully dilated. Some observers mention a decided increase of the pain in the back in these cases. Personally I have never been able to confirm this symptom. Therefore, in the absence of any other complication, the man who makes the diagnosis of posterior position of the occiput from these two symptoms, early rupture of the membranes and slow dilatation, will seldom go far astray. Of course, if on vaginal examination an ear can be felt and its position positively learned, the diagnosis is easily and surely established.

If after full dilatation of the os the position of the vertex is not rectified, the tardy progress of labor continues on into the second stage, for the relation between the head in the posterior occipital position and the pelvis, and, frequently, an incompletely flexed head as well, is a decidedly unfavorable one mechanically. Naturally this is extremely apt to lead to further exhaustion on the part of the mother, and also to danger to the life of the child, because of the prolonged pressure on the head. In all cases, since the head is forced down on the cervix early in labor without the protective interposition of the liquor amnii, danger to that part of the uterus from grinding is greatly increased, while in those in which the posterior position persists throughout labor, perineal laceration is the almost invariable sequel. That there is grave danger of rupture of the uterus after long continued expulsive efforts in cases of impacted posterior occiput goes without saying, but as my object is to speak of the ordinary uncomplicated cases of this condition, I will not enter further into the discussion of these complicated ones here.

In regard to treatment, our efforts are at first directed to rectifying the malposition, converting it, if possible, by both postural and manual methods into an occipitoanterior position. This happy outcome is frequently obtained by having the patient lie on that side of the body toward which the occiput is directed. As she does this the fundus falls forward, to the side, and slightly upward, and the child's body consequently tends to be flexed on the head, and at the same time its back is thrown anteriorly, carrying the occiput with it, while the head, raised slightly out of the pelvis, can, and frequently does, impinge on the anterior plane during subsequent uterine contractions, and rotation is thus promptly and satisfactorily effected. As a substitute for this position the patient may kneel on the floor with a pillow under her knees, which is placed a little distance from the bed on which she rests her head and arms, while at the same time she advances the side toward which the occiput points somewhat more than the opposite one. This position acts exactly as does the lateral one, except that as the angle at which she leans away from the perpendicular is increased, the fundus is thrown further forward, augmenting the tendency to anterior rotation. The drawback to this kneeling posture is its discomfort; yet even though it is very uncomfortable for the woman in pain to kneel

at her bedside, it is decidedly preferable to the condition which it tends to obviate. For the matter of that, the lateral posture is frequently a source of discomfort to the patients, and I therefore let them alternate one with the other. The success of this treatment is marked, and the desired result is attained in a large number of cases. Unfortunately, this is not true in all, and in those in which it has failed I then proceed to attempt manual rectification, provided the os is sufficiently dilated to permit the necessary manipulation—in other words, that it is at least the size of a quarter of a dollar. The first step is the attempt to flex the head and then to keep it flexed during several successive pains. This in itself is often sufficient to cause anterior rotation, as mentioned before. If it is not, the next step is the effort to rotate the head manually. Two fingers are introduced, and, after the head is flexed, pressure in an anterior direction is made by them on the occiput with the object of bringing it to the front of the pelvis, while at the same time the other hand is used to assist rotation through the abdominal wall by pressing the trunk of the child upward and forward. This is most often successful when the head is just at or above the brim; when it is firmly wedged in the pelvis it is hardly necessary to say that this procedure is futile, except in very exceptional instances, until the ischial spines are passed. At this point in the pelvis, however, rotation is more readily effected with the forceps than with the hand.

In the presence of maternal or fetal exhaustion it is necessary to anesthetize the patient carefully, complete the dilatation manually if indicated, and then, after thorough flexion of the head has been obtained, apply the forceps. It frequently happens that in the presence of good flexion, the head plus the forceps will rotate anteriorly very soon after traction is commenced, provided the application is made with the head just engaged in the brim. This, of course, necessitates the removal and readjustment of the instruments. If anterior rotation does not occur then, it will, in most cases, when the ischial spines are passed and the head impinges on the pelvic floor. Rotary axis traction as described by Marx, in which the deliberate attempt is made to rotate the head with the forceps while making traction, is an operation which gives brilliant results, but it calls not only for operative skill on the part of the accoucher, but for absolute certainty in regard to the diagnosis and accurate knowledge of the mechanism involved as well. In the absence of these prerequisites it should not be undertaken, for it is then fraught with danger to the mother and vastly greater danger to the child.

As for podalic version in preference to the use of the forceps I have but a few words to say. Naturally, the indications for this operation, other than the position of the head, obtain here as elsewhere, but when it is thought of as a remedial measure for the malposition alone, I feel that the indications for its employment are extremely limited. When the head is absolutely free above the brim and operative interference is called for, a condition very rare indeed, then and then only, to be used, is very well indicated. Such an entirely uncomplicated condition, by which I mean uncomplicated by any

of the ordinary accidents of labor, would be the very exceptional one of early maternal exhaustion, or the equally exceptional one of essential uterine atony. In the vast majority of cases the liquor amnii has drained away, the uterus is more or less firmly contracted on the body of the child, and the performance of version, or rather, forced version, in such cases endangers both mother and child. Therefore, except in these few, rare cases, whenever operative delivery is called for, the forceps is indicated.

In all cases, but especially in those in which instrumental delivery has been performed, means for the resuscitation of the child should always be at hand, for the probability of its being born in a state of suspended animation is a complication with which, almost invariably, we are called upon to contend.

1090 LEXINGTON AVENUE.

## THE BLOOD CONSERVATISM OF NEUROTIC INDIVIDUALS.

BY JENNIE G. DRENNAN, M. D., C. M.,  
St. Thomas, Ont., Can.,

Medical Superintendent of the Amasa Wood Hospital.

We frequently notice the extreme pallor of certain persons, and noting it wonder how in the world they can exist and accomplish what they do, for frequently they are exceptionally active. The popular answer is: "O! they are living on their nerve." And we rest content with acknowledging that neurotics never die, while apparently healthy looking people easily succumb to disease and injury. "Never despair of a neurotic" ought to be as familiar a phrase as "never despair of a sick child."

It has been scientifically demonstrated that the blood of these same neurotics is not the blood of an anæmic person, howsoever much in other respects they may resemble one another; but the pallor of the one is not the pallor of the other; that of the neurotic is due to the absence of blood in the capillaries of the skin, and not as in the anæmic due to the presence in them of a blood poor in corpuscles. This blood circulates in the superficial capillaries of his skin and gives him the typical pasty, sometimes rosy, puffy appearances of the anæmic; while, on the other hand, the neurotic has empty capillaries in his skin. It has been scientifically demonstrated that if his skin is pricked with a needle no blood issues from the puncture, showing that there is an absence of blood in the capillaries of the skin, while in the case of the anæmic a thin, watery, reddish fluid issues, denoting the presence of a poor quality of blood. The neurotic is a shrewd individual; whether consciously or unconsciously so one cannot perhaps say, though my experience of him is that in many respects he is consciously so; though probably in this one respect I must admit that it is unconsciously that he regulates his blood supply for his own best interests. Nature wisely attempts to make a good use of the small amount of blood which such a person manufactures, normal in quality, but sub-normal in quantity, and therefore not sufficient for all the requirements of the body. To this come

mize she restricts the flow to the skin, allowing merely sufficient to maintain the skin in a condition of living, not of health, however, for the skin is tough and leathery, due to poor vascular supply; but it furnishes a covering for the body, even if its other functions are not performed. The bulk of the small blood supply of the body in these cases is sent to the most vital structures, and they are maintained in a fair degree of health, and to all appearances the person performs the ordinary and sometimes extraordinary duties of life as well as his more robust looking brother. Very often considerable of this scant supply goes to the brain and spinal cord, and a well nourished nervous system, even if it be in a neurotic person, regulates the other systems. His efforts may be spasmodic, but generally they are fit for the occasion. Never despair of one of these pallid workers flunking his duty, when necessity or ambition make demands upon him. The proverbial pallor of the hard student is accounted for in this same way; the bulk of his blood supply going to nourish his brain.

There is, on the other hand, the rosy neurotic, less often seen, who is also anæmic, and to whose skin considerable blood is supplied; there is not in this case the conservatism of the other, nor is the blood of such good quality. The skin in the pallid case is rather a foreign covering and not the true covering of a human body.

## Our Readers' Discussions.

### A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows:

LXXII.—How do you treat fracture of the patella? (Closed March 16, 1908.)

LXXIII.—How do you treat seasickness? (Answers due not later than April 15, 1908.)

LXXIV.—How do you treat sunstroke? (Answers due not later than May 15, 1908.)

Whoever answers one of these questions in the manner most satisfactory to the editors and their advisors will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred words.

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. All papers contributed become the property of the JOURNAL.

The prize of \$25 for the best essay submitted in answer to question LXXI has been awarded to Dr. Frank B. Kirby, of Philadelphia, whose article appears below.

### PRIZE QUESTION NO. LXXI.

#### HOW DO YOU TREAT GALLSTONE COLIC?

By FRANK B. KIRBY, M. D.,  
Philadelphia.

A case of gallstone colic demands immediate anodyne treatment. I give at once chloroform inhalations or a hypodermic injection of morphine sulphate  $\frac{1}{4}$  grain and atropine sulphate 1/100 grain, repeated in half an hour if necessary; externally the hot turpentine stupe or mustard plaster over the gallbladder. However, if the case is mild

in character, with slight pain, it will be relieved by

B Strychnine sulphate, ..... 1/60 grain;  
Ilyosecamine sulphate, ..... 1/250 grain;  
Nitroglycerin, ..... 1/200 grain.

with hot water, repeated every ten minutes to effect, usually three or four doses.

After pain the next most urgent symptom may be vomiting, although this may be slight or absent. If slight, it tends to overcome the spasm of the muscular structure of the duct, and if severe the drugs already used will tend to correct this trouble.

A third concomitant symptom is jaundice; this also may be absent. Jaundice is corrected by the use of the hot pack and fractional doses of calomel, say 1/6 grain for eight to ten doses to aid the emunctories, skin, kidneys, and intestines, without the usual subsequent saline, as the liver needs what bile is in the intestines to be absorbed for future use. The saline would cause a diarrhoea, and deprive the body of the valuable bile salts.

We determine the gravity of the situation after relief of its most urgent symptoms. Should we get a hectic temperature with leucocytosis and physical signs of distended gallbladder, all pointing to pus formation, we urge early cholecystotomy and removal of the stone. Should we decide on its benign character we give palliative treatment. This in effect is prophylactic as well.

Realizing its pathology we recognize no danger from the concretion *per se*, any more than a bullet encapsulated in the tissues. But as a possible cause of future trouble we determine on (1) the solution of the stone, and equally as important, (2) comparative intestinal asepsis. These we accomplish by the use of sodium glycocholate mass in three grain doses four times daily, with five grain doses of sodium succinate during several months. The former is one of the few true chologogue drugs, the latter has distinct value as an antiseptic and solvent for the concretion. Sodium succinate may be replaced by salol or sodium salicylate in the same dose.

The foregoing deals directly with the stone already formed. But true prophylactic treatment will not only prevent the hepatic colic of existing stones, but prevent the formation of other stones. Gallstones are chemically, cholesterin and calcium bilirubinate, which are only precipitated from bile, to form stones, by being in excess over their natural solvents, the glycocholate and taurocholate of sodium. This change is probably due to hepatic torpor and intestinal toxæmia, due to constipation and the sedentary habit.

I have never seen good results from the use of olive oil, and, in fact, restrict fats in the diet, also meat, substituting fruits and vegetables. It is also best to omit tea and coffee, and advise the free use of water. Walking in the open air is of value.

Exercise, correct diet, intestinal antiseptics with chologogue drugs form the keynote in the prophylaxis of gallstone colic.

5525 WOODLAND AVENUE.

Dr. Nathan Rosewater, of Cleveland, Ohio, says:

Diagnosis of gallstone colic being established, immediate treatment of the colic with a hypodermic injection of 1/6 to 1/4 grain of morphine sulphate, preferably combined with 1/150 to 1/100 grain of atropine sulphate, will usually relieve the

pain, control spasm, and correct the nausea and vomiting if reflexly present. Chloroform or ether may be used internally in small doses (5 to 10 drops), or by inhalation, if immediate relief is desired before the hypodermatic injection can be effective, or, in very mild attacks, these may answer alone.

When the pulse is intermittent and rapid, or the tension high, amyl nitrite by inhalation or nitroglycerin hypodermatically will aid in relieving spasm of the ducts as well as improve the circulation, provided the heart is strong. If not, 1/30 grain strychnine sulphate can be given. Hot applications or fomentations over the hepatic area are preferable to cold for quick relief. In extreme cases, with symptoms of shock, weak pulse, and cold extremities, hot applications to the extremities and entire body should be kept up. The colic may subside after the first dose of morphine and not recur, or more doses may be needed every few hours or hourly to relieve pain and induce sleep if needed. Be watchful lest you are not one of several physicians called in quick succession, each in turn administering a hypodermatic injection of morphine, unaware of previous dosages, with final fatal result, as is said to have occurred in the case of an ignorant patient thus treated for some painful malady.

Recurrence of attacks.—Gallstone colic can recur so long as irritating stones are present to provoke them, to prevent which, as well as to relieve the immediate attack if severe and threatening life, the immediate or remote removal of the gallstones must be seriously considered by all concerned, best of all, including a clinician and a surgeon, thus giving due weight to both surgical and nonsurgical advantages. In spite of urgent advice to submit to operation, the family or patient may refuse and prefer to temporize. This forces on us the question, have we a nonsurgical or medical treatment for gallstone colic recurrence, aside from the immediate relief? My answer is, yes. The history of large numbers of cases of permanent recoveries after medical treatment, by cautious observers, is not to be ignored. Surgical treatment, though far oftener positively preventive, is not in every case so, so that while medical treatment has its limitations and may result in a history of prevention which is debatable, let us not forget that absolute proof of prevention of anything is impossible, so, too, even after no recurrence of gallstone colic for years following any treatment, not even the post mortem examination can prove an actual prevention of gallstone colic. No removal of the stone, without the knife, can be expected where stones are too large to pass the ducts or where contractions or adhesions or other mechanical obstructions exist, unless by some solvent action on the stones. These cases of almost inevitable failure of medical treatment may cast ridicule upon such treatment in general, but should not lessen our ardor and confidence in the ever widening field of medical therapeutics, and if these causes for failure are frankly stated in advance to the patient he will the more readily give his consent for final operation.

Medical treatment to prevent recurrence of gallstone colic must consider the coexisting factors in

its production, to determine what means are applicable in preventing recurrence.

The coexisting factors are: 1st, the gallstones, which of themselves can remain dormant through life and not give rise to colic; 2d, the conditions that are said to produce the stones, of which we know nothing positive; 3d, the vulnerability and sensitiveness of the area involved—here we may have constitutional and local conditions, luetic, lithæmic, toxic, local inflammation, etc.; 4th, a study of the conditions that provoke an attack, such as drag, motion causing friction, spasm, passage of stone, temperamental conditions, diet, habits, acute infection, etc. Thus, removal of gallstones, as also preventing gallstone formation, prevents attacks, so, too, rendering the involved area invulnerable or insensitive to pain would also do so, and, again, if the conditions can be sufficiently modified, as by dilating the ducts or softening or dissolving enough of the surface of the stones to make them smaller, or lubricating their path enough to make them slip onward, or by relieving a spasm which is holding them too tightly, each of these would thus act as an agent for inhibiting attacks.

Motion during an attack and even afterward should be limited, as it tends to increase local irritation and colic. During the attack this is best favored by the recumbent position, with legs flexed, or changed to any position affording relief; elevation of the foot of the bed will also be useful, especially to the obese, in overcoming traction upon the gallbladder and ducts, and still more so if adhesions aid in causing the colic or in cases of enteroptosis and hepatoptosis. By partially immobilizing the epigastrium, and especially the gallbladder region, lifting up and supporting the belly by means of 3 inch wide strips of zinc oxide adhesive plaster, which method I have fully described in Dr. Rose's *Atonia Gastrica* (pp. 96-120), I prevent traction upon the irritated bladder and ducts, and my patients sometimes secure great relief, one patient thereafter doing her housework and a large washing for a number of months, although tenderness and pain on pressure repeatedly showed that the gallstone condition, though present, was absolutely relieved by the supporting bandages. Subsequent operation revealing a large number of small stones in the gallbladder. This supporting bandage gives relief not alone from traction upon adhesions, but it prevents elongation and consequent narrowing of the ducts and bloodvessels by gravitating drag, enables some stones that are too large to pass the narrowed ducts to escape more readily because such support restores the ducts to greater and more nearly normal calibre, and renders them less irritable and sensitive to the passage of stones. While the Gallant corset or the abdominal belts also give similar support, they are not so effective. Rest from irritation, friction, and spasm can be given by antispasmodics and lubricants. Possibly stones are held by spasm in the ducts, just as a string is held in the oesophagus or urethra. Relief of the spasm by morphine, atropine, ether, chloroform, etc., may be the means of allowing such stones to pass. So, too, local applications of heat, fomentations, etc., counter treatments such as mustard, relieve not only the colic, but also the irritability and local congestion. Lubricants, including oils such as olive oil,

oleate of soda (castile soap), have been reported by many careful observers as aids in expelling the stones, acting by mechanically overcoming spasm, as oils do in pylorospasm. Probably the oil reaches the ducts in a circuitous route through its property of rising above its normal level in its containers or through antiperistalsis.

The origin of gallstones from infection is urged by some, and suggests studying in each case the nature of any possible infection that could render this area vulnerable, and any traceable, constitutional, or infectious cause should be treated, be it of a malarial, colon, typhoid, luetic, rheumatic, or tuberculous origin. The benefit derived from salicylic acid and its alkaline salts in so large a number of cases, and its usefulness in various infections accompanying rheumatism, whether as cause or complication, may be accredited to its antimicrobial action locally and constitutionally. So commonly have I observed rheumatic symptoms accompany as well as precede gallstone attacks that I have found in just such cases, both during and following the attack, very great satisfaction in the use of sodium salicylate in doses of 10 to 15 grains dissolved in a half glass of water every three hours for the first day of the attack, and later one or two hours before meals and at bedtime. I cannot recall a case in which it disagreed with the patient. At the hours named there should be no undigested food in the stomach, so that it can scarcely inhibit gastric digestion, while it inhibits fermentation and putrefaction, until later on it is absorbed by the villi into the blood. Its prolonged use I have never seen followed by albuminuria or by any toxic effect, nor have I, as a very heavy prescriber of it, used any of the so called salicylates made from oil of wintergreen. Its action as a solvent of uratic deposits may also explain its virtues in these cases.

Serum therapy may be useful when perfected, and we are able to more accurately diagnosticate those cases due to a specific infection.

The value of mercury in many infections is well established, and many have recommended it in the preventive treatment of gallstone recurrence, its effect as observed being due to its local antiseptic as well as to its constitutional effect, and no doubt in luetic and other infections it may be preferable. These and other drugs, by inhibiting or destroying infection of the irritated area, and by thus limiting inflammatory processes if present, have a special place in rational treatment.

Cholagogues.—Whatever tends to increase the fluidity and volume of bile may aid in flushing out small concretions; for this purpose plenty of water, sojourn at watering places such as Vichy, Carlsbad, etc., are reputed of special benefit. Constipation being an acknowledged aetiological factor, the drinking of quantities of laxative and cathartic waters, the long stay and constant use of these at watering places, keep the intestinal canal flushed and prevent stasis in the portal circulation, thus favoring a normal hepatic circulation and a free flow of bile, factors tending slowly toward restoration to the normal of the involved area. The cholagogue action of sodium sulphate, sodium phosphate, and alkaline salts generally may explain their reputed efficiency in such cases. To this list of cholagogues may be

added sodium cholate and fatty oils such as olive oil; the latter—acting also as a lubricant, perhaps too as a solvent—is worthy of trial in doses of one ounce before meals and at bedtime.

Diet also plays a part, and in certain cases, especially the lithæmic and autotoxic, on whom it is a most important element in treatment, also in the strictly gastric cases with digestive disorders, and in nephritics.

During paroxysms of colic withhold all food and give what is safest, water, preferably hot, and as much as can be tolerated, returning to usual diet by slow degrees. Gastric cases must be treated along individual lines.

In cases with a rheumatic, lithæmic, or nephritic history I give a diet, allowing only meats freed from their extractives (purin freed) by removing the first two, soups, and then preparing the meat for the table suitable to the culinary art. I allow no meat soups, nor tea, coffee, cacao, or chocolate, while sugar, starch foods, and fruits are restricted. Alcohol must be curtailed or prohibited, since its toxic action on the liver taxes this already overstrained organ. Well cooked vegetables are allowed, and those foods not specially interdicted. Avoidance of worry, cheerfulness of mind, pleasant surroundings, diversions of travel, etc., aid, especially when, as an aetiological factor, the mental and nervous influences act as deranging or exciting causes.

*Dr. W. Emory Hyskell, of Meadville, Pa., remarks:*

In view of the fact that gallstone colic is caused by the acute impaction of one or more gallstones in one of the large bileducts and is associated with intense pain, faintness, and more or less nausea and vomiting, the first thing to do in all severe cases is to give the patient a hypodermic injection of  $\frac{1}{4}$  to  $\frac{1}{2}$  grain morphine sulphate, combined with  $\frac{1}{100}$  grain atropine. This anodyne will have to be repeated often enough to give the patient a comparative degree of comfort. If the colic is very severe, it is well to give a few whiffs of chloroform to ease the pain till the morphine has time to act.

The morphine decreases the agonizing pain, and in conjunction with the atropine relaxes the spasm of the muscular layers of the biliary ducts. Frequently this relaxation allows the impacted stone to pass without further trouble.

Six or eight ounces of olive oil or one ounce of glycerin should be given during the attack of pain, as this aids in relaxing the spasm of the bileducts and has a good aperient action on the bowels. Hot fomentations or hot turpentine stupes should be placed over the liver, as they are soothing to the patient and also have a relaxing effect.

In severe cases give a laxative enema; in mild and in subacute cases give calomel in small frequently repeated doses until there is a free movement of the bowels; then watch the feces to see if any gallstones pass.

Keep the patient at rest in bed, and if the colic is very severe do not give any food or any water by the mouth, except in small amounts to relieve thirst, as it would excite peristalsis and increase any existing inflammation or local peritonitis that might be present. Give nutrient enemata instead.

As soon as the pain is lessened enough to permit you to do so, take a full history of the case, noting especially if the patient has ever had any similar attacks, and make a thorough examination of all the thoracic and abdominal viscera, thus making sure of your diagnosis and ascertaining if there is any other diseased conditions present with which you have to deal. Also get a specimen of urine and examine it for bile and for any existing disease of the kidneys.

If the severe pain lasts more than a few hours, if there is much enlargement or tenderness of the gallbladder, or if there is high or irregular temperature, call in a surgeon in consultation, with view to operating if it becomes necessary.

In order to carry out the farther treatment of gallstone colic intelligently, it will be necessary to study the causes of gallstone formation and adapt your treatment according to the indications of each individual case. The following are the most usual predisposing causes:

1. Cholangitis and cholecystitis.—The inflammation produces an excess of mucin and diminishes the alkalinity of the bile. This allows the calcium salts and the cholesterol to combine with the mucin and form a nidus for gallstones.

2. Gouty and allied diatheses.

3. Infection.—Bacteria gain entrance into the bileducts and gallbladder by way of the common duct, the bloodvessels, or the lymph channels, keep up the inflammation, and sometimes form nuclei for gallstones.

4. Stagnation of bile.

5. Digestive disturbances.—These produce inflammation, which often extends to the bileducts and gallbladder.

6. Circulatory disturbances.—Congestion of the liver interferes with biliary secretion and causes stagnation of bile.

The following treatment is adapted to patients after the severe pain of the first stage of gallstone colic is passed and to subacute and chronic cases. As no drugs can be given that will dissolve gallstones, the aim in our treatment should be to repair the damage already done and relieve all conditions that have a tendency to aid in the formation of others.

To those cases with inflammation of the biliary passages give sodium salicylate or sodium succinate to grains three times a day. This relieves inflammation, increases alkalinity, and checks infection. Phenolphthalein, 3 to 5 grains, can be combined to advantage with the salicylates. Oil of turpentine, 5 to 10 minims, in capsules, three or four times a day, gives brilliant results with some patients. Phenyl salicylate is a useful intestinal antiseptic. Ammonium chloride acts well in cholangitis.

Pure nitrohydrochloric acid, 3 to 5 minims, well diluted in water after meals, aids digestion and stimulates hepatic secretion.

Hepatic congestion should be relieved by the remedies that are indicated by the conditions producing the same. Heart tonics and stimulants may be indicated. If there is a tendency toward visceropneumonia, a well adjusted abdominal binder often gives relief.

A dose of effervescent sodium phosphate in a

glass of cool water, taken slowly each morning before breakfast, is a valuable adjunct to our other treatment. The phosphate stimulates the hepatic cells, acts as a laxative, and aids in the elimination of the byproducts of metabolism.

The Spa treatment often gives good results, and should be recommended in suitable cases. The alkaline laxative waters are very useful if taken properly and faithfully kept up.

All gastrointestinal troubles should be corrected. The food should be limited in amount, eaten slowly, and thoroughly masticated. It should contain plenty of green vegetables and fresh fruit, while the carbohydrates, hydrocarbons, fried foods, sweet cakes, all rich foods, and alcoholic beverages should be avoided.

Every patient, when at all able, should have plenty of well regulated exercise in the open air and sunshine. Exposure to wet should be interdicted. Horseback riding is the best exercise for patients with hepatic torpor, as it jolts the liver and causes the stagnant bile to flow on more freely, gives exercise to nearly all of the muscles of the body, affords pleasant diversion for the mind, and keeps the patient out in the open air and sunshine.

*Dr. Frederick Fletcher, of Columbus, Ohio, writes:*

The victim of an agonizing paroxysm of gallstone colic demands quick relief. And the physician invariably meets the emergency by instituting a time honored treatment. The suffering incident to an attack of colic may last from a few seconds to a week or longer. It is for this reason that the persistent treatment and variety of applied therapeutic measures are in keeping with the remissions and exacerbation of the symptoms.

Theoretically, the subcutaneous use of morphine and atropine, or the inhalations of chloroform, are indicated for the relief of the pain and spasm. And when this treatment is supplemented with rest in bed; a hot bath, the local use of dry heat, or poultices over the hepatic area; the giving of an enema, or the ingestion of olive oil or a large quantity of hot water, we not infrequently relax the muscular spasm, and, with the dislodgment of the stone, cure the patient. But this treatment is purely symptomatic, and takes cognizance of nothing other than the stone as the exciting factor. Again, the large amount of morphine necessary to produce quietude has the effect of obstinately constipating a patient whose bowels should move regularly, so that it becomes necessary for the physician to actively disturb the entire gastrointestinal tract in an attempt to empty the stagnant bowel.

It is of practical importance to know that digestive disturbances are symptomatic of cholelithiasis, and that any indiscretion of diet is prone to excite an attack of gallstone colic. It has been pointed out that the spasmodic contractions of the gallbladder occur synchronously with the contractions of the stomach. This physiological facts suggests a rational method of treatment, namely, the removal of the irritating gastric contents by lavage.

#### *Treatment.*

During the passage of a gallstone the chief measures to be carried out are: (a) Rest in bed. (b) The stomach should be rested, and not insulted by

the administration of nourishment or liquids. Thirst can be controlled by the rectal use of normal salt solution. (c) The stomach should be irrigated with a large quantity of hot water, preferably a solution of sodium bicarbonate, one drachm to the pint of water. If the pain and vomiting persist, the irrigation should be repeated at the end of an hour, or at any time the taking of nourishment excites a paroxysm of colic. Vomiting is not a factor when the stomach is relieved of its irritating contents.

This form of treatment will cure the average attack of gallstone colic without recourse to opium. However, it may be necessary, in the exceptional case, to give a single dose of morphine and hyoscine, or to keep the patient submerged in a tub of hot water. Lavage can be practised with the patient in a tub. Collapse is met with the use of stimulants.

Good results follow the intelligent administration of olive oil. It is the lavage effect of the quantity of oil used in the stomach, rather than a direct therapeutic action of the drug upon the hepatic apparatus, that effects the cure. The oil should be administered *through a stomach tube*—it should be warm, and given in a quantity of not less than one and a half pints.

For the prevention of gallstone colic attention to diet and hygiene is most essential. Cholecystotomy is the rational prophylaxis.

Operative treatment is not advisable during the attack of colic. However, if there are indications of a permanent lodgment of the stone in either the cystic or common ducts, or symptoms suggestive of a perforation or suppurative process, prompt surgical interference should be advised.

*Dr. Howard Priest, of Fort Bayard, New Mexico, observes:*

The treatment of gallstone colic resolves itself into three factors, namely, prophylaxis, medicinal relief, and surgical intervention.

These three methods will be considered in their respective order.

Firstly: Prophylaxis. This is the treatment between attacks, for an attack must occur to demonstrate the existence of biliary calculi. Possibly the Carlsbad treatment ranks foremost; certainly the springs take precedence over the bottled waters or the natural or artificial salts. A teaspoonful of sodium phosphate dissolved in a tumblerful of hot water and taken three times daily, a diet directed to be taken regularly thrice daily, the heaviest meal at midday, and the meals consisting of easily digestible nourishing food, excluding fats, excess of carbohydrates and alcohol, combined with judicious exercise, bathing, and thorough regulation of the bowels, continuing for a period of from four to six weeks, probably approaches as near to the ideal as does the Carlsbad method. Sweet oil as a solvent is mentioned, but not recommended.

Secondly: The medicinal treatment during the attack. There are two ends to be accomplished in this. The relief of the pain and the correction of the inflammation. The usual resort is to hypodermatic injections of morphine,  $\frac{1}{4}$  grain and atropine  $\frac{1}{100}$  grain, combined. The inflammation is best controlled by a few days' rest in bed, light diet, external applications of hot water, poultices, and

stupes, and the internal administration of belladonna, hyoscyamus, and cannabis indica. The pain may be so severe as to call for inhalations of chloroform or ether.

Thirdly: The surgical intervention. In view of the comparative low mortality attending such procedures this should appeal to physician and sufferer alike. Results are usually permanent, while the nonoperative measures, more than frequently, constitute a continuous performance. The nature of the operation, a cholecystotomy, a cholecystostomy, or a cholecystectomy, is determined by the pathological conditions present.

Certain contraindications to the operative treatment occur, such as diabetes, chronic pulmonary and cardiac diseases, arteriosclerosis, and excessive adiposity; but in the main the surgical treatment gives more satisfactory and lasting results.

*Dr. Walter E. Hays, of New York, states:*

The treatment of an attack of gallstone colic resolves itself into chiefly the alleviation of the special symptom of pain, since there is no means by which we can directly reach the seat of the trouble. The attack begins with agonizing pain in the region of the gallbladder and thence radiates to the right shoulder usually, though it may be felt in any part of the trunk or even radiate to the extremities. It often seems very pronounced in the epigastrium. The pain is produced by the passage of a biliary calculus through the cystic or common bile ducts, or both, into the duodenum. Consequently, our ultimate effort should be directed toward aiding in the expulsion of the stone into the bowel.

Nothing will suffice to relieve this intense agony but opium in full dosage. If there is no vomiting, powdered opium, grs. ii, combined with extract of belladonna, gr.  $\frac{1}{4}$ , should be given by mouth and repeated as often as necessary. Or, if nausea and emesis are present, morphine sulphate, gr.  $\frac{1}{4}$  hypodermatically, with atropine sulphate, gr.  $\frac{1}{150}$ , should be administered. The belladonna or its derivative will offset the nausea often produced by the opiate, especially the morphine, and also acts as an antispasmodic. Oftentimes a few whiffs of chloroform will deaden the pain in a very severe paroxysm until the opiate has had time to work. After the initial dose of the anodyne, the patient should be placed in a bath as hot as can be well borne by him for at least ten minutes. He should then be put to bed and hot fomentations applied to the entire upper abdomen. Allbut says that at times the drinking of a pint of water, as hot as can be taken, will aid in assuaging the pain. In the case of inflammatory processes going on in the gallbladder, however, the hot applications are not so well borne. In such cases leeches or cold compresses will often relieve when placed over the painful area. The former are serviceable in plethoric individuals and may alleviate the spasms. Antipyrine, acetphenetidin, and other coal tar derivatives have been recommended, but frequently their use has to be supplemented by the administration of opiates. Consequently, it is much more satisfactory to employ the opium first. All these measures not only allay the pain due to the passage of a biliary calculus in the cystic or common ducts, but also relax the spasm of their musculature

and thus permit the escape of the stone into the larger common duct or into the duodenum, as the case may be.

The nausea and vomiting of gastric contents, and later, frequently, of bile, usually leaves the patient in a temporarily exhausted condition and produces relaxation of the pylorus. This favors the onward movement of the stone. If, however, retching continues, the administration of olive oil will often quiet the spasm of the pylorus. Olive oil, ether and oil of turpentine have been much lauded because of their solvent effect on the gallstones, but, as they cannot in any way be brought into contact with the stones, their use is barren of results. Musser maintains that olive oil acts well in relieving the hyperacidity of the gastric juice, usually associated with gallstones, and causing simple gastralgia or pyloric spasm.

It is advisable, during the attack, to secure a good evacuation of the bowels, or as soon as possible after the attack begins. For this purpose, epsom or rochelle salts, magnesium citrate, castor oil, etc., in full dose, or a pill composed of podophyllin, gr.  $\frac{1}{4}$ , and extract of belladonna, gr.  $\frac{1}{4}$ , are useful, but they are frequently vomited. It is then necessary to employ enemata. Simple hot or cold soapsuds enemata may be tried, or injections of olive oil in case the stools are very hard. Or, if these avail not, a purgative enema consisting of magnesium sulphate, glycerin, olive oil, of each an ounce, oil of turpentine 2 drachms, water to make six ounces, may be tried, and will usually be found very efficacious, though it may have to be repeated in two or three hours.

It is doubtful whether a chill can occur or fever be present in an uncomplicated case of gallstone colic, though some authorities maintain that such cases have been observed. With the expulsion of the stone, however, this pyrexia disappears, though it may return with further pain.

Jaundice will be observed when the stone lodges in the common duct and completely blocks its lumen. This disappears with the dislodgment of the stone.

This medical treatment is chiefly palliative. After an attack, care should be taken to prevent a recurrence. The regulation of the diet is important. The amount of lime salts ingested should be kept down by the eating of small quantities of farinaceous foods. The nitrogenous food elements should be increased in amount, as cholesterin, the chief constituent of biliary stones, is precipitated when there is a deficiency of solvents in the bile, these solvents being the glycocholate and sodium taurocholate, derived from the metabolism of nitrogenous food (Allbutt). Exercise and proper attention to the bowels will also prevent stagnation of the bile in the gall-bladder. The dress should be regulated by women to avoid pressure on the liver and gallbladder. Musser likes the use of ammonium chloride, where there is congestion or a tendency to stasis of bile, as it has an influence upon the secretions and is said to thin the bile, allay catarrh, and modify the amount of mucous secretion. The use of sodium phosphate or other saline salts of value but whether they act on the liver itself or as purgatives is not known.

If consent of the patient can be obtained, relief from the gallstones should be permanently secured by surgical procedure. Thus these severe and periodic paroxysms of pain can be obviated.

## Therapeutical Notes.

**The Nonspecific Treatment of Diphtheria.**—In the absence of diphtheria antitoxine serum, Délarde, Minet, and Bricout, of Lille, recommend the following method of treatment (*Revue française de médecine et de chirurgie*, February 25, 1908; *L'Echo médical du nord*, October 6, 1907):

Thrice daily, morning, noon, and night, daub the throat with a mixture of the following composition:

R Menthol, ..... 5m;  
Camphor, ..... 5i.

M.

[Mixed in these proportions menthol and camphor form a liquid.—ABTRACTOR.]

If it is required the mouth may be washed out with a five per cent. solution of chlorinated soda, or a two per cent. solution of hydrogen dioxide water.

Thrice daily drop in each nostril a teaspoonful of the following:

R Menthol, ..... gr. ivss;  
Camphor, ..... gr. ii;  
Resorcin, ..... 5ss;  
Olive oil, sterilized and washed with alcohol, ..... 5iiss.

M.

The patient should be bathed in lukewarm water every morning:

If there is bronchitis mustard plasters should be applied twice a day.

When the laryngeal exudation loosens up its elimination is accelerated by an expectorant mixture of the following composition:

R Sodium benzoate, ..... gr. xxx;  
Oxymel of squill, ..... 5ss;  
Syrup of tolu, ..... 5v;  
Syrup of acacia, ..... q. s. ad 5iv.

M.

Dose: One teaspoonful to a tablespoonful, according to the age of the patient, every four hours, in a little warm milk.

**The Treatment of Warts.**—The following topical applications for warts are cited in *Bulletin général de thérapeutique* for February 23d:

I.

R Extract of cannabis indica, ..... gr. viiss;  
Salicylic acid, ..... gr. xv;  
Collodion, ..... 5v.

M. Sig. Paint the warts nightly with the mixture.

II.

(Bakke's compound.)

R Potassium bichromate, ..... gr. iss;  
Tincture of iodine, ..... 5ss.

M.

III.

(Mason's Paint.)

R Alcohol (proof), ..... 5i;  
Salicylic acid, ..... 5i;  
Acetic acid, ..... xv;  
Ether, ..... 5i;  
Collodion, ..... 5ss.

M.

**Nutmeg Poisoning.**—In an address to the Therapeutical and Pharmacological Section of the Royal Society of Medicine, at a meeting on January 28th (*The Prescriber*, March, 1908), Professor Cushny dealt with the subject of nutmeg poisoning. It had been found that cases of poisoning occurred exclusively from the use of crude nutmeg or some. Nutmeg does not appear to have any abortifacient

action, although it has been used for this purpose. The symptoms generally resemble those of cannabis indica, and include drowsiness, stupor, diplopia, and sometimes delirium and burning pain in the stomach. He considered that the symptoms were to be attributed to action on the central nervous system, which was depressed, but exhibited some indications of stimulation in the form of restlessness, slight convulsive movements, and tremor. The oil had a marked local irritant action, whether given by the mouth or hypodermatically. The stomach wall was found red and injected, and the urine often contained albumin. Dr. Power said he had found the chemistry of oil of nutmeg to be of a very complex nature. It was significant that the quantity of nutmeg required to produce symptoms of poisoning represented a very small amount of myristicin, and he had doubts as to whether this body was really responsible for these symptoms.

**Antimony as a Hepatic Stimulant.**—By its influence in promoting secretion from the intestinal mucous membrane, antimony, says Eustace Smith (*The British Medical Journal*, February 29, 1908), is a useful addition to the aperient in cases of chronic constipation where the stools are exceptionally dry and hard. It was to its quality as a hepatic stimulant that it owed its inclusion in the old pharmacopoeal preparation known as "Plummer's pill," in combination with calomel and guaiacum. Smith suggests the following combination in pill form for use in cases of chronic constipation:

R	Tartarated antimony, .....	gr. 1/25 to gr. 1/20;
	Podophyllin, .....	gr. 1/6;
	Compound extract of colocynth, .....	gr. 1/2;
	Extract of belladonna, .....	gr. 1/6;
	Extract of nuxvomica, .....	gr. 1/4.
M.	ft. pil. No. i.	
Sig.	One pill to be taken each evening before dinner.	

**Draught for Alcoholic Intoxication.**—Pouchet is credited in *La Quinzaine thérapeutique* with the following prescription for overcoming the symptoms of alcoholic intoxication:

R	Ammonium acetate, .....	3i;
	Sea salt, .....	gr. lxxv;
	Infusion of coffee, .....	3iiss;
	Simple syrup, .....	3i.
M.	Sig.: Give in two doses, fifteen minutes apart.	

**Aperient Salt.**—The composition of the aperient salt, commonly known as Harrogate salts, and which is a favorite purgative in gout, rheumatism, etc., is given in the *British Pharmaceutical Codex* as follows:

R	Potassium bitartrate, .....	3i;
	Sulphurated potash, .....	gr. xii;
	Magnesium sulphate, exsiccated, .....	3vss.
M.	Dose, 3i to 3ii.	

**Fluoroform for Whooping Cough.**—According to Tissier (*Journal de pharmacie et de chimie; Pharmaceutical Journal*, February 8, 1908), a saturated aqueous solution of fluoroform which contains 2.8 per cent. of fluoroform is odorless, colorless, almost tasteless, and less toxic than bromoform solution. It is a specific for the treatment of whooping cough. It has been given during the past four years in 117 cases without a single untoward symptom, even when large doses were administered. After the second or third day the number of paroxysms is less-

ened, and in a week they disappear. No bronchopulmonary complications occur; if these already exist they are speedily cured. Fluoroform should be given in sufficient doses, or it will not act. For infants up to two years of age one drop of the saturated solution may be given after each paroxysm, and two drops on the second day, three drops the third, and so on, progressively, not exceeding a total daily dose of 100 drops. From two to four years the doses may be increased to 75 to 150 grains (50 to 100 drops) in twenty-four hours. Above this age half an ounce of the solution may be given in subdivided doses in twenty-four hours, and adults may take twice as much. The fluoroform solution may be taken in milk, or water, or alone. Its administration causes no gastric disturbance. Larger doses than above indicated may be given, but they serve no useful purpose.

**Enema After Abdominal Section.**—After abdominal section cathartics cannot be given by the mouth on account of nausea. In such cases when it is desirable to secure bowel movement the following enema, high into the rectum, may be given (*American Journal of Clinical Medicine*, March, 1908):

R	Epsom salt, 50 per cent. sol., .....	3ii;
	Oil of turpentine, .....	3ii;
	Glycerin, .....	3ii;
	Water, .....	3vi.

M.

The injection is to be held in the bowel as long as possible by the patient. It is well to anoint the inner surface of the thighs and the buttocks in order to prevent irritation of the parts should they come in contact with the turpentine by any mischance.

**For Tænia Solium.**—The following formula is taken from *Bulletin général de thérapeutique* for February 29, 1908:

R	Oleo-resin of male fern, .....	3i;
	Rectified oil of turpentine, .....	gtt. xx;
	Chloroform, .....	gtt. xv;
	Mucilage of acacia, .....	5i.

M. Sig.: One half to be taken at night, and the other half the following morning.

**Suppository for Dysmenorrhœa.**—

R	Morphine hydrochloride, .....	gr. 1/4;
	Extract of hyoscyamus, .....	gr. 1/6;
	Cacao butter, .....	gr. xxx.
M.	ft. suppositorium No. i.	

**Inhalation for Catarrhal Pneumonia.**—Marfan (*Journal de médecine de Paris*, December 29, 1907) advises the inhalation three or four times a day from a teapot or steam kettle a teaspoonful of the following mixture added to eight ounces of water:

R	Creosote, .....	3i;
	Tincture of benzoin, .....	3iiss;
	Oil of turpentine, .....	3iii.

M.

**Glyceroboric Ointment.**—The following ointment is said by *Nouveaux remèdes* to be superior to boric ointment as an antiseptic. It has a consistency like cold cream, and is an agreeable substitute for iodoforn or carbolic ointment:

R	Boric acid, .....	3ii;
	Glycerin, .....	3iii;
	Wool fat, hydrous, .....	3iv;
	Petrolatum, .....	3ii.

NEW YORK, SATURDAY, MARCH 28, 1908.

## "A MIND THAT FOUND ITSELF."

No one can read the stirring introduction of an autobiography of Mr. C. W. Beers in a recent work, *A Mind that Found Itself* (Longmans, Green, & Co., New York), without being tempted to do something. "I am not telling the story of my life just to write a book," says Mr. Beers. "I tell it because it seems my plain duty to do so. For what purpose was my life spared? That question I have asked myself, and this book is, in part, an answer." This is the author's introduction to a human document which constitutes one of the most fascinating chapters in the psychology of insanity that have been written for many years.

Mr. Beers calculates that there is about one in every eighty of the population of the United States suffering from some form of mental disease—a high estimate, if the statistics of the Census Bureau are at all reliable; and the great pity is that so little, he says, "is being done to combat the present irresistible advance of insanity." While we feel that the author's outlook as to what is being done is lamentably narrow, and that he would not really have to "combat" the "irresistible," yet we are at one with him in the feeling that we are neglecting opportunities that he does so in vain to understand this marked increase in mental derangement. We welcome the harshest criticism from the outside, feeling that our own words fall on dead ears.

The author's early life, his graduation, his training, his early illness, his attachment to mental hospitals,

insanity, and his recovery, are all told in a simple yet striking manner that compels attention. Even the chapters dealing with the abuses to which he was subjected have more interest in them than the usual run of asylum abuse descriptions, because the author's insight into his condition was so well preserved, and his literary quality betrays a humor that is a saving grace.

We feel that this work should be read far and wide, for through it we hope may come the remedying of certain drawbacks that prevent the insane from receiving the care that should be their portion. We recommend this work, not that we feel at one with the author throughout, but because he has put his finger with precision upon those very things for which asylum superintendents have been working for years. The unheeding public look upon our large asylum structures and wonder why such palaces should be built. The unheeding used to wonder in the same way at Bedlam two hundred years ago; they feel that too much money is spent on the insane, and the legislators skimp and save and cut down—and where? In food and in attendants, the two most essential features in the care of the mentally disordered. The same legislators allow one physician to about two hundred patients; one nurse or attendant to fifty, to thirty, to twenty, under the best of circumstances; and (sometimes) such attendants! We can feel with Mr. Beers that they have been chosen for their physical prowess rather than for their intellectual capacity. How much are they paid? The answer to this question will go a long way in explaining the preponderance of brawn over brains.

We can sympathize with the author's dissatisfaction in not obtaining proper redress, but we feel that he is ill prepared to speak of the real reasons why control of the attendants is not the simple matter that he supposes. It is not over a year now since a well known medical director in one of our better institutions for the treatment of the insane actually had to compel a district attorney to prosecute an attendant who had assaulted a patient. This superintendent was not content to dismiss the attendant, he had him indicted and punished, and largely on the evidence of so called insane patients. We should like to see a recognition of this feature of the situation in Mr. Beers's book, but, apart from the fact that a more general reading of this work would tend to make it easier for other superintendents or medical directors to deal more effectually with brutal attendants and careless and incompetent medical assistants, we also feel that it may help to bring about a change in the treatment of "insane" patients. While we cannot imagine how progress in general in the better care of all classes of the insane

tally sick, the care and treatment of the acutely violent have seemed to have been benefited little since the days of Julius Cæsar, when the use of poppy and of henbane was advised for the violent, and it was said that only those who would hurt themselves or others should be kept in chains. Plenty of space, enough attendants, good food, frequent baths, and constant medical supervision; these are reforms for which psychiatrists have been striving for two hundred years, and toward the bringing about of which we believe that Mr. Beers's book, even with its obvious defects, may contribute.

### AN IMPROVED BIRTH RATE IN NEW YORK.

For many years the death rate of the city of New York, both the old city and the present enlarged territory included under the name, has been higher than it ought to be, and it has not been offset as it should have been by a high birth rate. There is some reason to hope, however, that the ratio is destined to become approximately normal. One swallow, indeed, does not make a summer, but the lone bird is promising, for all that. A straw betokening what may turn out to be a favorable wind is to be found in the birth rate reported to the State Department of Health for the month of January of the present year, as we find it set down in the February number of the board's *Monthly Bulletin*.

During the month of January 11,853 living children were born in the entire city. The population is estimated as 4,244,411. Therefore there was a calculated annual birth rate of 33.5 to each thousand of the population. In two of the five boroughs, indeed, the calculation gives figures somewhat larger still, the rate set down being 34.0 in the borough of Manhattan, and 33.9 in the borough of the Bronx. It is given as 33.0 for the borough of Brooklyn, 33.2 for the borough of Queens, and 28.7 for the borough of Richmond. The populations of the five boroughs are estimated as follows: Manhattan, 2,217,294; the Bronx, 300,078; Brooklyn, 1,435,530; Queens, 216,336; Richmond, 75,173.

The most populous borough, then, shows the highest birth rate and the least populous shows the lowest; but beyond this there seems but little tendency of the birth rate to bear a definite ratio to the population. If there were such a ratio established, it would be interesting to speculate as to the fecundity of the boroughs when, as must come to be the case within a few years, the density of population goes on increasing in all but Manhattan, which, let us hope, may at the same time be partially relieved of the "congestion" that is now meeting with the

earnest consideration of many of our philanthropic citizens.

The boroughs of Brooklyn and Queens must soon become full under the influence of new facilities of travel to and from Manhattan; so also must those portions of New Jersey which are within easy reach from the city of New York after the Hudson River has been passed, but the latter, of course, though virtually a part of the city, will probably never be included within its limits. In the Bronx, too, the population is rapidly increasing in density, and there are the contiguous municipalities of Yonkers and Mount Vernon, constantly growing more and more like integral portions of the metropolis. In the borough of Richmond (Staten Island) we may presume there will not soon be seen a vast growth of population, unless additional means of transportation are brought into operation earlier than at present seems probable. That borough, however, in spite of its distance from the chief seat of business, is properly made to figure in the vital statistics of the metropolis, and the same treatment might logically be applied to those districts of New Jersey and Westchester County which we have mentioned did not diversity of jurisdiction interfere with such a course.

### THE TACHYCARDIA OF TUBERCULOUS DISEASE.

In an interesting article published in the *Gazette médicale de Nantes* for March 7th, Dr. Joseph Léquyer remarks upon the frequency with which the subjects of tuberculous disease are affected with a form of tachycardia which does not correspond to a rise of temperature and has no apparent connection with the particular course of the tuberculous affection. It is observed very often in both the acute and the chronic forms of the disease. It occurs at the very onset and even during what may be called the pretuberculous stage, while yet the clinical signs are at the minimum. In other instances it is not until a very advanced period that the pulse becomes very frequent. In many cases the temperature is normal or hardly above the normal point, but the pulse ranges from 100 to 110; if the temperature rises to 100° or 102°, the pulse reaches 130 or 140. There is no invariable rule about this, says the author, but he calls special attention to the discrepancy between the pulse and the temperature. In spite of its acceleration, the pulse generally preserves its perfect regularity; it is exceptional for arrhythmia to exist, though it does occur frequently in the last stages of the disease, also in tuberculous meningitis.

The author then discusses the causes of this tachycardia. He thinks that the patient's nervousness plays a prominent part. Often, too, the acceleration of the pulse is a reflex effect due to excitation of the accelerator nerves. The pulse betrays the suffering of the organism before the pulmonary lesions are much advanced. Tuberculous inflammation of the pneumogastric nerve, which very rarely exists alone, is almost always an accompaniment of peripheral neuritis; then the cause of the tachycardia is clearly apparent. Moreover, there is the action of the tuberculous toxins on the circulatory apparatus; in all tuberculous persons there is a more or less pronounced vascular dilatation, and that of itself is enough to cause tachycardia. If there is, in addition, a slight degree of myocarditis, the heart no longer contracts with its normal force, but endeavors to make up for lack of strength by rapidity of action. In 1889 Maurice Klippel maintained that cardiac amyotrophy was frequently present in tuberculous subjects, and that the consequent overexcitability of the muscular structure of the heart would give rise to tachycardia.

As an early diagnostic sign, when auscultatory signs are wanting, acceleration of the pulse should not be neglected. Lasèque insisted upon it as a distinguishing mark between chloroanæmia and incipient tuberculous disease. Often, he said, the diagnosis would be confirmed when one repeatedly found the pulse above 90 without a febrile temperature. However, the importance of the sign must not be exaggerated. Tachycardia is a frequent symptom, it is due to very diverse causes, and a diagnosis of tuberculous disease is not necessarily to be taken for granted when it is met with. Cardiac affections are often accompanied by tachycardia, and in particular we should bear in mind chronic myocarditis, but the accompanying symptoms will distinguish it. Acute endocarditis is accompanied by dyspnoea and cyanosis, and auscultation will disclose abnormal bruits. In angina pectoris, precordial pain and its radiations are almost constant. Aortitis manifests itself by special souffles. Tachycardia, then, is not the sole sign of these affections.

In prognosis, too, the tachycardia of the tuberculous is often of very great value—not early in the disease, but at an advanced period. Then it indicates intense systemic intoxication, and is particularly observed in patients with extensive lesions; it increases with the advance of the lesions and often attains its maximum in the last stage of the disease. Tachycardia is not simply a diagnostic and prognostic index; it may predispose to very grave complications, such as asystolia. Tuberculous persons with tachycardia often die like the victims of heart

disease; their enfeebled myocardium is forced, their right cavities become distended, and acute asystolia appears. In other cases, in consequence of the tachycardia and the lowering of arterial pressure, cardiac collapse takes place. The pulse, always very rapid, can no longer be counted.

As regards the treatment of this tachycardia, M. Léquey remarks that it is very often futile. Rest is the first thing to be recommended. Cold compresses and ice bags applied over the heart are not so often efficacious as they are for the relief of palpitation. Alcoholic and other stimulating drinks must be interdicted, also overeating, for they increase the frequency of the pulse and predispose to cardiac erethism. In the open air treatment of consumption the tachycardiac patient should not be exposed to high winds or to prolonged action of the sun.

#### THE ÆTIOLOGY OF YAWS.

In 1905 Castellani discovered in smears made from yaws papules an organism which had a morphology closely resembling that of *Treponema pallidum*. His observations were published in the *Journal of the Ceylon Branch of the British Medical Association* for June 17, 1905. The organism, which he named *Spirochæta pertenuis*, he says, is 14 to 20 micra long, is pointed at both ends, and presents a variable number of walls. The name of this organism is now accepted as *Treponema pertenuis*. The observation was confirmed by Wellman, working independently in Angola (*Journal of Tropical Medicine*, vol. viii, p. 345).

Ashburn and Craig (*Philippine Journal of Science*, October, 1907) began the investigation of this organism soon after its first description, having had the good fortune to have some cases referred to them by a native physician. Since the discovery of these cases, yaws, which was formerly thought to be a rare disease in the Philippine Islands, has been found to be common in certain districts on the islands of Luzon and Mindanao. Ashburn and Craig agree in the opinion that *Treponema pertenuis* is the cause of yaws. They have found it constantly present in the serum from yaws lesions. From experiments made on monkeys they find that the inoculation of serum from human yaws lesions containing *Treponema pertenuis* causes yaws in the former animals, and that the organism can be easily demonstrated in the lesions. They further assert that this *treponema* is different from *Treponema pallidum*.

Yaws was originally considered to be a variety of syphilis, modified by climate and by racial peculiarities. In vol. II of the *Transactions of the*

*First Pan-American Medical Congress* there is an interesting description of yaws, or frambœsia, by Dr. George Edmund Pierrez, of Antigua, in which the clinical differences between that disease and syphilis are mentioned. The discovery of an organism which has certain morphological differences from the organism now held by the majority of observers to be the cause of syphilis is an interesting commentary on the accuracy of purely clinical methods. Pierrez, however, considered the disease to be due to a bacterial infection.

## THE HISTOLOGY OF THE YAWS PAPULE.

Specimens of yaws papules have been sent by Ashburn and Craig to Dr. Harry T. Marshall (*Philippine Journal of Science*, October, 1907), who describes their histology. He finds that the lesions are primarily degenerative changes resembling colliquative necrosis, which affects the epithelial structures. This degeneration leads to ulceration. Following the degeneration there is an irregular new formation of epithelium in the form of down growths, and they, in turn, often degenerate. Accompanying these changes, vascular dilatation, œdema, and leucocytic infiltration occur in the corium, with a minor degree of new formation of capillaries and connective tissue. There is no endarteritis, and there are no other changes suggestive of syphilis. At an early stage of the lesion the infiltrating cells are polymorphonuclears and mononuclears in about equal proportions, with many of the latter of the plasma cell type. Sometimes the plasma cells outnumber the polymorphonuclears. Eosinophile cells are abundant. The lesions from monkeys have practically the same histology as those from human sources.

## News Items.

**Changes of Address.**—Dr. H. M. Carey, from Retreat, Pa., to St. Georges, Del.; Dr. William Campbell Posey, to northeast corner of Twenty-first and Chestnut streets, Philadelphia.

**Brooklyn Hospital.**—A department of diseases of the stomach and intestines has been opened at this hospital, with Dr. Dudley Roberts as chief of the service, and Dr. James T. Pilcher as his associate.

**Cumberland County, Me., Medical Society.**—At a meeting of this society, held on Thursday, March 26th, the principal paper of the evening was read by Professor William D. Hurd, of the University of Maine.

**The Northern Medical Association of Philadelphia.**—At a stated meeting of this society, held on Friday evening, March 27th, Dr. Jas. E. Schramm read a paper on the *Diagnosis and Treatment of the More Common Diseases of the Skin*, which was illustrated by lantern slides.

**Buffalo Medical Clinic.**—At the regular monthly meeting, which was held on Thursday evening, March 5th, at the residence of Dr. Hoffman, the principal paper of the evening was read by Dr. F. A. Drake. The subject was *Prophylaxis of the Tubercular Cervical Movement*.

**The Third Cartwright Lecture** will be delivered by Dr. James Ewing, of Cornell University Medical College, on Monday evening, March 30th, at the New York Academy of Medicine. The subject will be *Clinical Forms of Acidoses, Pathological Anatomy and Classification*.

**Richmond, Va., Academy of Medicine and Surgery.**—At a meeting of this academy, held on Tuesday evening, March 24th, Dr. St. George T. Grinnan read a paper entitled *Rheumatic Cycle in Childhood—Tonsillitis, Chorea, Arthritis, and Carditis*, and Dr. M. O. Burke read a paper on *the Uses of the Stomach*.

**The Bill for a New State Hospital for the Insane.**—An act appropriating \$119,250 has been introduced into the Legislature to provide for the purchase of the site of eight hundred and four acres at Congers, Rockland County, N. Y., upon which will be erected a new State hospital for the insane, with a capacity of probably 2,500.

**Association of the Surgeons of the Southern Railway Company.**—A meeting of this association will be held in Birmingham, Ala., on April 28th, 29th, and 30th. A long list of papers and subjects of interest to railway surgeons is shown on the preliminary programme, and the meeting promises to be one of special interest.

**A Banquet in Honor of Dr. Robert Koch** will be given at the Waldorf Astoria on Saturday evening, April 11th, under the auspices of the German Medical Society of New York. The price is \$7 a plate, which includes wine. Admission cards may be obtained from Dr. George Mannheimer, No. 60 East Fifty-eighth street, New York.

**Saratoga Springs, N. Y., Medical Society.**—At a meeting of this society, which was held on Friday, March 20th, the general subject for discussion was *lobar pneumonia*. Papers were read by Dr. Bently on the *etiology and pathology*, by Dr. Resseguie on the *symptoms and diagnosis*, and by Dr. Ledlie on the *treatment of lobar pneumonia*.

**The Mortality of New Orleans, La.**—During the month of February, 1908, there were reported to the Board of Health of New Orleans 736 deaths from all causes, 462 white, and 274 colored. The annual death rate in 1,000 of population was 21.48 for the white population, 35.35 for the colored, and 25.16 for the total white and colored population.

**An Antituberculosis League** has been organized in Lawrence, Mass. Antispitting signs have been placed about the town by the board of health, and an effort will be made to keep the streets cleaner. A class for instruction in the cause and prevention of tuberculosis has been formed which meets once a week. The league is planning to establish a day camp in the near future.

**Medical Inspections of Schools in Chicago.**—During the week ending March 7th the medical inspectors examined 6,828 school children, excluding 313 on account of contagious diseases. Of the total number of exclusions 58 were for measles, 12 for scarlet fever, 7 for whooping cough, 6 for diphtheria, 3 for chickenpox, and 7 for mumps. Vaccination was performed on 890 pupils.

**The Mortality of Portland, Me.**—During the four weeks ending March 7, 1908, there were reported to the Board of Health 98 deaths from all causes, as compared with 108 for the corresponding period in 1907. The annual death rate in 1,000 of population was 21.23. Of the total number of deaths, 23 were from contagious diseases, 17 from pneumonia, and 7 from tuberculosis.

**The Manhattan Medical Society** held a stated meeting on Friday evening, March 27th. Dr. Louis Fougères Bishop reported several cases of early liver symptoms in cardiac diseases, and after the reading of a paper on *Post Mortem Findings in Cases of Eclampsia*, by Dr. John Edgar Welch, a clinical conference was held on *Icterus, Its Significance and Treatment*. A general discussion followed.

**Vacancies in the Staff of the West Side German Dispensary.**—There are two vacancies in the staff of the genitourinary clinic of the West Side German Dispensary, which meets on Tuesday, Thursday, and Saturday evenings, from 7:30 to 8:30. There is a large general service at this clinic, and it offers a good opportunity for special work in cystoscopy, urethroscopy, and urethral catheterization. Applications should be sent to Dr. Abraham L. Wolbarst, 105 East Nineteenth street, New York.

**Buffalo Academy of Medicine.**—A stated meeting of this academy was held on Tuesday evening, March 24th, under the auspices of the Section in Obstetrics and Gynecology. Dr. James E. King read a paper entitled *Transverse Abdominal Incision in Pelvic Surgery, Its Advantages and Limitations*, and Dr. Frank McGuire read a paper entitled *The Treatment of Diffused or Spreading Peritonitis*.

**The Middleton Goldsmith Lecture of the New York Pathological Society** will be delivered by Professor Frank B. Mallory, of Harvard University, at the New York Academy of Medicine, on April 4th, at 8:30 p. m. The subject will be *The Results of the Application of Special Histological Methods to the Study of Tumors*. The lecture will be illustrated, and all who are interested in the subject of tumors are invited to attend.

**Hickman County, Tenn., Medical Association.**—At a recent meeting of this association Dr. Robert P. Wilson read a paper on *Nematodes*, and Dr. Andrew Norris read a paper on *Parasitic Diseases*. The officers of the association for the current year are: President, Dr. Kenneth I. Sutton, of Centerville; vice president, Dr. J. W. Thompson, of Centerville; secretary and treasurer, Dr. John S. Beasley, of Centerville.

**The New Hampshire State Board of Health** announces that it has issued a new compilation of the public health laws of the State, chiefly for the use of health officers, physicians, town clerks, undertakers, and all who have specific duties to perform under these laws. If any interested person fails to receive a copy, one will be forwarded upon application to the board. Dr. Irving A. Watson, of Concord, is the secretary of the board.

**Scientific Society Meetings in Philadelphia for the Week Ending April 4, 1908.**—*Wednesday April 1st*, College of Physicians; Association of Clinical Assistants of Wills Hospital. *Thursday, April 2d*, Obstetrical Society; Medical Society of the Southern Dispensary; Section Meeting, Franklin Institute; Germantown Branch, Philadelphia County Medical Society. *Friday, April 3d*, American Philosophical Society; Kensington Branch, Philadelphia County Medical Society.

**The Pathological Society of Philadelphia** held a stated meeting on Thursday evening, March 26th. A number of card specimens were presented by Dr. E. M. L'Engle, Dr. T. C. Kelly, Dr. A. J. Smith, and Dr. John Funke, and the following papers were read: *A Study of the Colon Aerogenes Group of Bacteria*, by Dr. David Bergey; *A New and Improved Method in the Presumptive Test for *Bacillus coli communis**, by Dr. D. Rivas; *Periarteritis Nodosa*, by Dr. William T. Longcope; *Cysts of the Gallbladder Ducts*, by Dr. R. S. Javerson.

**A Special Tuberculosis Hospital for Oneida County, N. Y.**—The Board of Supervisors of Oneida County, N. Y., has passed resolutions providing for the establishment of a hospital for advanced cases of tuberculosis. An appropriation of from \$65,000 to \$85,000 will be made for the building of a general county hospital and a special tuberculosis hospital, to be erected on the same grounds, but entirely separate from each other. The tuberculosis hospital will have a capacity of twenty-five beds for men and fifteen beds for women.

**Philadelphia County Medical Society.**—The Central Branch of this society held a meeting on Wednesday, March 26th. The evening was devoted to a "symposium on psychotherapeutics" and papers were read as follows: Dr. Charles K. Mills, *Psychotherapeutics, Its Methods, Scope, and Limitations*; Dr. Charles W. Burr, *The Use of the Mental Element in the Treatment of Disease*; Dr. F. X. Dercum, *An Analysis of Psychotherapeutic Methods*. The discussion was opened by Dr. John K. Mitchell, Dr. William G. Spiller, and Dr. Charles S. Parnes.

**A Congress on Physiotherapeutics** will be held in Paris during Easter week, under the auspices of the French Society of Electrotherapy and Medical Radiology, and the Kinetherapeutic Society. The general subject for discussion will be the use of such physical agents as electricity, massage, gymnastics, light, x rays, etc., in the diagnosis and treatment of articular and bony traumatism, and in the treatment of neuritis and myositis. Information regarding the congress may be obtained from the general secretary of the organizing committee, Dr. Leguerrière, 2 rue de la Bienfaisance, Paris.

**The Health of Pittsburgh.**—The following cases of transmissible diseases were reported to the Bureau of Health of Pittsburgh for the week ending March 7, 1908: Chickenpox, 6 cases, 0 deaths; typhoid fever, 25 cases, 7 deaths; scarlet fever, 19 cases, 4 deaths; diphtheria, 9 cases, 0 deaths; measles, 221 cases, 10 deaths; whooping cough, 19 cases, 1 death; pulmonary tuberculosis, 21 cases, 13 deaths. The total deaths for the week numbered 205, in an estimated population of 403,300, corresponding to an annual death rate of 26.43 in 1,000 of population.

**Rochester, N. Y., Academy of Medicine.**—The Section in Public Health, which includes hygiene, climatology, physiology, pathology, bacteriology, and forensic medicine, held a meeting on Wednesday, March 25th. The general subject for discussion was the investigation of medicolegal cases. Dr. E. B. Angell read a paper dealing with the examination of the nervous system; Dr. E. W. Mulligan presented a paper dealing with the surgical aspect of the question; and Dr. W. J. Herriman read a paper on *The Detection of Malingering*. Dr. Franklin W. Bock is chairman of the section and Dr. Bradford A. Richards is the secretary.

**The West End Medical Society of the City of New York.**—The second regular meeting for 1908 will be held at the Belvedere Hotel, on Saturday evening, March 28th, at 8:15 o'clock. Dr. Theron W. Kilmer will read a paper on *The Ambulatory Treatment of Cases of Pneumonia in Infants and Young Children*, which will be discussed by Dr. Charles Gilmore Kerley, Dr. W. B. Hoag, and Dr. Floyd M. Crandall, and a general discussion will follow. The officers of the society are: President, Dr. Le Roy Brown; vice president, Dr. Frank S. Fielder; secretary, Dr. William H. Morrison; and treasurer, Dr. E. V. Hubbard.

**Vital Statistics of New Jersey.**—During the month ending February 15, 1908, there were 3,528 deaths reported, an increase of 147 over the previous month. The principal causes of death were: Typhoid fever, 39; measles, 11; scarlet fever, 50; whooping cough, 24; diphtheria, 67; malarial fever, 1; pulmonary tuberculosis, 375; other forms of tuberculosis, 47; cancer, 126; cerebrospinal meningitis, 24; diseases of the nervous system, 434; diseases of circulatory system, 420; diseases of respiratory system (pneumonia and tuberculosis excepted), 275; pneumonia, 516; infantile diarrhoea, 52; diseases of digestive system, 174; Bright's disease, 220; suicide, 22; all other causes, 651.

**The Philadelphia Neurological Society** held a stated meeting on Friday evening, March 27th. Dr. Alfred Gordon presented a case of superior and inferior poliomyelitis. Dr. S. D. Ingham presented a case of syringomyelia. Dr. Moore presented for Dr. Spiller an atypical case of Friedreich's ataxia. Dr. Lightner Witmer presented a case of aphasia and read a paper on *Certain Cases in which the Psychologist May Assist the Neurologist*. Dr. William G. Spiller read a paper on *Hemiplegia with Rigidity of the Neck Caused by Cervical Myelitis*. Dr. Samuel Leopold read a paper on *Osseous Plaques of the Spinal Pia Arachnoid and Their Relation to Pain in Acromegaly*.

**The Gloucester County, N. J., Medical Society.**—At the meeting of this society, held on Thursday, March 19th, Dr. John M. Swan, instructor in clinical pathology in the Philadelphia Polyclinic and College for Graduates in Medicine, made an address on the *Diagnostic Significance of Leucocytosis*. The address was supplemented by a microscopic demonstration of specimens showing leucocytosis of varying extent. Dr. Pfeiffer, of the German Hospital, Philadelphia, reported an interesting case. There was a discussion on medical legislation as affecting the State of New Jersey. The scientific business was followed by a dinner at Paul's Hotel. About thirty-five members and guests were present.

#### Society Meetings for the Coming Week:

**Wednesday April 1st.** Society of Alumni of Bellevue Hospital, New York; Harmon Medical Association, Elmira, N. Y.; Academy of Medicine.

**Thursday April 2d.** New York Academy of Medicine, Danville, N. Y.; Medical Association.

**Friday April 3d.** New York Academy of Medicine (Section in Surgery); New York Microscopical Society; Gynecological Society, Brooklyn, N. Y.; Manhattan Clinical Society; Practitioners' Society of New York.

**The Mortality of Chicago.**—According to the report of the Department of Health for the week ending March 14, 1908, there were during the week 639 deaths from all causes, as compared with 684 for the corresponding week in 1907. The annual death rate was 15.38 in 1,000 of population. The principal causes of death were: Apoplexy, 11; Bright's disease, 31; bronchitis, 20; consumption, 78; cancer, 15; convulsions, 7; cerebrospinal meningitis, 3; diphtheria, 11; heart diseases, 53; influenza, 10; intestinal diseases, acute, 50; measles, 10; nervous diseases, 16; pneumonia, 120; scarlet fever, 8; suicide, 9; typhoid fever, 7; violence, other than suicide, 44; whooping cough, 2; all other causes, 139.

**Vital Statistics of New York.**—According to the report of the Department of Health of the City of New York, there were during the week ending March 14, 1908, 1,604 deaths from all causes, as compared with 1,670 for a corresponding period in 1907. The annual death rate was 18.92 in 1,000 of population. Of the total number of deaths, 826 were in the borough of Manhattan, 125 in the Bronx, 557 in Brooklyn, 69 in Queens, and 27 in Richmond. The death rate for the borough of the Bronx was 19.91, which was the highest for the five boroughs, and Brooklyn was second with a death rate of 19.47. The death rate of Manhattan for the week was 18.70, of Richmond 18.37, and of Queens, 15.48. There were 578 marriages recorded during the week, 2,317 births, and 132 stillbirths.

**Personal.**—Dr. Frederick L. Benton, a surgeon in the United States Navy, is the first American physician to receive a degree in medicine and science at the University of Havana. Dr. Benton is now regimental surgeon of the marine regiment in Cuba. The examination was in Spanish.

Dr. Arthur Keith, lecturer on anatomy at the London Hospital Medical College, has been appointed conservator of the Museum of the Royal College of Surgeons.

Mr. Peter White, of Marquette, Mich., has given \$1,000 to the library of the University of Michigan, to be used in purchasing rare medical books.

Dr. Ennion G. Williams, of Richmond, has been appointed health commissioner of the State of Virginia.

#### Infectious Diseases in New York:

*We are indebted to the Bureau of Records of the Department of Health for the following statement of new cases and deaths reported for the two weeks ending March 21, 1908.*

	—March 14.—		—March 21.—	
	Cases.	Deaths.	Cases.	Deaths.
Tuberculosis, pulmonary	434	191	507	168
Diphtheria	322	55	397	53
Measles	1,043	27	1,007	33
Scarlet fever	942	44	901	37
Smallpox	1	—	—	—
Varicella	187	—	218	—
Typhoid fever	31	9	27	4
Whooping cough	20	2	21	3
Cerebrospinal meningitis	12	12	10	9
Totals	3,598	349	3,748	307

**The Health of Philadelphia.**—During the week ending March 7, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Malarial fever, 1 case, 0 deaths; typhoid fever, 85 cases, 9 deaths; scarlet fever, 74 cases, 5 deaths; chickenpox, 32 cases, 0 deaths; diphtheria, 85 cases, 18 deaths; measles, 28 cases, 7 deaths; whooping cough, 19 cases, 5 deaths; pulmonary tuberculosis, 139 cases, 73 deaths; pneumonia, 94 cases, 93 deaths; erysipelas, 12 cases, 0 deaths; puerperal fever, 8 cases, 7 deaths; cancer, 23 cases, 23 deaths; German measles, 3 cases, 0 deaths; mumps, 28 cases, 0 deaths. The following deaths were reported from other transmissible diseases: Tuberculosis other than tuberculosis of the lungs, 4; diarrhoea and enteritis, under two years of age, 17; cerebrospinal meningitis, 1. The total deaths numbered 571, in an estimated population of 1,532,738, corresponding to an annual death rate of 19.31 in 1,000 of population. The total infant mortality was 119; under one year of age, 87; between one and two years of age, 32. There were 35 stillbirths, 21 mumps, 14 measles.

**Benedictine Sanitarium and Hospital, Kingston, N. Y.**—The annual meeting of the board of directors and the staff of this institution was held on Friday evening, February 28th. Dr. Charles Phelps, of New York, was re-elected president of the staff, and Dr. Mary Gage-Day was elected secretary, to take the place of Dr. Robert R. Thomp-

son, deceased. The out of town consulting staff remains the same as last year, and the local staff will be composed of the following: Attending surgeons, Dr. Mark O'Meara, Dr. James L. Preston, Dr. E. E. Norwood, Dr. Alexander A. Stern, Dr. W. J. O'Leary, Dr. L. K. Steele; attending physicians, Dr. George H. Van Gaasbeek, Dr. B. W. Maben, Dr. Harvey C. Keator, and Dr. Adelbert H. Mambert; consulting physicians, Dr. W. E. E. Little, Dr. C. F. Keefe; attending physician and surgeon for the eye, ear, nose, and throat, Dr. Aden C. Gates; attending bacteriologist, Dr. Charles W. Crispell; and attending gynecologist, Dr. Mary Gage-Day.

**An Antituberculosis Campaign in Rochester, N. Y.**—The Public Health Association of Rochester, N. Y., has made arrangements for a series of meetings to be held during the week of March 30th for the purpose of discussing the question of tuberculosis. The traveling tuberculosis exhibit of the State Department of Health will be open to the public daily from 1 to 10 p. m. at Convention Hall, where the meetings will be held, and illustrated lectures will be delivered daily at 3 and 8 p. m. The campaign will be opened on Monday, March 30th, by a joint meeting of the Public Health Association with the medical and dental societies and the ministerial associations of Monroe County. Dr. Lewis Gregory Cole, of New York, will deliver an illustrated lecture on Radiography in the Diagnosis of Tuberculosis, and Dr. John B. Huber, of New York, will deliver an address on The Diagnosis of Incipient Tuberculosis. Among those who will deliver addresses during the week are Dr. C. W. Dodge, city bacteriologist of Rochester, Dr. J. Franklin Bock, Dr. Albert C. Snell, Dr. Francis E. Fronczak, of Buffalo, Dr. Arthur G. Root, of Albany, and Dr. S. A. Knopf, of New York.

#### Meetings of State Medical Societies for the Month of April, 1908:

Medical Association of the State of Alabama, annual meeting at Montgomery, April 21st.

Arizona Medical Association, annual meeting at Tucson, April 20th.

Medical Society of the State of California, annual meeting at Coronado, April 21st, 22d, and 23d.

Florida Medical Association, annual meeting at Ocala, April 15th.

Medical Association of Georgia, annual meeting at Fitzgerald, April 15th.

Louisiana State Medical Society, annual meeting at Alexandria, April 28th, 29th, and 30th.

Mississippi State Medical Association, annual meeting at Natchez, April 14th.

Medical and Chirurgical Faculty of Maryland, annual meeting at Baltimore, April 28th, 29th, and 30th.

South Carolina Medical Association, annual meeting at Anderson, April 16th, 17th, and 18th.

Tennessee State Medical Association, annual meeting at Knoxville, April 14th.

**Philadelphia Bureau of Health Statistics.**—During January, 1908, in the Division of Medical Inspection of the Philadelphia Bureau of Health, 3,902 inspections were made exclusive of schools; 654 fumigations were ordered; 43 cases were referred for special diagnosis; 4,422 visits were made to schools; 349 children were excluded from school; 311 cultures were taken; 133 injections of antitoxine were given; and 412 persons were vaccinated. In the Division of Vital Statistics 3,165 deaths, 2,921 births, and 1,178 marriages were reported. In the Division of Milk Inspection 8,561 inspections were made of 196,634 quarts of milk, of which 315 quarts were condemned. Seven specimens were tested chemically and 984 microscopically. In the Division of Meat and Cattle Inspection 3,695 inspections were made; 83 places were found unsanitary; 214 pieces of dressed meat were condemned; and 868 postmortem examinations were made with 44 condemnations. In the Division of Disinfection 312 fumigations were done for scarlet fever, 440 for diphtheria, 135 for typhoid fever, 222 for tuberculosis, 545 for miscellaneous diseases, and 17 schools were fumigated. In the Bacteriological Laboratory 1,396 cultures were examined for the presence of bacillus diphtheriae; 510 specimens of blood were examined for the serum diagnosis of typhoid fever; 984 specimens of milk were examined, 208 specimens of sputum were examined; 5 disinfection tests were made; and 3,224,500 units of antitoxine were distributed. In the Chemical Laboratory 97 analyses were made.

## Pith of Current Literature.

### THE BOSTON MEDICAL AND SURGICAL JOURNAL.

March 19, 1908.

1. Opening Address of the President before the New England Pædiatric Society,  
By THOMAS MORGAN KOTCH.
2. The Serum Treatment of Epidemic Cerebrospinal Meningitis,  
By CHARLES HUNTER DUNN.
3. The Use of Fat Free Milk in Infant Feeding,  
By CHARLES W. TOWNSEND.
4. The Use of the Röntgen Ray in the Study of Diseases of Children,  
By ARIAL W. GEORGE.

2. **The Serum Treatment of Epidemic Cerebrospinal Meningitis.**—Dunn has used Flexner's antiserum, since November, 1907, in fifteen cases of epidemic cerebrospinal meningitis, in all but one of which the diagnosis was confirmed by the finding of the diplococcus intracellularis in the cerebrospinal fluid. Of these patients eight have completely recovered, two died, and five are still under observation. The eight patients who recovered are all perfectly well, having been left with no sequelæ of any kind, an unusually favorable result in this disease. The two fatal cases were both chronic cases, in which the disease had run considerable time before coming under his observation. Of the five cases which are still pending, four patients are now convalescent and will undoubtedly recover; the other is a chronic case, in which the outcome is dubious. The eight patients, to whom the serum was given early in the disease, showed a very marked, even startling, improvement immediately following the giving of the serum. In four of these cases there was an immediate and permanent fall of temperature, exactly resembling the crisis of a pneumonia, which was accompanied by a complete and permanent return of the mental condition to normal, complete and permanent disappearance of headache, and followed by rapid disappearance of rigidity of the neck and all other signs. Two of these cases, in twelve hours after the first dose, returned from a condition of complete unconsciousness to one of absolutely normal mental condition. In the other four cases, the temperature fell to the normal by a fairly rapid lysis, accompanied by rapid improvement in the mental condition and disappearance of symptoms and signs. In two of these, there was a rapid change from a condition of active, almost violent, delirium to one of normal mentality. The conclusions he reaches are that the use of the antiserum does no harm. Our author states that he has used it in larger doses than any of the other investigators. In no case was there any sign of bad effect, and in two cases he injected it into the spinal canal without the previous withdrawal of fluid without any sign of bad result from increased intradural pressure. He would not recommend the use of this procedure without great caution. He has never seen nor heard of a case proved by lumbar puncture to be true epidemic meningitis which aborted or terminated by sudden crisis at an early stage. The recovery by crisis and the rapid improvement followed by recovery immediately following the giving of the antiserum, in so large a proportion of this series of cases, is, he believes, strong evidence of the favorable specific effect of this treatment. The completeness of the recovery

of the cases in this series is another very important feature. The most important point suggested by the results of the use of the Flexner serum, in this series of cases of epidemic cerebrospinal meningitis, is the advantage to be gained by giving it early in the course of the disease. Not only did all the patients to whom it was given early recover, but all those cases in which its use was followed by a marked immediate improvement were cases in which it was given within the first few days of the disease; and in two of these earlier cases, the disease was apparently completely aborted by one dose of the antiserum. He thinks the results of the Flexner antiserum in these cases are sufficiently good to afford a very strong basis of hope that this treatment will prove of great value in the treatment of cerebrospinal meningitis, a value commensurate with that of antitoxine in diphtheria.

3. **The Use of Fat Free Milk in Infant Feeding.**—Townsend thinks that, while fat is very necessary to the normal infant, it is more often given in excess than is generally supposed. Excess of fat may cause one or more of a number of symptoms, as, for example, constipation, white and "curdy" stools, a ravenous appetite with atrophy, convulsions. In gastrointestinal disturbances it is desirable to exclude fat. The proteids of undiluted fat free milk appear to be remarkably well borne even by young infants, and there is an absence of so called curds from the stools.

### THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

2. **The Home Treatment of Pulmonary Tuberculosis.**—Brown says that in the treatment of tuberculosis a proper regulation of rest and exercise is the most important point. Absolute rest must be enforced during and for some time after the existence of toxæmia. The exercise must begin after nearly normal weight is gained, and very gradually, so as not to produce toxæmia. It is best that the exercise be begun so that there is an interval of a week or more between two exercise periods. The second important factor is good air. Fresh country air, or a climate which is not too warm, and at an altitude of not more than 1,000 to 1,500 feet, is desirable. Air should be circulating through the patient's room all the time. It is of some benefit, perhaps, in some instances, for the patient to live out of doors. This is of little importance, however, when compared with the significance of the rest and exercise. The third important factor is good food. The patient should have three good meals a day, and between each two meals a lunch of egg and milk.

Forced feeding is not necessary, but good feeding is essential. It should also be repeated that consumptives are curable, and that it is being demonstrated every day. The tuberculous patient must, however, be treated as though he were really sick, just as sick as if he had some acute disease, as scarlet fever, typhoid, or pneumonia. In tuberculosis, where there are signs of progress of the disease, it is of far more importance to keep the patient quiet than to force him to eat unusually large quantities of food, or keep him out of doors all the time, or give him large quantities of codliver oil, creosote, or other drugs.

**3. The Management of the Sexual Factor in Tuberculosis.**—Peters remarks that the problem of how to regulate sexual intercourse is one of the most difficult in phthisis therapy, and that it is correspondingly important. Some physicians think it is erroneous to hold that consumptives are more prone to sexual excitement than healthy individuals; that we are impressed in rather a disproportionate way because the erethism which some consumptives admit is surprising and grotesque, when this disease is, in itself, so enervating and so exhausting. At the other extreme are those physicians who consider the phenomenon a very prevalent one. The latter view is apt to be held by those of our colleagues who do a great deal of dispensary work among the poor in large cities, and among the victims of alcoholism and prostitution, which factors are so often either predisposing to or coexisting with consumption. Between these two extremes of opinion, however, are ample data to show that the tendency to abnormal sexual excitement is so frequent among consumptives as to require the careful attention of the physician. What are the reasons for such abnormal erethism in consumptives? There is, first, the lack of occupation, which is either enforced by the physician as one of the fundamental principles of phthisis therapy, or which has naturally come about through the patient's weakness and hesitancy of employers to engage a sick man. Enforced idleness follows, and this oftentimes leads to unwholesome introspection. Then, the temperature in consumption, no doubt, excites erethism. The toxins generated by the tubercle bacillus and in the mixed infections have a similar influence. Then, there is the forced feeding essential to the cure; the eating of raw eggs and rich red meats; also the stimulating life in the open air and sunshine, and the tonics—such as strychnine—which we find adjunct to the cure. Besides, some consumptives feel that their disease dooms them to an early death, and "Drink and be merry, for tomorrow you die," becomes their life philosophy. The physician should represent to the patient that the treatment which is emphasized, rest, nourishing food, outdoor life, and the use of tonics and stimulants, is essential, in order that the exhausted organism may fight and destroy the forces of disease which so grievously beset it; and that if the body becomes enervated by excesses and acts tending to deplete the strength, recovery can not be hoped for. We must appeal to the fair mindedness of the consumptive, stating to him that the spermatic fluid contains the fertilizing sperm up to the day of death; that children have often been born long after the death of consumptive fathers; that such children, because of the physiological poverty of their sick

progenitors, come into the world with the most unfair and cruel handicap of an abnormal heredity. The well husband of a consumptive wife should have his honor and real affection for her appealed to, not to make her pregnant; since in such cases the saddest of all deaths is deplorably frequent. Finally, consumptives who consult physicians with regard to their marriage prospects should be most earnestly counseled not to take the step until they are entirely cured.

**6. The Endemic Occurrence of Cancer in Fishersville, Va., and Vicinity.**—Tynes states that there has been an endemic of cancer in Fishersville and vicinity for a number of years. At one time there was a high mortality from cancer among those who lived in the community, by no means confined to families, succeeded by a period in which there was comparative immunity to the disease. This period is followed by a decade in which there is a recurrence of the disease, causing a higher mortality in his own practice than that of any other disease. In a nearby city, within an area a little larger than a city block, twelve cases have developed during the last seven years, and this in a city in which the physicians inform the writer they have seen very few cases of cancer. He believes sufficient evidence has been submitted to show that the high mortality from cancer in Fishersville and vicinity is not due to a fortuitous occurrence, but is due to an infectious organism transmitted directly or by means of a host. Such a theory does no violence to the views of those who believe in a hereditary predisposition to cancer.

By L. PIERCE CLARK.

**1. A Study of Four Hundred Cases of Epithelioma, in Private Practice, with Remarks on Treatment and Results.**—Bulkley and Janeway observe that the most frequent form of cancer which the dermatologist is called on to treat is, both pathologically and clinically, quite a different growth in its relatively benign course from the usual conception of cancer. It occurs chiefly about the face, in places where radical operative measures are apt to produce serious deformities, which very materially add to the patient's discomfort. While the experience of thirty-five years demonstrates that many cases can be permanently cured by caustic pastes, these are at times disappointing and may lead to an aggravation of the trouble. The curette cannot be depended on alone, but requires additional destructive agents to the base left after operation. By the proper use of the x ray we have a safe, and, in cases that have not been grossly neglected or mal-

treated, a sure method of cure, with the least amount of deformity. In cases where knowledge and experience show that these lighter measures are not likely to avail in checking the course of the disease, recourse should certainly be made to complete surgical removal, as this has been shown to be permanently successful in a reasonable proportion of cases.

**4. The Diagnosis and Treatment of Early Ectopic Gestation.**—Brothers observes that in the attempt to make a diagnosis of ectopic gestation a careful previous history is desirable. The age of the patient, period of married life, nature of menses previous to and since marriage, the number of children or abortions, including their nature and post partum ailments—all should be inquired into. The possibility of gonorrhœal or puerperal infections, of endometric or annexal disease should be sought for in such previous history. Previous operations—especially curettages—should be noted. In taking note of the present illness, the mode of onset—particularly if an attack of syncope is referred to—should be analyzed. Symptoms pointing to the possibility of an early pregnancy and an impending or an incomplete abortion are of peculiar value in the history of the case. The three original subjective symptoms are, irregular uterine bleeding, cramps, or pelvic pains, and fainting spells, and should direct the attention of the physician to the possibility of ectopic gestation, the diagnosis of which can then be substantiated or negatived by the physical examination. Besides these there are minor symptoms, such as rectal and bladder symptoms, etc. Distinctive diagnosis must take into consideration ordinary uterine pregnancy with the usual symptoms of impending or incomplete abortion. Diagnosis has been made of cholelithiasis or appendicitis; a fibroid uterus can usually be distinguished by the history, and the stone like hardness of the one or more tumors present. Cystic ovarian tumors and intraligamentary cysts sometimes lead to errors, particularly when they are complicated by uterine pregnancy, or are wedged in the pelvis, or are twisted on their pedicles. The cystic feel, the globular contour, the lateral situation, and the mobility of ovarian cysts suffice ordinarily to distinguish them. Pelvic abscess may at times strongly simulate an ectopic gestation. In case the presence of a febrile movement, exquisite tenderness over the mass, a markedly increased leucocytosis and polynuclear count fail to clear up the diagnosis the introduction of an aspirating needle will definitely settle the matter.

**5. Treatment of Hyperphonia (Stuttering and Stammering) by the General Practitioner.**—Scripture remarks that the general therapeutic indications include treatment of any nose or throat trouble that may be present, building up the general health, etc. It sometimes does occur that an operation for adenoids, for pharyngitis, or for anything else is followed by complete cure of the stuttering, but this is purely a result of the patient's belief that the operation was intended for his disease. Every case of hyperphonia requires special therapeutic procedures. His own experience has shown the following ones to be most effective:—Introducing the index into the voice, developing expressiveness, detracting

from the compulsive idea. The author explains his methods of procedure, and asserts that they will permanently cure three quarters of the stutterers and stammerers, if practice is given at first as often as possible and then at steadily increasing intervals. The treatment should last for fifteen minutes to half an hour. At first it should be given at least three times a week, then twice a week, then once a week, then once in two weeks, and so on. The patient should be warned that if he stops suddenly his trouble will probably return. The care of the general health and the examination of the mind, nerves, and breathing organs are so important that only a physician can be considered competent to advise. For a case of stuttering the parent should send the child directly to the doctor. Unfortunately the doctor is very likely to prescribe a tonic and to say that the trouble will pass away in the course of time. Sometimes it does; generally, however, it steadily becomes worse, and the child's companions and parents by their taunts or nagging or scolding make his life a condition of torture to which Hades would be a relief. Hyperphonia is a serious disease. The patients do not die of it directly, but their lives are so filled with suffering that most of them wish they could. That some of them are cured by outsiders does not alter the fact that most of them are not.

#### 1. Pulmonary Tuberculosis in Children.—

Young states that the various authorities differ widely as to the frequency of pulmonary tuberculosis in infancy and childhood. French observers assert that fifteen per cent. of school children have tuberculosis in some form, while English and German observers make it less than two per cent. Of 337 children with cough and wasting examined by the writer, only forty-five showed signs of definite tuberculous involvement of the lungs. As regards the manner of infection of children with tuberculosis, there are five possibilities—(1) transmission from the mother to the fœtus in utero; congenital or hereditary tuberculosis; (2) inoculation of wounds; inoculation tuberculosis; (3) inhalation of tubercle bacilli in dust, vapours, or milk; (4) by swallowing bacilli in food, especially milk; ingestion or enterogenous tuberculosis; and (5) infection through the ear, Eustachian tube, or tonsil. The first two and the last of these may be dismissed as exceedingly rare, and the problem is narrowed down to the relative frequency of inoculation and of infection.

enous tuberculosis. The question is not yet settled, but it seems probable that the first is more common. As regards predisposing causes, the condition of infancy itself is one of high susceptibility, the resisting power being low, and only a very short exposure being required to produce the disease. As regards the sites and distribution of the lesions, attention is called to the great frequency with which in children the bronchial or tracheobronchial glands are involved, either primarily, or secondary to pulmonary infection. Again, the lesions in the lungs do not, as a rule, follow the well known laws of spread from apex downward, they being usually diffuse and very often most marked at the root of the lungs. The cases may be classified as follows: (a) Tuberculosis of the tracheobronchial glands; (b) acute miliary tuberculosis; (c) acute caseous tuberculosis; and (d) chronic or fibrocaceous tuberculosis. Fibroid tuberculosis does not exist in children. Cavities, while difficult to recognize clinically in children, are not uncommon; usually they are small and of recent origin. They may contain a sequestrum of broken down lung tissue. Pleurisy is common and may lead to parietal and interlobular adhesions. The diet should be liberal, but children do not stand overfeeding well. Drugs are but little needed. Tuberculin should only be used where the disease is strictly localized, and then in very small doses. The aims of the practitioner should be in the first instance to prevent infection; failing this, to establish the diagnosis as early as possible, and to employ every available means of improving the general health of the child, with the object of improving its protective powers. Under such conditions the outlook in a considerable proportion of the cases is distinctly favorable.

**2. Surgical Tuberculosis.**—Low sums up the modern treatment of surgical tuberculosis as follows: 1. In all cases "open air treatment" should be organized to meet the circumstances and requirements of the particular case. 2. The patient's powers of resistance to the disease should be periodically measured by suitable blood examination. 3. Where the resistance is found to be low and there is no evidence of excessive autoinoculation, use should be made of inoculations of Koch's new tuberculin, in doses that are accurately controlled, both as regards their amount and repetitions, by examination of the blood. 4. For patients in whom there is evidence of excessive autoinoculation, absolute rest with, in the case of a limb, absolute fixity of the diseased part, should be prescribed. 5. In the cases of circumscribed tuberculosis, efforts should be directed to increase the circulation through the infected area. 6. Operative procedures should be directed to the removal of the inert material, whether caseous glands, carious bone, or collections of pus, and allowing the access to the infected area of healthy lymph. The necessary operations should be conducted with the most scrupulous asepsis.

**7. Typhoid Carriers.**—Dean reports the case of a man who had typhoid fever twenty-nine years ago, and who still has living typhoid bacilli constantly present in his stools. Our conception of typhoid fever has been materially altered by the observations of Förster. It is now held that the bacilli are pres-

ent in the blood during the incubation period, and even before they can be found, antibodies are present. The bacilli only appear in the faeces during the first and second weeks. The bacilli therefore do not multiply when first taken into the alimentary tract, but find their way through its walls into the blood. At a very early stage they gain entrance into the liver and bile, and set up inflammation in the bile ducts and gallbladder. Normal bile is not a good medium for their growth, but when the albuminous secretion due to the typhoid inflammation is added to it, it becomes an excellent medium, and the bacilli grow freely in the gallbladder and pass out in large numbers, but intermittently, into the small intestine. This explains the irregular occurrence of the bacillus in the faeces. In most cases, with recovery the inflammation in the bile ducts and gallbladder also ceases. But in about two per cent. of the cases this cholecystitis typhosa becomes chronic, and the bacillus continues to multiply in the gallbladder for months or years, and to be thrown out into the gut, and on out with the faeces. The gallbladder is then a normal habitat of the typhoid bacillus. These cases are the so called "typhoid carriers"—constant sources of danger to the public. They account for the sporadic cases, the origin of which has been so puzzling. Gallstones occur in many cases, and, just as three fourths of the cases of biliary calculi in general occur in women, so three fourths of the typhoid carriers are also women. In most of the cases the blood serum possesses marked agglutinating properties. This may be useful as a means of detecting such cases in a community. There is an enormous reduction in the total number of microorganisms present in the faeces, the normal inhabitants having been altogether or largely replaced by the typhoid bacillus.

7. Seven Years' Experience of the Finsen Treatment, By J. H. SEQUEIRA.
8. A Case of Egg Poisoning, By A. T. SCHOFIELD.
9. Motoring Notes, By C. T. W. HIRSCH.

**1. Surgery of the Spinal Cord.**—Armour, in the first of the Hunterian lectures on the above mentioned subject, discusses the congenital malformation known as spina bifida. Under the terms "rachischisis" and "spina bifida" are included the principal forms of congenital defects of the spine. Both are characterized by a deficiency in the vertebral arches, but distinguished by the presence or absence of a well developed spinal cord. Total rachischisis includes all cases in which the vertebral canal is open from end to end; the cord is always rudimentary or atrophic, split open or bifid. It may be entirely absent (amyelia). This form

occurs much more often with anencephaly. Partial rhachischisis includes cases in which the defective development affects only a part of the column. It may or may not be associated with the presence of a hernia, the condition being then known as meningocele, meningomyelocele, or syringomyelocele, according to the relation of the spinal cord to the sac. In spina bifida occulta there is no external evidence of the defective development of the vertebral column, normal skin covers the affected area of bone, and no cyst projects through the bony defect, which is usually closed in by a thick fibrous membrane. Spina bifida may be accompanied by other malformations of the spinal cord, and clubfoot, double or single, is a common complication. Congenital dislocation of the hip, hare lip, cleft palate, etc., also occur. Spina bifida occurs about once in 1,000 births, and both sexes are equally affected. While it may appear in any portion of the spine, the lumbosacral region is most frequently affected, the sacral being next in order of frequency. This is probably due to the fact that the medullary groove is latest in closing here to form the neural canal. The diagnosis is usually easy, except where the tumor makes its exit through a defect at the sides of the spinal column and forms an intraabdominal cyst. Here it may be impossible to distinguish it from other abdominal cystic tumors. It is often impossible to distinguish clinically between the various forms of spina bifida, myelocystocele, meningomyelocele, and meningocele. The treatment of rhachischisis, or complete lack of union, is hopeless. Spontaneous cure in spina bifida does take place occasionally; cure may also follow rupture and ulceration, but these processes are also the most common causes of death. Protection against rupture and abrasion should be maintained in all cases. Simple tapping should never be resorted to as a curative procedure; the fluid returns quickly, and sudden death sometimes occurs. The only forms of treatment to be recommended are palliation or excision. Palliation is obtained by the use of some form of shield used in conjunction with a broad abdominal belt. But excision is now universally adopted, except in absolutely inoperable cases. The indications to be met are the removal of the sac and the closure of the cleft. The simplest and quickest technique is the best; no drainage should be used, and special attention paid to asepsis. The operation should be done as early as possible. The chief contraindications are marasmus and hydrocephalus. The prognosis without operation is absolutely bad.

5. **Hernia of the Iliac Colon.**—Stoney states that hernia of the iliac colon may occur in at least three distinct ways: 1. It may be drawn into or through the inguinal canal by an extra attachment of the gubernaculum testis. 2. It may be drawn down by a protrusion of the peritonæum covering it in the formation of the sac of an ordinary hernia. 3. There may be a giving way or lengthening of the supporting apparatus of this portion of the intestine and a subsequent protrusion of it by the expansive action of the abdominal muscles and diaphragm. The operative treatment varies according to the condition of the sac, where this is com-

plete it will not differ from the radical cure of any other inguinal hernia; but where the sac is incomplete the difficulties in the way of a radical operation may be great. The two main points to be attended to in the operation are, first, not to interfere with the blood supply of the loop of intestine, either while trying to separate adhesions or while dissecting up the posterior wall of the sac above the loop of intestine from the surrounding tissues, for this would mean almost certain gangrene of the gut; and, secondly, an attempt should be made to stitch the cut edges of the peritoneum after the main part of the sac has been cut away and the gut and remainder of the sac together have been reduced inside the abdominal cavity.

6. **Intussusception.**—Fitzwilliam's paper is based on a study of one thousand cases of intussusception. In the first part he brought forward arguments to prove that the so called ileocolic variety of intussusception is nothing more than an enteric invagination which has commenced in the lower part of the ileum and passed through the valve. In the second he deals with the classification of intussusception, the relative numbers of each variety, and gives a short account of some of the rarer forms. The seasonal incidence of the condition is marked. The number is low during January and February, and then suddenly rises to the maximum in March. From April to September the fall is gradual, with a slight rise in October and November, and a sharp rise in December. The remarkable thing is the steady fall in the number of cases during those months in the summer and early autumn when the intestinal disorders of infants are most marked. The rise during December is probably connected with the dietary peculiar to Christmas time. The marked rise during March is associated with Easter, at which time older children are accustomed to take candy and other indigestible food, a share of which is given to the infants. Of 788 cases, sixty-eight per cent. were boys and thirty-two per cent. girls. This disproportion between the two sexes becomes still better marked in children under twelve years of age, the ratio between boys and girls being then three to one. Whatever may be the explanation of this, it is probably not due to any difference in anatomical relationships, since the preponderance is most marked during the early years of life before any sexual differences become marked. Indeed, the sex incidence rather favors a dietetic origin of the affection; male children, being larger and stronger, are given more food than those of the opposite sex. Want of coordination of the intestinal movements may be an important factor in the production of intussusception. It is only a factor, for it cannot be the sole cause. From the diminution in the numbers of intussusceptions during the months when epidemic diarrhæas are at their height, it may be supposed that the more violent forms of intestinal stimulation are so potent that any invagination which has taken place is reduced by the rapidity of the intestinal movements long before it has become really established. The age incidence, the effect of the seasons, and the disproportion between the sexes all seem to point to a dietetic rather than to an anatomical causation of the disease.

12. Casuistic Contribution to the Importance of the Radiological Investigation of the Colon, By WIESNER.
13. Concerning Treatment of Placenta Prævia by Vaginal Cesarean Section, By RÜHL.
14. Concerning a Case of Traumatic Luxation of the Right Ulnar Nerve, By QUADFLIEG.
15. A Glass Bulb Filled with Physiological Salt Solution Ready for Use as an Infusion, By BRENNER.
16. The Restriction of Laparotomy by Vaginal Methods of Operation, By FLATAU.
17. Are the Objections to the Legal Regulations Concerning Sexual Perversions Scientifically Tenable? By WEYGANDT.
18. Obituary of Oskar Lassar, By JESIONEK.
19. The New Regulations as to Board in the City Hospital in Dresden, By SCHANZ.

1. **Oponins as a Means of Distinction and Identification of Pathogenic Forms of Bacteria.**—Schottmüller and Much state that the honor of the discovery of oponins belongs to Russia at the hands of Metchnikoff, but acknowledge the indubitable service of Wright and his followers in the discovery of a practicable method for their determination. They now advance the theory that if several kinds of bacteria are to be found in a sick man and yet only one of them is influenced opsonically by his serum it is extremely probable that this microorganism is alone the originator of the sickness. When several kinds of bacteria are thus influenced the case is one of mixed infection. They present first the results of their investigations in cases of acute gastritis, gastroduodenal catarrh, and gastroenteritis, then a case in which the bacillus coli communis played a passive rôle, then cases of epidemic cerebrospinal meningitis, in all of which the offending microorganisms seemed to be pointed out.

3. **Cobra Poison and the Red Blood Cells.**—Sachs disagrees with the conclusions recently published by von Dungern and Coca to the effect that the cobra venom contains a constituent rendered specially active by serum complement which unites with the red blood corpuscles.

6. **Graphic Registration of the Blood Pressure.**—Jaquet describes an instrument which he has devised and named the phrygmotograph that is to be applied to the wrist of the patient in such a way that the pulsations of the radial artery will be transmitted to a registration needle, which will record the blood pressure at the time.

8. **Inhalations of Saponin in Diseases of the Upper Air Passages.**—Zickgraf states that he has obtained excellent results in nasal conditions varying from rhinitis sicca to ozena from the inhalations of the fumes of saponin dissolved in hot water to the strength of one or two per cent.

12. **Radiological Investigation of the Colon.**—Wiesner reports a case in which an interval operation for appendicitis was successfully performed, but was followed in about four weeks by attacks of acute colitis occurring about every three weeks. Radiological examination revealed the fact that the cæcum and a portion of the descending colon were bound down by adhesions, and that a small blind pouch had become formed in this portion of the intestine. This condition was relieved by another operation, and a radiological investigation three months later showed that the intestine was in good position. There had been no recurrence of the attacks of acute colitis five months after the operation.

13. **Treatment of Placenta Prævia by Vaginal Cesarean Section.**—Rühl reports two cases of placenta prævia, in which he performed Cesarean section through the vagina. He strongly advocates this method of treatment, although formerly he was inclined to condemn Cesarean section, either abdominal or vaginal, as not indicated in such cases.

14. **Traumatic Luxation of the Right Ulnar Nerve.**—Quadflieg reports a case of luxation of the ulnar nerve in a man, thirty-five years old, who had received an injury to the arm. The nerve was laid bare and attached with silk threads to the tendon of the triceps, the sutures passing through the perineurium. The pain and other symptoms, which are graphically described, disappeared immediately as the result of the operation. This method of fixation of the nerve seems to have worked better in this case than the method of resection of a part of the nerve on the assumption that it has been overstretched.

1. **Previous Condition of Victims of Railroad Accidents.**—Balthazard discusses the influence that should be exerted by the previous condition of the victim upon the indemnity for injuries received.

March 4, 1908.

1. Electrolysis in the Treatment of Angiœmata, Particularly of Angiœmata of the Parotid Region, By F. REDARD.
2. Evolution, Forms, and Treatment of Bronchointestinal Autoinfection in the Newly Born, By P. LONDE.

1. **Electrolysis in the Treatment of Angiœmata.**—Redard reports with illustrations a case of angiœma of the parotid region in a child of eleven months which he successfully treated by means of electrolysis. Five sittings only were required, and the author declares that this is not an isolated case, that he has cured in the same way many angiœmata of the face which appeared to be serious. He describes his technique very fully. When the patient is not docile, or when the angiœma is large, arterial, or situated in a dangerous region, general anæsthesia is necessary. Local anæsthesia is insuff-

ficient. The sittings should not be frequent. After the first sitting from two weeks to a month should elapse before the second, and the time between the subsequent sittings should be determined by the effect obtained.

**2. Bronchointestinal Autoinfection in the Newly Born.**—Londe classifies these affections as: 1, Combined forms; (a) with coincident localization; (b) with alternate localization, acute, subacute, and chronic, slight, serious, and very serious. 2, Disassociated forms; (a) with the respiratory manifestation isolated, but not primary; (b) with the gastrointestinal manifestation primary and isolated, each either acute, subacute, or chronic, slight, serious, or very serious.

#### LA SEMAINE MEDICALE.

**1. Graves's Disease and Its Treatment.**—Thomson states that no disease shows so many signs of a universally acting toxæmia. Its many derangements may be extreme, though no organic change accompanies any of them. He thinks the symptoms prove that one agent produces all the effects, and that the disease cannot be confounded with anything else. The nature and origin of its specific poison are wholly unknown. The chief cause of this ignorance is a want of knowledge concerning the physiology of the thyroid and its associated structures. The nature of the disease is complicated by the oc-

currence of two serious conditions which follow removal of the thyroid, namely, hyperpyrexia and tetany. The view that the disease is due to hypersecretion of thyroid juice is questioned. Proper medical treatment furnishes the best chance for recovery in severe or mild cases. Rest from both physical and mental exertion is the first requirement. Dark meat and shell fish must be avoided. The standard article of diet must be milk either fermented or peptonized, but never raw. Certain vegetables and cereals are permissible and most of the fruits. Medical treatment consists mainly in the persistent use of intestinal antiseptics.

**2. Adiposis Tuberosa Simplex.**—Anders defines this condition as constituted by the presence of a larger or smaller number of fat nodules, ranging in size from a bean to a hen's egg, in the subcutaneous tissue of the abdomen or the extremities. They do not fuse together, are not elevated above the surface, and are usually painful to the touch. The cause is the same as that of general obesity, and they are removable by the same treatment which will remove obesity. They are not associated with any glandular, mental, muscular, or nervous trouble. That they are caused, like adiposis dolorosa (Dercum's disease), by disease of the lymphatic structures, of the thyroid, or of the hypophysis, is deemed improbable on account of the mildness of their symptoms and the readiness with which they yielded in the four cases reported by the author to careful dietetic and regiminal treatment.

**3. The Choice of Operation in Pyloric Stenosis.**—Finney limits his discussion to the consideration of organic strictures, surgical treatment being always presupposed for such conditions. Pyloric stenosis in the adult usually originates from an ulcer. The choice of operation should depend partly upon the patient and partly upon the ability of the operator. If the condition is due to incipient cancer an attempt at extirpation should be made by the Billroth No. 2 method. If the obstruction is of benign origin the choice of operation will lie between gastroenterostomy, pylorotomy, pyloroplasty, and gastroduodenostomy. The clinical results which have followed gastroenterostomy by the "no loop" operation of Mayo have been very good, the object being to obtain good drainage of the stomach. The advantage of pyloroplasty is that it preserves the anatomical and physiological outlet of the stomach, and it is indicated in the author's experience in connection with dilatation of the stomach, dense adhesions, hypertrophy and cicatricial thickening of the stomach wall, acute and chronic ulceration, and pylorospasm. In forty-five cases the author has had very good results, and he prefers the operation to any other.

**5. Acute Glandular Fever.**—Jones defines this condition as an infectious disease, developing usually without preliminary signs, and characterized by slight redness of the throat, high fever, and swelling and tenderness of the lymph glands of the neck. Most of the reported cases have been in Germany and France. Puffer having described the disease as *Differential*. It may be endemic or sporadic. Twelve per cent. of the cases are in children. Exposing to cold and damp favors its development. Some writers suppose it is a peculiar form of adenitis. Its

incubation is five to seven days. Its onset is sudden, with headache, abdominal pain, anorexia, chills, constipation, coated tongue, pulse from 90 to 130, temperature 102° to 104° F. The enlargement of the glands begins from the second to the fifth day and persists, with more or less tenderness, two or three weeks. The spleen, liver, and mesenteric glands are also enlarged in many cases. Convalescence is usually uninterrupted. The differentiation must be from leucæmia, pseudoleucæmia, tuberculous adenitis, and syphilis, also from typhoid fever and influenza. The presence of Pfeiffer's bacillus determines the diagnosis.

**7. Tumors of the Cauda Equina and Lower Vertebrae.**—Spiller states that the diagnosis of these tumors must be between hysteria, multiple neuritis confined to the lower limbs, intrapelvic tumor, tumor or caries of the lumbar vertebrae or sacrum, lesions within the vertebral canal but external to the dura tumor or other lesion of the conus, and the condition which is under consideration. The pain with these tumors may be unilateral or bilateral. The functions of the bladder and rectum may be greatly impaired. Digestive disturbances and emaciation are late symptoms. Both anterior and posterior roots may be involved, and paralysis of motion and sensation ultimately ensue. The symptoms develop very slowly, but may be entirely disproportionate to the size of the tumor. With regard to surgical treatment, the operable tumors are those of the membranes that have not implicated the cord and are lipomata, fibromata, psammomata, echinococci, and exostoses.

**11. Specific Immunity and X Ray Therapeutics.**—Crane draws the following conclusions: 1. Such treatment may require sufficient intensity to set free in the tissues the equivalent of an autogenous vaccination. 2. The duration of exposure and extent of diseased tissue exposed should be so regulated as to induce a small negative phase or none at all. 3. The repetition of exposures should be governed by the duration of the negative and positive phases. If the disease producing agent in a given case is undetermined, one should follow the analogy of cases in which opsonic estimations can be made. The advantages of x ray over opsonic therapy are: 1. The immunizing substance set free by the x ray is autogenous, being formed from the actual microbe strain which is producing the disease. 2. Many of the difficulties and mistakes of a bacteriological diagnosis are eliminated. 3. If the bacteriological cause is undetermined or the disease producing agents are not bacteria, the x rays are still applicable.

2. Some Experiences with X Ray and High Frequency Treatment, By F. GARDINER.
3. The Recognition and Treatment of Incipient Mental Disease, By T. C. MACKENZIE.

**1. Notes on Immunity to Disease.**—Harvey and McKendrick review our vaccinotherapy. The applications are numerous. Some have been more successful than others. A tubercle vaccine—Koch's tuberculin—has been used for the cure of lupus, tu-

berculous glands, tuberculous sinuses, and genito-urinary tuberculosis. It has been also used in early cases of phthisis. A staphylococcus vaccine has been used for boils, acne vulgaris, syphilis, malignant endocarditis, certain cases of pyæmia, and other such affections due to this organism. A bacillus coli vaccine is useful in some cases of appendicitis, cystitis, and cholecystitis. It is quite possible that an efficient gonorrhoeal vaccine may be found which will be useful in chronic cases. We may hope for a dysentery vaccine, Malta fever vaccine, and pneumococcus vaccine.

1. Remarks on Empyema Based on a Series of One Hundred Consecutive Cases, By ALBERT E. MORISON.
2. The Symptoms and Ætiology of Mania (*continued*), By LEWIS C. BRUCE.
3. A Résumé of the Report of the Royal Commission on Human and Bovine Tuberculosis, By J. S. FOWLER.
4. Tumor of the Cauda Equina Removed by Operation: Recovery, By R. C. ELSWORTH.
5. A Review of Recent Work on Spinal Anæsthesia, By J. W. STRUTHERS.
6. Tropical Diseases: Notes on Some of the More Interesting Cases Recently Under Treatment in Edinburgh, By D. E. MARSHALL.

**1. Remarks on Empyema.**—Morison concludes from his observation of one hundred consecutive cases of empyema that pleuropneumonia is the most frequent cause of empyema, while it rarely follows pleurisy with effusion. In adults empyema is more likely than in children to be secondary to serious lung disease. The diagnosis of empyema is not always easy, for it may be ushered in by symptoms pointing more to the abdominal than the thoracic cavity, and the physical signs resemble closely those of consolidation. The exploring needle should be used in all doubtful cases, and, if needful, in more than one place, as there is no danger in using the needle with proper care. The immediate prognosis of an uncomplicated empyema treated by incision and drainage is good. It is worst when allowed to burst through the chest wall. The remote prognosis is excellent. No deformity follows recovery, and no sequelæ are to be anticipated. The best prognosis can only be given in cases where an aseptic condition of the pleural cavity can be assured by antiseptic operation and antiseptic after treatment. The anæsthetic should be carefully administered, and the patient not turned over during its administration; in adults it is safer to do the operation without general anæsthesia. Aspiration is disappointing as a curative agent, but is useful in some cases temporarily, while incision and drainage with antiseptic precautions may be trusted to cure all cases of curable empyema, but irrigation is unnecessary and dangerous. Rib resection is needful in some neglected cases, but in the generality of cases it is needless surgery.

**3. A Résumé of the Report of the Royal Commission on Human and Bovine Tuberculosis.**—Fowler reviews the report. The exact reference to the commission was to inquire and report: (1) Whether the disease in animals and man is one and the same; (2) whether animals and man can be reciprocally infected with it; and (3) under what conditions, if at all, the transmission of the disease from animals to man takes place, and what are the

circumstances favorable or unfavorable to such transmission. In the seven years which have elapsed since the commission was appointed, interest in the tuberculosis problem, so far from fading, has spread among all classes, and the observations and conclusions of the commission are of great importance in their bearing upon one of the practical questions of the day. The commission has not answered the first question referred to it, but it is able to give an affirmative reply to the second. The principal points drawn attention to in the conclusion of the report are: (1) That a certain amount of tuberculosis, especially in children, is directly due to infection with the bovine bacillus. (2) That tuberculous milk is clearly a cause of tuberculosis, and fatal tuberculosis, in man. (3) That a very large proportion of tuberculosis contracted by ingestion is due to bovine bacilli. (4) That more stringent measures are required to prevent the sale or consumption of milk from tuberculous cows.

### Proceedings of Societies.

#### PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting of Wednesday, January 22, 1908.

The President, Dr. A. M. EATON, in the Chair.

**Cancer of the Stomach.**—Dr. JOHN J. GILBRIDE exhibited a specimen of cancer of the stomach taken from a woman seventy-two years of age. The entire stomach was involved and was reduced to about one third the size of the normal organ. It was firmly adherent posteriorly. The pancreas was also involved as well as the transverse colon. Metastases were distributed throughout the great omentum. The woman had been under treatment by various physicians and at dispensaries and clinics for a period extending over four years. The various diagnoses given were gastritis, nervous dyspepsia, kidney disease, nervousness, etc. The case was illustrative of the lax methods of examination too often employed in such cases, since the woman, according to her own statement, had never been thoroughly examined, and her disease had not been recognized until within a few months of her death.

**Wanted, a Medical Bureau of Publicity, Especially for County Medical Societies.**—This was the title of a paper presented by Dr. J. MADISON TAYLOR. The profession of medicine, he said, was essentially an educational agency. It was still held by its nobler traditions to a dignified position of reticence. It was governed by ethical principles somewhat restricted and vague. Nevertheless, the question should be fairly met, "Did these ethical limitations accomplish the objects for which they were originally devised?" By not one jot or tittle would he assail the spirit in which they were conceived or mar the purity of those principles of right conduct, of conscientious protection of the home, or of mutual relationships between advisers and family long maintained. There was, however, ground for fear that in the wider field of relationships between the profession and the great world movements, gross misapprehensions had arisen. These misconceptions had long been a source of injustice, not alone to us,

but to those who needed our counsel. Much harm resulted.

The central aim of the profession of medicine was radically different from all other professions, callings, organized activities. Only a few individual representatives failed to adhere conscientiously to this aim. We stood as a unit sworn to use all the powers we possessed and could acquire to prevent the very causes of conditions which made our calling necessary. A secondary purpose was to cure or remedy with the utmost promptitude the baneful effects of these causes. In short, whereas all business enterprises endeavored to increase a demand, we strove to prevent, to check its growth. So much for the basis of our professional ideals, to which, with rare exceptions, all its exponents adhered.

Not so, however, with that immense force of commercial auxiliaries grown up alongside, viz., the purveyors of articles which we used in our work, drugs, remedial agents, waters, various appliances, and lately special foods, *et id omne genus*. The watchword of these men was not only to supply all demands, but to apply progressive business principles to their enterprises and keep the demand not only active, but overactive, to create a demand, legitimate or artificial. They assumed to teach us and form opinions for the public. Here was a grave peril for which we were partly responsible by omitting to insist upon needful precautions.

It is most difficult to compete with shrewd merchants in distinguishing between statements based on truth and those which were adroitly cited to sustain fictitious demands or to encourage excesses of supply. Above all, we should aid in promulgating right conceptions of the advances in medical science. The agency we must use was the public press. Here, upon this recognized arena, with the great body of thinking people as an audience, must we stand to win or lose on truth as our inspiration, on ethical principles as rules of the competition, on our sincerity of purpose to benefit our fellow man as the banner of our cause.

In his opinion it was necessary to meet modern conditions by adopting modern methods. Every form and kind of opponent to the purposes and efforts of the profession made use of the newspapers to reach the attention of the people. The whole crew of fakirs, grafters, panderers to evil amusements, venders of disguised poisons, and all the disseminators of hurtful influences employed vast sums of money through press agents of one kind or another. The one available means of combating these destructive agencies was for organized medical bodies to establish bureaus of publicity, safeguarded by competent committees, through which information, opinions, action should be accurately and systematically supplied to the papers. The public were made fully aware of every tempting method of doing themselves harm. We, as a profession, failed to exert the countervailing influences which ought to impress the consciousness of those who needed our protection. Every large city should have a medical editor, to whom matters of polity should be referred. He had better be a busy practitioner, too, not one whose professional activities had ceased.

The author would propose the establishment of medical bureaus of publicity in connection with all

county medical societies. A reliable press agent should be retained. Many and varied reasons could be adduced why these were absolutely essential to secure a correct presentation of facts bearing upon the integrity of medical science and the best interests served by the conservators of public and private health. Among the most important of these was the well known fact that all those interests which were diametrically opposed to medical ethics did employ press agents. With them it was a question of business. Good business methods demanded that the public should be made acutely aware of the more attractive phases of the proposition offered. These fakirs had goods to sell, advice, or whatever they wished to barter for money. The chief avenue of diffusion was the daily press, through the ordinary channels of advertisement or shrewdly placed news items. For example, it was well known that the great nostrum vendors expend many millions of dollars annually, and through the intelligent cooperation of professional press agents. These constituted practical bureaus of publicity for quackery. No organized medical body in the world spent one cent for popular education, to "put the people wise" on questions it was their desire and duty to have correctly understood. Yet a large and increasing group of irregulars did spend vast sums to mislead the unwary, thereby causing incalculable damage to morality and health.

Teaching mankind systematically and accurately how to know good from evil, right interpretations of current facts, advancements in scientific knowledge of hygiene, correct living and acting, should be the undivided purpose of the profession of medicine. The first step was to get the real facts known, to teach the people correctly what we were doing for their welfare, to furnish information of a kind calculated to advance the best interests of the race. The form and character of such bureaus of publicity should be carefully formulated. Rules to govern methods, however, should be revised repeatedly and promptly, until, by intelligent evolution, consonant with experience, they became perfected.

Dr. JOHN G. CLARK, chairman of the Board of Public Education of the American Medical Association, spoke of the plans being formulated by the board in the matter of educating the public upon medical matters. Educators and editors generally had taken the most enthusiastic view of the question. A large number of subjects really required public exploitation, and efforts were being made to have the large magazines and the agricultural and other papers publish articles bearing upon such subjects. It was the aim of the board that all the articles published for lay people should be bound together or in pamphlet form. In the event of an outbreak of typhoid fever, if necessary, a certain district might be flooded with literature drawing attention to the necessity of disinfection of water and bearing upon general principles, but not upon treatment. For advice as to treatment any person would be referred to his family physician. It was the object of the board to take up the broader phases of medicine; possibly the history of medicine would be considered. All articles would be unsigned.

Dr. A. B. HIRSH felt that the proposition of Dr. Taylor to have the Philadelphia County Medical

Society name a Committee on Publicity should take practical form, and referred to similar work done by one of the other county medical societies of the State.

Dr. JAY F. SCHAMBERG believed that medical bodies should have publicity or press bureaus, that the work could be done in such a manner as to prevent any abuse, and that it would result in a vast amount of good to the public. He gave credit to Dr. Taylor for his courage in braving the attitude of the medical profession by the publication over his name of articles in the public press which he thought were for the public welfare. It seemed to Dr. Schamberg feasible to have a bureau of publicity composed of prominent men in the society who could revise reports given out to the press for publication.

Dr. CHARLES A. E. CODMAN endorsed the paper of Dr. Taylor, but thought that, since such work was to be done by the American Medical Association, it seemed unnecessary that each county society in Pennsylvania should have such a committee or bureau working independently. He would favor a plan whereby the State society should have the general control of all the subsidiary bureaus in the State, with the committee of the State society working in connection with that of the American Medical Association. He believed there should be such a bureau of publicity, but that the profession should work together, thereby making its power felt.

**The Importance of an Ocular Examination in Pregnant Women Manifesting Constitutional Signs of Toxæmia.**—Dr. WILLIAM CAMPBELL POSEY and Dr. JOHN COOKE HIRST referred in this paper to the value of an ocular examination, not only in pregnant women who had albumin in the urine, but also in cases of toxæmia where the urine showed no traces of albumin. This happened when the liver or other organ apart from the kidney was unequal to the task put upon it by the excessive tissue changes, or when the kidneys, though diseased, had not as yet excreted albumin. They pointed out that the quantitative estimation of urea was not always of value in proving a toxic state of the system, careful studies of which were made upon groups of patients at the Maternity of the University of Pennsylvania showing that the urea varied from 0.1 to 3.5 per cent. in patients each of whom received exactly the same amount of food. They insisted that obstetricians should appreciate two facts; first, the changes in the fundus of the eye which had been occasioned by renal disease, and were almost certainly diagnostic of renal disease, might precede the presence of albumin in the urine; and, second, that the ophthalmoscope might give evidence of disease other than of the kidneys which has been excited by the toxæmia of pregnancy.

While the renal condition which arose in pregnancy was an acute condition, it was not unlikely that chronic nephritis might have existed in many cases prior to pregnancy. An examination of the fundus under these conditions revealed in most instances disease of the retinal vessels, and served to put the obstetrician on his guard. The writers reported all the cases found in literature of ocular

changes which had been noted in women who were pregnant, but whose urine did not contain albumin. They pointed out that, the diagnosis of toxæmia once made, the question of saving the life of the mother must be considered. Sillex concludes that when retinitis developed in the first months in cases in which chronic nephritis had previously existed in a latent form, but had been set into activity by pregnancy, labor should be at once artificially induced, for not only was the life of the mother jeopardized, but there was present the possibility of blindness. In the acute nephritis of pregnancy he considered the prospect for sight during the progress of pregnancy none too favorable. The prognosis for sight in cases in which the ocular changes had been induced by the renal toxæmia of pregnancy had been well established, Culbertson's figures recording blindness in 24.99 per cent., partial recovery of sight in 58.31 per cent., and recovery of sight in 16.66 per cent. of the cases. Sillex's tables showed blindness in twenty-five per cent., partial recovery of sight in forty-seven per cent., and recovery of sight in twenty-nine per cent.

The writers reported a case of toxæmia during pregnancy where the ocular symptoms, which were the only demonstrable signs of the disease, also the general symptoms, disappeared promptly after the artificial induction of labor. The urine was free from albumin at all times, and the general symptoms were few, and had the ophthalmoscope not revealed the malignancy of the toxæmia, it was probable that labor would not have been interrupted, and it was not unlikely that the patient would have died of eclampsia. Active eliminative treatment gave no relief. Dr. Hirst then induced labor artificially. The general symptoms disappeared at once and the ocular changes after some weeks. A year had elapsed since the termination of the pregnancy. The general condition of the patient was somewhat abnormal, and though there had been no recurrences of the retinal travassations, the retinal vessels appeared unhealthy, being unduly full and tortuous, awaking the suspicion of a disease of their walls. Nothing abnormal had been found in the urine, and the patient's physician was inclined to regard the toxæmia as a result of the failure of the liver to perform its functions properly, the patient's father having died of hepatic cirrhosis, and there having been great tenderness over the whole liver until after the expulsion of the fœtus.

Dr. GEORGE E. DE SCHWEINITZ said that the recent work of Berger and Loewy stated that the ocular complications of pregnancy might arise: (a) from pressure of the gravid uterus on the circum-uterine nerves, causing reflex symptoms; (b) from qualitative changes in the blood; (c) from auto-intoxication, which in its turn might arise from fermentations in the intestinal tract, or from new toxic substances which came from the fœtus, the placenta, insufficiency of the kidneys, or atony of the bladder. Finally, the cessation of menstruation during the pregnant period, according to Charrin and Roche, was capable of originating metabolic products which otherwise would be eliminated, added to which there might be an insufficient action of the antitoxic active glands, especially of the liver. It was, therefore, evident that the pathways were

numerous, and the statement of Winckel that in 1.6 per cent. of pregnancies some disorder of the visual organs could be found was well within the possibilities. Naturally, the most important ocular complication was the development of the albuminuric retinitis of pregnancy, to which the paper of the evening did not specially refer, and which was so sure a sign of serious disorder that the question of inducing premature labor must immediately be seriously discussed, if the eyesight of the patient was to be saved. An equally important matter, however, was to determine whether or not there were other ophthalmoscopic signs which might be of service to the obstetrician if widespread retinal lesions were absent, and if frequent examinations failed to show albumin in the urine. Dr. de Schweinitz observed that thus far there was no ophthalmoscopic picture which is diagnostic, although, as the essayist had pointed out, neuritis and neuroretinitis, retrobulbar neuritis, and retinal hæmorrhages might develop without the presence of albumin; and if they were present, they furnished potent reasons for the most searching investigation and for a discussion of the necessity of interference with a view to terminating the pregnancy. He believed it probable that certain types of auto-intoxication, although the whole subject was surrounded with much uncertainty, played an important rôle in the production of those ocular complications which were not directly the result of a kidney lesion. He felt that ophthalmologists and obstetricians should work together in order that one might be helpful to the other, and, if possible, the ophthalmoscope be utilized to detect changes which the ordinary clinical examinations failed to reveal.

**Gastroenterostomy in Cancer of the Stomach, with Reports of Two Cases; also a Third Case Diagnosed by Examination of Shreds of Tissue which Came Away During the Use of the Stomach Tube.**—Dr. JOHN J. GILBRIDE described three types of onset of cancer of the stomach, and emphasized the very great importance of employing every method to make an early diagnosis, stating that even the suspicion of cancer justified an exploratory laparotomy. Three cases were reported. One was of six months' duration, in which anterior gastroenterostomy was performed. The patient lived for four months after the operation and had been able for two months to do light work. Of the two other patients, one gave a history of indigestion extending over a period of fourteen years. This disturbance the author attributed to ulcer. Posterior gastroenterostomy was done in this case on August 27, 1907, and, although the patient died in the latter part of October, there had been no further stomach symptoms. She ate her food well, but did not recover her strength. The third case reported illustrated three points: 1. Diagnosis of cancer by examination of a piece of tissue that came away in the wash water during the use of the stomach tube. 2. Absence of lactic acid. 3. A clear history of ulcer of the stomach dating back twenty-eight years. This patient declined an operation. In this case the diagnosis of cancer of the stomach would not have been made without the use of the stomach tube, since there were a floating kidney and conditions which

would readily have accounted for the stomach symptoms.

Dr. Gilbride pointed out that lactic acid was never present in the early stages of the disease, and that in many instances the presence of cancer was not suspected until there were bloody vomit and a tumor. The method of choice in the performance of gastro-enterostomy was said to be the posterior no-loop method with a double row of sutures, with the jejunum continuing its normal course to the left. When adhesions and other conditions did not permit of the posterior operation the anterior anastomosis should be done. In the presence of the anterior operation enteroenterostomy should be performed. The anastomotic opening in the stomach should be so far distant from the line of apparent invasion of the disease as to prevent the early involvement of the stomach by the disease. Contraindications to operation were involvement of the supraclavicular lymph glands, particularly of the left side, other extensive involvement, and advanced cachexia and ascites.

Dr. JOHN B. DEEVER agreed with Dr. Gilbride that the results were very good if an operation was done early, but very bad if it was resorted to late in the disease.

### Letters to the Editors.

#### A PROBLEM IN APPLIED ETHICS.

##### To the Editors:

Dr. A. was engaged to attend a confinement in the family of a farmer who had recently moved several miles out from the village in which he resided to a place about halfway between the village and a neighboring borough. Dr. A. bespoke the services of Dr. B., of the borough, as alternative, to the entire satisfaction of the family. Dr. B. had permanent arrangements with Dr. C. to visit certain cases in his absence, being an established physician with hospital appointments. Dr. C. was a recent graduate.

When the day came Dr. A. was in a distant State after big game, and Dr. B. was in the great city attending to operations. By a rapid interchange of telephone messages Dr. C. was promptly put on the road. He was an utter stranger and unwelcome. The case was tedious and complicated, being that of a primipara of above thirty. Anæsthesia, help, and an operation for laceration were required. Dr. C. secured the aid of Dr. D., another stranger, and the two gave the day to the requirements of the case. Mother and child did splendidly.

Here is the problem: Who should send the bill for service? Who should pocket the fee? Who should ultimately share it?

While I have my pen in hand let me add a few facts relative to the financial and the ethical, or the nonethical, sequel of this case. According to an agreement between Dr. B. and Dr. C., the latter sent a bill, expecting to compensate his assistant. Both needed it, and had nobly merited what was asked. The farmer had employed Dr. A. and looked to him for the bill. He would have no dealings with Dr. C. Dr. A. spoke hot words against the doctor who dared bill a family of his! Just before they

lighted the candles to adorn the birthday cake on that child's fourth birthday Dr. A. produced the bill and quiet payment was made.

The writer was merely an interested onlooker. What is good ethics in such a case? I ask not to puzzle, but to learn. READER.

### Book Notices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

#### *The Diagnosis and Treatment of Pulmonary Tuberculosis.*

By FRANCIS M. POTTENGER, A. M., M. D., Medical Director of the Pottenger Sanatorium for Diseases of the Lungs and Throat, Monrovia, Cal., Professor of Clinical Medicine, Medical Department, University of Southern California, etc. New York: William Wood & Co., 1908. Pp. xiv-377. (Price, \$3.50.)

Our readers are well aware of Dr. Pottenger's title to write on tuberculous pulmonary disease, for he has contributed valuable material concerning the subject to our columns. In this work he has treated of it very thoroughly and in a most scientific manner. There are, however, some questions of interest which he hardly discusses—for example, that of the relations between bovine and human tuberculous disease, that of the comparative frequency of infection by the air passages and the alimentary canal, and that of Dr. John B. Murphy's proposal to give prolonged rest to a diseased lung by keeping the pleural sac distended with nitrogen.

The author does well, we think, to call particular attention to the fact that a long time may elapse between infection and the appearance of frank signs of tuberculous disease. Concerning heredity, he says: "Since the overthrow of the theory of heredity as the cause of tuberculosis, the importance of the family history has declined. While it seems well established that there are very few instances in which tuberculosis has been transmitted directly from parent to offspring, nevertheless, family history is important as an index of resistance to disease, and as it bears upon the longevity of the patient." This seems to us judicious teaching.

The necessity of an early diagnosis is urgently insisted on, the author intimating that it is little short of criminal to wait until bacilli are found in the sputum, and especially to keep back the truth from a patient, so that time is wasted in a false sense of security. There should be perfect frankness, he says, between the physician and the patient. The matter of diagnosis is considered almost exhaustively, and the author is at great pains to set down the minutiae of the physical signs. Excessive carefulness, it seems to us, is shown in this sentence: "When the mouth is used, the temperature should not be taken for at least a quarter of an hour after drinking or eating; and, if the patient has been drinking anything very hot or very cold, the temperature of the mouth may be influenced for a still longer time." However, it can do no harm to wait to the extent recommended. The use of tuberculin as a diagnostic test is squarely advo-

cated, but he thinks that the practical value of the conjunctival reaction to tuberculin "needs further confirmation."

The establishment of immunity is regarded by Dr. Pottenger as the keynote to the curative treatment, and he handles in a masterly way such matters as the action of fresh air, the influence of diet, rest, and exercise, climate, hydrotherapeutics, sanatorium treatment, and even Bier's hyperæmia. He deals, too, most instructively with the subject of prophylaxis. He takes a very favorable view of the careful therapeutic use of tuberculin, and regards Wright's work under the guidance of the opsonic index as having done more than everything else to establish the efficiency of the tuberculin treatment. The treatment of individual symptoms and the management of complications are well set forth; so also are the results of treatment and their permanence.

In short, we do not see how more valuable teaching in regard to a disease that is now meeting with the earnest attention of the whole civilized world could well have been given within the moderate compass of Dr. Pottenger's work.

*Textbook of Otology for Physicians and Students.* In Thirty-two Lectures. By FR. BEZOLD, M. D., Professor of Otology at the University of Munich, and FR. SIEBENMANN, M. D., Professor of Otology at the University of Basle. Translated by J. HOLINGER, M. D., of Chicago. Chicago: E. H. Colgrove Company, 1908. Pp. 314.

In the form of a series of clinical lectures Bezold presents the developments of the last twenty-five years in otology. The volume is naturally more suited to students and general practitioners, as the author intended it should be, than for the aural surgeon. Most stress is accordingly laid on the anatomy and physiology of the organ of hearing, clinical examination of the ear, functional tests, and the pathology of otitic disease. The operative procedures and the details of surgical technique are limited to those which the general practitioner might be called on to perform. Major operations are to be studied practically. The volume is an interesting and instructive one for those who wish to familiarize themselves with the principles of otology and with the routine of scientific examination of the organ of hearing. It is hardly a textbook of otology in the sense of presenting the entire field. Holinger's translation is adequate, but rather crude.

*Les Ferments métalliques et leur emploi en thérapeutique.* Par Professeur ARMAND ROBIN, membre de l'Académie de médecine. Paris: J. Rueff, 1907. Pp. 252.

In this volume Robin presents a résumé of the studies he has made on the therapeutic action of certain metals which have been administered in a highly divided condition. The results of these investigations have been published from time to time since 1901; and, as Robin alleges in his introduction, have been received with considerable incredulity, which, it may be remarked in parenthesis, has not been allayed in many quarters even at the present time. This incredulity, however, has attached itself more to the methods announced than to the general factors of the problem since these latter have received so much more thorough study from the laboratories of other students.

Robin then takes up in a sketchy fashion the re-

lation of the ferment action of metals to that type of action seen in the organic enzymes. Then he develops the physiological and therapeutic indications of the metallic ferments and medicinal serums. The treatment of pneumonia, bronchopneumonia, articular rheumatism, acute meningitis, and various infections, acute and chronic, are then taken up, and therapeutic optimism throws caution and even good sense to the winds. His results and conclusions often show the attitude of the special writer on a Sunday edition of a metropolitan journal, and the reviewer feels that the author's conclusions should be taken *cum grano salis*.

*Diseases of the Genitourinary Organs and the Kidneys.* By ROBERT HOLMES GREENE, A. M., M. D., Assistant Professor of Genitourinary Surgery, Medical Department of Fordham University, etc., and HARLOW BROOKS, M. D., Assistant Professor of Pathological Anatomy, University and Bellevue Hospital Medical School, etc. With 292 Illustrations. Philadelphia and London: W. B. Saunders Company, 1907. Pp. 536.

A surgeon and a pathologist have joined efforts in producing this newest textbook on genitourinary diseases. In some ways the book of Greene and Brooks does not differ materially from the older works, but in other respects it marks perhaps a step in the evolution of urology in this country. In the first place, much more space is devoted in it to purely urinary diseases, and far less to sexual or venereal conditions. This is in accordance with the tendency of urology to ascend higher in the tract, from chancres and gonorrhœa toward the kidneys. In this respect and in some others the present volume is distinctive among American genitourinary treatises. It is perhaps the first work which gives space to a marked extent to the ideas and views of the new French and German, particularly the German, schools of urology. Frisch and Zuckerkandl's great work, *Handbuch der Urologie*, has evidently been freely used in the composition of the text, without, however, any suggestion of direct translation. One might say that the authors had "caught the flavor" of the German work rather than that they had imitated it.

We are sorry to find that some of the plates are not credited as they should have been, such, for instance, as those showing cystoscopic images, which bear a close resemblance to the plates of Nitze and of Frisch and Zuckerkandl. In dealing with functional renal diagnosis but two methods are mentioned, the phlorrhizin test and the methylene blue test. Nothing is said of Voelcker and Joseph's indigo-carmin test, which, according to Kapsomer, has practically superseded the methylene blue test since 1903. Albarran's method of "experimental polyuria," a most important one, is also not mentioned. Nothing is said of the fallacy involved in the methylene blue test, owing to the fact that the dye is often excreted as a colorless "chromogen" or "leuko" product. This section needs revision, and its contents should be made more intelligible to the average student.

The surgical and the pathological aspects of the subject are well handled. The illustrations are clear cut, simple, and helpful. The text is well arranged, and the style is not cumbersome or prolix, but adapted to the comprehension of beginners.

As a whole the book is one of the most serious

tory and useful works on genitourinary diseases now extant, and will undoubtedly be popular among students and practitioners.

*Der Abstinenzismus und seine Bedeutung für das Individuum und für die Gesellschaft.* Von Dr. GUSTAV KABRHHEL, a.o. Professor der Hygiene, Vorstand des hygienischen Institutes der böhmischen Universität und der staatlichen Untersuchungsanstalt für Lebensmittel in Prag. München und Berlin: R. Oldenbourg, 1907. Pp. 69.

The alcohol question, which was hardly known in central and northern Europe about twenty-five years ago, lately has come very much indeed to the foreground. Leading in this respect was Norway, to be followed by Sweden, Denmark, Germany, and Austria.

Professor Kabrhel speaks in his book of the influence of alcohol upon the human body; the dependence of this influence on the method and form of using alcohol, on the power of resistance of the body, on the muscle activity, and the climate; and finally describes facultative and absolute temperance. He thinks that absolute abstinence is not unconditionally necessary. The only safeguard against the evil sequelæ of excess in eating and drinking is the use of simple foodstuffs; alcohol does not belong to the simple foods, and should therefore not be included in the daily fare. If one wishes to change the monotony of such simple fare he should partake moderately of a richer meal with some wine or beer. But this breaking of the rule should only be an exception.

But, concludes the author, the best results are obtained in countries where no concessions are made by the enemies of alcohol, and where the principle of absolute abstinence is carried out.

#### BOOKS, PAMPHLETS, ETC., RECEIVED

*Rotunda Midwifery for Nurses and Midwives.* By G. T. Wrench, M. D., Late Assistant Master of the Rotunda Hospital. With Introduction by the Master of the Rotunda Hospital. London: Henry Frowde (Oxford University Press) and Hodder & Stoughton, 1908. Pp. xiv-324.

*The History of the Study of Medicine in the British Isles. The Fitzpatrick Lectures for 1905-6, delivered before the Royal College of Physicians of London.* By Norman Moore, M. D., Cantab., Fellow of the Royal College of Physicians, etc. Oxford: The Clarendon Press, 1908. Pp. vi-202.

*Bericht über die Thätigkeit des temporären Lazareths am Golitzyn-Hospital in Moskau während des russisch-japanischen Krieges (18. Juni 1904-10 April 1906).* Von Dr. S. Derugin, Chefarzt des Golitzyn-Hospitals in Moskau. Mit 5 photographischen und 37 Röntgen-Aufnahmen. Herausgegeben auf persönliche Kosten der Fürstin Anna Alexandrowna Golitzyn. Moskau: S. P. Jakowlew, 1908. Pp. 159.

*Medical Lectures and Aphorisms.* By Samuel Gee, M. D., Fellow of the Royal College of Physicians, Honorary Physician to H. R. H. the Prince of Wales, etc. London: Henry Frowde (Oxford University Press) and Hodder & Stoughton, 1908. Pp. viii-308.

*Clinical Lectures and Addresses on Surgery.* By C. B. Lockwood, Surgeon to St. Bartholomew's Hospital. London: Henry Frowde (Oxford University Press) and Hodder & Stoughton, 1907. Pp. viii-307.

*The Mellin's Food Method of Percentage Feeding.* Boston: Press of the Mellin's Food Company, 1908. Pp. 183.

*Applied Physiology. A Manual Showing Functions of the Various Organs in Disease.* By Frederick A. Rhodes, M. D., Professor of Physiology and Embryology, Medical and Mental Departments of the Western University of Pennsylvania, etc. Pittsburgh, Pa.: Medical Press, 1907. Pp. 206.

*A Textbook of Physiological Chemistry.* By Olaf Hammarsten, Late Professor of Medical and Physiological Chemistry in the University of Upsala. Authorized Translation, from the Author's Enlarged and Revised Sixth German Edition, by John A. Mandel, Sc. D., Professor of Chemistry in the New York University and Bellevue Hospital Medical College. Fifth Edition. First Thousand. New York: John Wiley & Sons, 1908. Pp. 845.

*Syphilis. A Treatise for Practitioners.* By Edward L. Keyes, Jr., A. B., M. D., Ph. D., Clinical Professor of Genitourinary Surgery, New York Polyclinic Medical School and Hospital, etc. With Sixty-nine Illustrations in the Text and Nine Plates, Seven of which are Colored. New York and London: D. Appleton & Co., 1908. Pp. xxix-577.

*A Textbook of Minor Surgery.* By Edward Milton Foote, A. M., M. D., Instructor in Surgery, College of Physicians and Surgeons (Columbia University), Lecturer on Surgery, New York Polyclinic Medical School, etc. Illustrated by Four Hundred and Seven Engravings from Original Drawings and Photographs. New York and London: D. Appleton & Co., 1908. Pp. xxvi-752.

*A Mind That Found Itself. An Autobiography.* By Clifford Whittingham Beers. New York and London: Longmans, Green, & Co., 1908. Pp. viii-363.

*The Functional Inertia of Living Matter. A Contribution to the Physiological Theory of Life.* By David Fraser Harris, M. B., M. D., B. Sc., F. R. S. E., Lecturer on Physiology and Normal Histology in the University of St. Andrews, etc. London: J. & A. Churchill, 1908. (Through P. Blakiston's Son & Co., Philadelphia.) Pp. 136. (Price, \$2.)

#### Miscellany.

**An Appeal to American Physicians.**—During the year 1907 over 200 papers, lectures, and pamphlets were published in Europe and America, presenting different phases of alcoholism and inebriety, purely from a scientific point of view. Many of the authors complain that these papers were not widely read and were practically lost, because they did not reach medical men interested in the subject. The Federation Bureau of this country, organized nearly two years ago, for the purpose of collecting and disseminating all facts concerning the alcoholic problem, in connection with the International Bureau in Europe having the same purpose, proposes to secure a list of medical men and scientists interested in the scientific study of the alcoholic problem. This list is to be made available for authors and students who write on this subject, and who wish to address a special audience of physicians, not only to increase their interests, but to stimulate further studies of the subject. Such a list will enable the bureau to extend its work of accumulating facts from the most reliable sources, and keep both authors and readers in close touch with all that is done. This is a practical effort to group and concentrate the experience and observation of medical men, and make them acquainted with what is being done in the scientific study of the alcoholic phenomena. All physicians who are interested in the scientific literature, research work, and studies of medical men at home and abroad are urged to send their names and addresses for registration, and also to receive copies and abstracts from authors and persons who may wish to have their work read and examined by interested parties. As chairman of the board of directors of the Federation Bureau, I urgently request every physician interested in this subject to send me not only their own names, but lists of reputable

physicians who would care to receive some of this most important literature coming from the press, and hear what is said in the scientific world concerning this problem.

(Signed) T. D. CROTHERS, M. D., Chairman,  
Hartford, Conn.

### Public Health and Marine Hospital Service

#### Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon general, United States Public Health and Marine Hospital Service, during the week ending January 20, 1908:

Places	Date.	Cases.	Deaths.
Alabama—Mobile.....	Feb. 1-20.....	6	2
California—Los Angeles.....	Feb. 22-29.....	2	2
California—San Francisco.....	Feb. 22-29.....	8	1
Illinois—Chicago.....	Feb. 29-Mar. 7.....	3	1
Illinois—Springfield.....	Feb. 27-Mar. 5.....	7	1
Indiana—Elkhart.....	Feb. 29-Mar. 7.....	3	1
Indiana—Marion.....	Feb. 1-20.....	54	1
Iowa—Cedar Rapids.....	Feb. 1-20.....	5	1
Kansas—Kansas City.....	Feb. 29-Mar. 7.....	2	1
Kansas—Wichita.....	Feb. 1-Mar. 7.....	57	1
Kentucky—Covington.....	Feb. 29-Mar. 7.....	1	1
Kentucky—Lexington.....	Feb. 1-20.....	1	1
Louisiana—New Orleans.....	Feb. 29-Mar. 7.....	11	6 imported.
Michigan—Detroit.....	Feb. 29-Mar. 7.....	7	2
Minnesota—Winona.....	Feb. 29-Mar. 7.....	1	1
Missouri—Kansas City.....	Feb. 29-Mar. 7.....	1	1
Montana—Butte.....	Feb. 25-Mar. 3.....	3	1
